But it were in the highest degree unphilosophical to consider the optical mechanism of the eyeball as constituting the whole of the organ of vision. The chief purpose of the optical mechanism is to render the images very much smaller than the objects. If we were unprovided with this reducing apparatus we could only see a very fractional portion of our surroundings at one time. We can conceive an eye without a dioptric apparatus, but we cannot conceive it without a retina—without a nervous screen for the reception of impressions, or without a nervous centre for their appreciation. A camera without sensitive plates and certain chemicals is a mere collection of lenses far less essential for photographic purposes then the plates themselves. Some sort of a photograph can be made by the plates without a camera, but no sort of photograph can be made by the camera without the plates. In like manner the dioptric contrivances of the eyeball—the lens, the humours, the mechanism of accommodation—are valueless by themselves; the final cause of their existence is the large mass of intra-cranial nerve structure that is concerned in the function of sight. Rightly considered, the eye begins in the orbit and ends in the occipital lobes. The retina, I may remind you, lines the eyeball; the optic nerve-fibres, collected into a bundle, pass through the sclerotic ring, and thence into the cavity of the cranium as far as the chiasma. Here a partial decussation takes place. The fibres from the temporal half of the retina proceed to the same side of the brain along the optic tract; those from the nasal retina crossing to the opposite side, thence to the corpora geniculata, and upwards through the white substance of the brain to the grey matter of the occipital lobe. Now, disease anywhere along this tract will give rise to visual disturbance or even blindness, and when the lesion is limited, indications of its position are afforded by the character of the sight affection. Thus, a lesion situated anywhere between the chiasma and the occipital lobe will affect the function of the nasal retina of the opposite eye and the temporal retina of the eye on the same side; the patient sees only the half of objects. You will remember a temporary condition of this sort that occurs in the course of those curious nerve-

Digitized by Google

storms called migraine. But we are not confined to inference alone. A portion of this nerve structure is visible. By means of the ophthalmoscope the retina and the optic disc can be seen and their pathological changes noted during life. By actual observation we have learned that inflammation is likely to be followed by atrophy. Atrophy means blindness—the *gutta serena* of the old authors—the disease that probably plunged Milton into darkness for half his lifetime. You will have to make yourselves thoroughly acquainted with the appearance of inflamed nerve-surface; not necessarily because it is part of ophthalmic medicine, but because it is of the utmost value as a diagnostic sign in nervous diseases. The nerves lie, as you are aware, in close proximity to the membranes of the brain; indeed, their sheaths are derived from those membranes. Meningitis is a common disease; not only pronounced meningitis, with its frightful array of symptoms and its fatal termination, but partial meningitis, involving only small patches at the base of the brain. It has been found that inflammation of the meninges—invisible, and only to be inferred from symptoms—has a distinct tendency to spread downwards and cause optic neuritis, which can be seen with the ophthalmoscope. Again, it has been found that a tumour of the brain—any kind of lump, whether formed by a strumous deposit, a malignant growth, or a syphilitic gumma—may give rise to neuritis. Hence it has become part of the commonplace of medicine that all cases of severe or persistent headache should be examined with the ophthalmoscope. Persistent headache with double optic neuritis is strong presumptive evidence of coarse disease of the brain. The ophthalmoscope enables us to see the actual extension of a process that is taking place far back within the cranium. I need not dilate on the enormous value of this fact. If the ophthalmoscope could do nothing else for us, this would make it an instrument of extraordinary use in diagnosis. These instances are sufficient to show you how ophthalmology contributes to the general efficiency of medicine.

Besides the essential portions of the organ of sight contained in the orbit and within the skull, we have certain accessories in the shape of muscles: the extrinsic muscles, to direct the movements of the eyeballs; and the intrinsic muscles, that affect the iris and lens. These are governed by very important nerves—the third, fourth, and sixth; and I shall have to show you that the movements of the eyeball and its focussing apparatus are often affected in such a manner as to give rise to optical difficulties.

If I have succeeded by these instances, hastily sketched out, in making my meaning clear, you will perceive that ophthalmology inclines on the one side towards the science of optics, and on the other towards neurology. I wish to impress upon your minds this borderland character of our study, because it gives you a clue to the direction in which we shall travel, and also because it shows that ophthalmology is not something separated from what you have already learned, but an additional aid to you in the most general work. I propose in this place to impart to you such instruction as may give you a clear view of your subject. I have already shown you that scarcely any lesion can occur to the visual organ in the orbit, the brain, or the accessory nerves and muscles, without producing optical disturbances. Some instruction therefore in the principles of the dioptrics of the eyeball you must have. Without such instruction you will be liable to err even in what may seem at first sight purely medical cases. I have already said that double optic neuritis and headache may presage coarse intra-cranial disease. But the same symptoms may be present, and on investigation prove to be due to a short antero-posterior diameter of the eyeball (hypermetropia). The prognosis between a case of cerebral tumour and a case that can be cured by a pair of spectacles is of course widely different, and yet the wrong opinion may easily be given. In the same manner an enormous proportion of cases of trigeminal neuralgia, that are even now too frequently treated with quinine, arsenic, belladonna, gelseminum, &c., are due to the same or a similar error of refraction, and are also curable by glasses. And squint, which is often thought to depend upon teething or worms, or the oblique example of a nurse-girl's eye, is in the majority of cases merely a condition of development, determined by an error of refraction, and curable by its correction. Thus you will see the optical and nutritional functions of the eyeball are inseparably yoked together, and the one reacts upon the other, so that cause and effect frequently appear to change places, and the beginning in one case is the end in another.

ACUTE PARENCHYMATOUS MYOCARDITIS.

By SAMUEL WEST, M.D., F.R.C.P.,

PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK, AND TO THE ROYAL FREE HOSPITAL; MEDICAL TUTOR AND MEDICAL REGISTRAR TO ST. BARTHOLOMEW'S HOSPITAL.

(*Continued from page 198.*)

CASE 3.—Eliza S——, aged twenty-four, single, was admitted on February 19th into St. Thomas's Hospital. She had been quite healthy up to the present attack. On February 15th she was seized with pain in her great toe, and on the 16th she could not walk, as her feet and knees were swollen and painful. On admission she had pain in both knees, both hands, and both wrists, with considerable effusion. She complained also of pain in the precordial region. Pulse feeble, 100; respiration quick and shallow, 60. Heart's impulse, the apparent apex, felt on a level with and just within the nipple. There was also pulsation, wave-like, in the left third intercostal space; superficial dulness increased a little upwards, reaching the nipple on the left, but scarcely if at all beyond the left edge of the sternum towards the right; heart's sounds somewhat muffled, but no murmur and no friction (? pericardial effusion, but, if any, very slight). No cough; tongue dry and coated; thirsty; appetite bad; sleeps badly; no headache; urine acid, slight trace of albumen. She was ordered ten grains of Dover's powder, fifteen grains of bicarbonate of potash, and ten minims of tincture of hyoscyamus, in an ounce of camphor-water, every four hours. — Feb. 20th: Pulse 144, small. Heart-sounds very feeble; no murmur; no friction. Pain less. Had a bad night. Patient looks very pale and anxious, complexion having a bluish tint. Has been very sick this morning. The vomiting was thought to be cardiac, and the patient was ordered a blister to the pericardium and some brandy. She got better and the vomiting ceased. At 4.45 P.M. her friends raised her up a little in bed to give her some food, and she fell back dead.

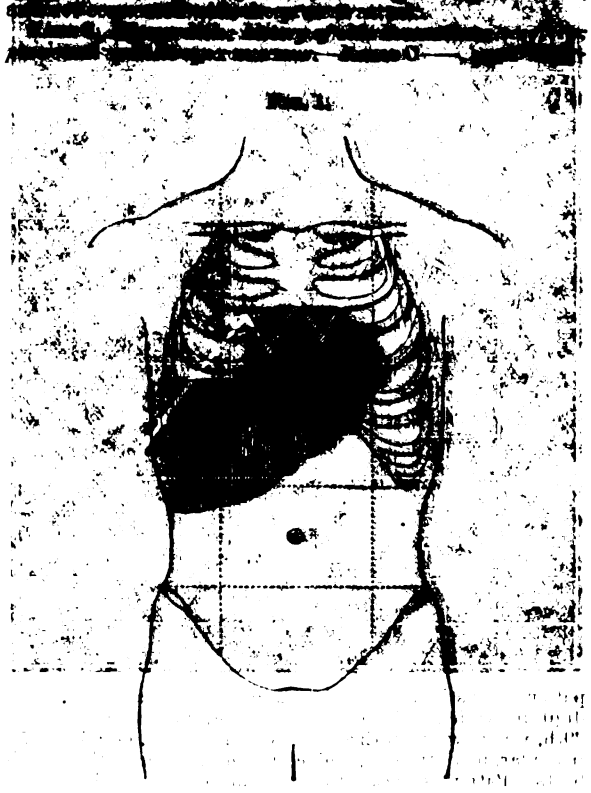
On post-mortem examination the pericardium contained a small amount of serous fluid; the right and left ventricles were considerably dilated. There was a little lymph upon the pericardium, but a good deal of sub-pericardial ecchymosis. The cavities contained a considerable amount of firm decolourised clot, which was probably forming for some time before death; this was adherent in the right auricular appendix. The left ventricle was much dilated; the valves healthy. The pulmonary arteries contained in their larger branches clots, probably post mortem, but further on they were obstructed by what might have been emboli. The walls of the heart below the endocardium looked uniformly pale and streaky to some depth, and in the substance of the muscular tissues were numerous large patches. The spot at which this appearance was most marked was about the junction of the upper with the middle third of the left ventricle. At this point the heart appeared bulging, and approached nearest to the surface, corresponding closely with the spot at which the pulsation of the apparent apex was described above. The spleen was considerably enlarged. The knee-joints, which were still somewhat swollen, contained a good deal of golden-coloured, rather viscid, and somewhat turbid fluid, but beyond a slight vascularity of the synovial fringes there was nothing further abnormal. Microscopical examination showed that in these white patches in the heart the muscular tissue had undergone acute granular (fatty) degeneration, its fibres being converted into granular cylinders. There was no intestinal growth.

This case, again, is complete, and the necropsy demonstrated the very advanced changes in the muscular tissue of the heart, and explained fully the clinical condition of the patient.

In the next case the patient also died, but no post-mortem was permitted.

CASE 4. *Probable myocarditis; death; no necropsy.*—I saw the patient in consultation with Dr. Rosser of Croydon. The account of the case is taken from the brief notes which I made at the time. Mr. C——, aged thirty-six, almost immediately after his return from a short visit to the Continent, was seized with pains in the joints, which Dr. Rosser thought to be probably due to rheumatic fever, and ordered

Digitized by Google

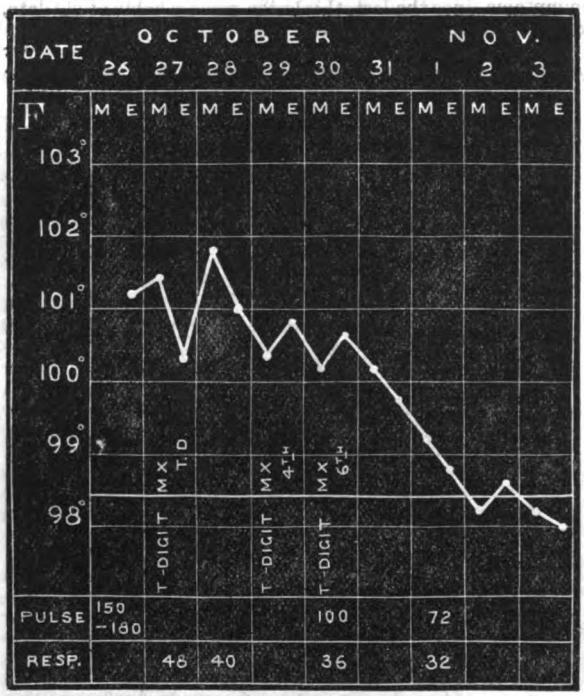


him to lie up at home. There was no history of any previous illness, and the patient had been in his usual health the only change from his usual condition being that he had gained flesh rather rapidly during the last two years. From the commencement of October, when the attack came on, until October 16th, the joint pains had continued, though they were not severe, and the temperature remained about 101° or 102°. On the 16th the respiration became rapid (40), and the patient complained of shortness of breath; the pulse was 140 and ill-sustained. I saw the patient on October 18th. He sat propped up in bed, being unable to lie down from shortness of breath. The respiration was panting and laboured; the complexion somewhat dusky; the pulse rapid and small. The lungs were congested; the heart-sounds extremely feeble, but the apex-beat could not be felt nor the cardiac dulness determined on account of the obesity of the patient. No murmur or friction was audible. The temperature was 102°. There was slight general œdema, but no albumen in the urine. The patient was much troubled with flatulence, and his appetite was poor. It was clear that the heart was the organ chiefly in fault, and stimulants and digitalis were ordered. On October 21st the patient seemed a little better, and the œdema was less; but he had been slightly delirious at night, and seemed a little wandering, even in the daytime, when I saw him. On the 22nd the delirium had increased, and the patient was more feeble. The same treatment was pursued; but the weakness increased, and with it the delirium. He gradually sank, and died the next day. No post-mortem examination could be obtained, so that absolute demonstration of the cause of the illness is not forthcoming; but I consider that I was justified, from the clinical evidence, in referring the case also to the same group as those preceding—viz., the group of acute myocarditis.

The next case was developed in the course of rheumatic fever, the patient, however, recovering completely. It was published in the St. Bartholomew's Hospital Reports for 1878, in an article on Rheumatic Fever.

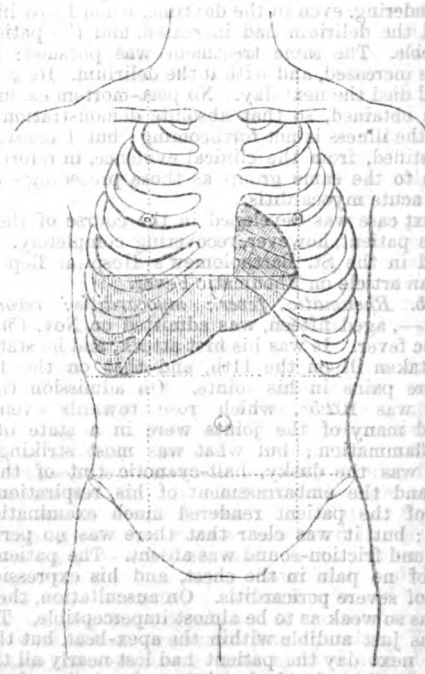
CASE 5. *Rheumatic fever; myocarditis; recovery.* — John H——, aged fifteen, was admitted on Nov. 15th, with rheumatic fever. It was his first attack, and he stated that he was taken ill on the 11th, and that on the 12th he had severe pains in his joints. On admission the temperature was 102·5°, which rose towards evening to 103°, and many of the joints were in a state of rheumatic inflammation; but what was most striking about the case was the dusky, half-cyanotic tint of the complexion and the embarrassment of his respiration. The distress of the patient rendered much examination undesirable; but it was clear that there was no pericardial effusion, and friction-sound was absent. The patient complained of no pain in the chest, and his expression was not that of severe pericarditis. On auscultation, the heart-sound was so weak as to be almost imperceptible. The first sound was just audible within the apex-beat, but that was all. The next day the patient had lost nearly all the pain in his joints; but the dusky tint persisted, though perhaps it was not quite so marked, and the heart-sounds began to be more audible. No friction; no murmur. Temperature 101°; pulse 96, dicrotous; respiration 30. — Nov. 17th: No pains; temperature 98·6°; cardiac dulness slightly increased upwards and to the left; no friction; slight amount of albumen in the urine.—18th: The patient looks more dusky and pinched; is very drowsy; has no pains, but has been sick several times during the last twenty-four hours, especially after food. Cardiac dulness increased towards the right, reaching to the right edge of the sternum; apex not to be felt; heart-sounds very feeble, as yesterday; temperature 99°; pulse 84, very dicrotous. As it was thought some of the sickness might be due to the salicylate of soda which he was taking, it was stopped.—19th: Better; pulse 76, dicrotous; heart-sounds very feeble, especially the first apex-sound; no friction; no murmur; no albumen in the urine. The patient now commenced gradually to improve. — On the 26th this note was taken: Heart very feeble, at the apex first sound weak, second prolonged; no murmur; deep cardiac dulness increased slightly upwards, but more considerably towards the right.—29th: Cardiac dulness less than on the 26th; sounds still very feeble, but stronger than they were; faint systolic murmur within the apex, loudest at the left base over the pulmonary valves, at the base the sounds were hardly audible at all. From this time the heart gradually recovered itself, but convalescence was interrupted by a short relapse, and subsequently by slight pleurisy at the right base behind. When the patient was discharged at the end of December the cardiac dulness was normal, and there were no traces of cardiac lesion.

This case was by far the most serious of the forty cases referred to in the paper quoted as regards the general condition of the patient during the acute attack, so much so that on November 18th his state was such as to cause very grave anxiety. It was evident that he was suffering from some affection of the heart, but it was also clear that it was not pericardial, and equally clear that it was not endocardial. The only conclusion to be drawn, therefore, was that it was myocardial. It is often stated that it is doubtful whether recovery has ever taken place after myocarditis. This of course refers to general myocarditis, for the scars found not unfrequently in the muscular tissue of hearts post mortem are sufficient evidence that partial myocarditis is not by any means necessarily fatal. If the interpretation of the above case is correct, and it is difficult to see what other will account for the symptoms, an additional interest is given to it from this fact.



The next (sixth) case differs from those described only in the fact that a faint systolic apex murmur was left after the patient's recovery; but inasmuch as prior to this illness there had been three attacks of rheumatic fever, with cardiac symptoms since the last, this lesion was probably of old date,

On admission.



four, knife-grinder, was admitted into the Royal Free Hospital on Oct. 26th, 1883, with cyanosis and dyspnœa. When four years old he had his first attack of rheumatic fever. The date of the second attack is uncertain, but the third occurred at the age of thirty-seven. For three years before this, and ever since, he had been troubled with dyspnœa, palpitation, and pain in the cardiac region on exertion, and for the last three years had suffered from winter cough and cold hands and feet; recently he had been losing flesh. His present illness had been coming on gradually. The patient was a spare, thin man; the face and body were cold to the touch; skin dusky and mottled; the mottling being most marked on the lower extremities, where it formed round the ankles livid patches, and upon the legs small circular but not petechial spots. Except for slight general bronchitis the lungs were healthy, but the respiration was chiefly abdominal. The impulse of the heart was felt in the fifth intercostal space, slightly outside the nipple, but was not visible. The area of cardiac dulness (see Fig. 1) was

increased upwards and outwards, and reached a little way beyond the right border of the sternum. The heart was beating very rapidly, about 188 in the minute. The sounds were short, sharp, and faint, like the ticking of a chronometer, this peculiarity being most marked just to the left of the sternum. No distinct friction or murmur was audible. The radial pulse was very weak and fluttering; it was difficult to count, but was about 150 in the minute, showing a loss of thirty to forty beats as compared with the heart. The abdomen was resistant, and the liver was enlarged downwards, reaching to about two and a half to three inches below the ribs. The tongue was clean and moist, the bowels regular, and the appetite bad. The urine was alkaline, sp. gr. 1022, and contained some albumen. Temperature 101·4°. The patient was excitable, restless, and somewhat delirious. He was given ten minims of tincture of digitalis and ten grains of bromide of potassium every four hours, with light food and some brandy.—Oct. 31st: The condition was much the same; there was the same panting dyspnœa, but the cough seemed more troublesome. The expectoration was scanty and viscid. The temperature, which had been gradually falling, was to-day 99·8°; the pulse 80, irregular, but much stronger, as were also the heart-sounds; respiration 36 and shallow as hitherto. The food was taken better, but the

patient was still very restless and delirious at night. The digitalis, which had been reduced to every six hours on the 29th, was now given three times a day.—Nov. 1st: Pulse 72, irregular, but stronger, and equal in number to the heart's beats. Patient somewhat drowsy, but on the whole less delirious. A soft blowing systolic murmur was heard to-day at the apex for the first time.—2nd: Drowsiness and restlessness continue, and to-day there has been some twitching of the arms and legs. Breathing still difficult and panting, but the heart's action is steadier, slower, and stronger. Pulse 76, irregular, like the heart, but of good volume and more power. The patient complained to-day of "feeling very bad."—5th: The drowsiness has continued during the last three days, but the delirium has given place to slight wandering only at night-time. The heart and pulse beats, which were still irregular, were now much slower, the latter varying from 48 to 56 only in the minute. The albumen had quite disappeared from the urine. The digitalis and bromide of potassium, which had been on the 3rd increased again to every six hours instead of three times a day, was now stopped entirely, and a mixture of solution of strychnia (fifteen minims) with ether and ammonia substituted with great advantage; for the pulse rose to 60 next day, and in the following days continued to rise to 70 and 76; but though the drowsiness became less, there was more delirium, especially at night, due no doubt to the giving up of the bromide. The temperature, which fell on the 2nd to normal, did not rise again during the illness. (See chart.)—13th: Systolic apex murmur well marked. Patient began to take solid food with enjoyment, and the brandy was reduced from 6 oz. to 3 oz.—15th: The liver had returned almost to its normal dimensions, and the cardiac dulness was much reduced. The improvement was steady, and with increase of strength the loudness of the murmur increased.—22nd: The medicine was altered to perchloride of iron and strychnia, with ether and chloroform. — Dec. 3rd: The cardiac dulness could hardly be detected to the right of the sternum, and the systolic murmur, though distinct at the apex, could not be heard far into the axilla, and was hardly audible at all behind. The patient was now allowed to sit up for a short time; but, as this seemed to cause some breathlessness, he was kept in bed again, but on the 21st he was able to be up without discomfort. Pulse 116 while standing.—31st: The patient could walk about without discomfort. The cardiac dulness, though still increased, was much smaller than before, and the apex murmur could not be heard. This, however, varied. On some days it seemed absent, and on others it could be heard, but never more than faintly.—

FIG. 2.

On discharge.

Jan. 5th: The patient was discharged at his urgent request but on the 15th he returned, finding himself not strong enough for work, which he had tried to do and failed. The condition of the heart on the 16th was as follows: Apex under nipple in fifth space, the cardiac dulness a little increased upwards and outwards, but not reaching beyond the left edge of the sternum. (See Fig. 2.) Systolic apex murmur heard faintly immediately over apex beat and nowhere else. This murmur varied in intensity from day to day, but was never loud, and could at no time be heard anywhere except in the immediate neighbourhood of the apex beat. The patient rapidly gained strength, and left the hospital fairly well.

The next case differs from all the rest in the fact that the myocardial symptoms were associated with evidence of fresh endocardial and pericardial mischief. This case forms a link between the rarer primary myocardial inflammation and those more common forms secondary to or associated with lesions of other parts of the heart substance.

(To be concluded.)

A POLISH surgeon, Dr. Roman Oswald, who went to the Servio-Bulgarian war to render professional assistance, was shot in the battle of Slivniza, the wound necessitating amputation of the leg.

ON

TREPHINING IN EPILEPSY RESULTING FROM OLD FRACTURE OF THE SKULL.

BY HENRY E. CLARK, F.F.P.S. GLASG., M.R.C.S.,
SURGEON TO THE GLASGOW ROYAL INFIRMARY.

THE case of traumatic epilepsy recorded by Mr. Holmes in THE LANCET of September 5th, 1885, recalls to my memory a somewhat similar case under my own care, the details of which may be of interest as a contribution to a rather difficult subject. As the result is much more favourable than in Mr. Holmes's case, and two years having now elapsed since the operation, my communication may serve to correct a little the unfavourable impression which his note undoubtedly leaves.

J. M'L——, a boy twelve years of age, a native of Campbelltown, first came under my notice in July, 1883, having been sent to me by Dr. Middleton. Between five and six years before he had received an injury to his head, and there was at this time present a depressed cicatrix over the right frontal eminence, evidently the consequence of a fracture of the skull. About six months before I saw him he began to have epileptic fits; these at first were infrequent and mild, but had latterly increased in number and severity. He was put on small doses of bromide of potassium combined with borax, and was kept on this treatment for about eight weeks, but with little or no improvement; he therefore became an inmate of ward 16 in the Glasgow Royal Infirmary on September 22nd, 1883. We were now able to observe him closely, and were satisfied that the fits were essentially epileptic. The boy always became completely insensible, the convulsive movements were general, and it was impossible to make out that either side of the body was more affected than the other; there was no foaming at the mouth, but the characteristic pallor was well marked. On the day following his admission he had a fit while I was in the act of examining him, and at the instant I made pressure on the cicatrix, but on no subsequent occasion were we able to produce the same result by this means. There could scarcely be said to be a distinct aura preceding the fit, but after he had been under observation for about six weeks he stated that before the fit came on he felt some pain in the cicatrix; we rather suspected that this statement was made to satisfy our oft-repeated inquiries. The mental state was not quite satisfactory; he could not be said to be idiotic, but he was clearly not so sharp as a boy of his age should be. In the ward he was regarded as "not all there." From the time of his admission a record of the number of fits was kept, and for about a month his temperature was taken night and morning. It is unnecessary that I should give the latter particulars, as there was no distinct deviation from the normal, but the statement of the number of fits each day during the month of October will be useful for comparing with the state after operation, and I therefore append it:—

Total number of fits, 92.

Before admission the patient had on more than one occasion bitten his tongue when in a fit, and while under observation in the hospital he twice created some stir in the ward by being seized with a fit while eating, a morsel of bread getting into his air-passages, which was only dislodged by the house-surgeon promptly inverting him and thumping him on the back. I have no reason to doubt that in the latter instances he ran serious risks of suffocation, and this circumstance had some weight with us in deciding upon operating. Although he was taken into the hospital with a view to trephining being performed, there was so little to indicate any localised lesion of the brain, so slight a reference of the origin of the fit to the site of the injury, and so long a time had elapsed between the injury and the commencement of the seizures, that I had much difficulty in making up my mind to perform the operation. However, after he had been nearly two months an inmate of the ward, it was finally decided that the experiment of trephining should be tried.

The operation was performed on Nov. 14th with antiseptic precautions (including the spray). A crucial incision was made down to the bone at the site of the old injury, and the flaps and the periosteum being turned back, a medium-sized trephine was applied and a disc of bone removed. There was not found to be any spicule or rough edge of bone projecting inwards, and the dura mater was perfectly healthy and its pulsation normal; but there was found to be general thickening of the frontal bone at the part where the trephine was applied, the bone measuring fully three-eighths of an inch in thickness, which is certainly excessive for a boy of that age. The circle of bone removed was reinstated after its inner edge had been bevelled off, so as to prevent its pressing on the dura mater; a notch was also cut on the side of it to serve for drainage, and a few pieces of carbolised catgut were inserted to act as a drain. The flaps were then brought together with catgut stitches, and the wound dressed with carbolic gauze.

The next morning, when I saw him, he was sitting up in bed, and the nurse reported that she had difficulty in preventing him from getting up and playing with the other boys. There had been no rise of temperature, nor was there any throughout the further progress of the case. The wound was dressed antiseptically on Nov. 17th (three days after the operation), then on the 24th, and lastly on the 28th, after which, the wound being now superficial, it was dressed with boracic lint alone. The restored circle of bone did not necrose, as we thought might possibly be the case, but united satisfactorily to the part whence it had been taken. The operation therefore caused the least possible disturbance, and the integrity of the skull was only temporarily interfered with. The point of special interest, however, was the effect on the fits. These did not cease, as we had hoped might be the case, but they were materially diminished in number and were much less severe; the insensibility was now incomplete, the convulsive seizure much less marked and shorter in duration, and, as is shown by the following table, free days alternated with those on which the attacks took place:—

Date.	No. of fits.	Date.	No. of fits.

Total number of fits, 33

From this time the seizures became much less frequent, and when dismissed from the ward on Jan. 12th, 1884, he had not had a fit for a week. Since his dismissal he has been under the observation of Dr. M'Neilage of Campbelltown, who writes to me under date of Sept. 11th, 1885: "The lad, J. M'L——, has just been here to report himself, at my request. For sixteen months prior to April of this year, covering the whole period since his discharge from hospital, and up till April, he was perfectly free from epileptic fits. His mother states that four times since then he has had slight attacks in bed, generally early in the morning; she attributes these attacks to over-indulgence in sweets, and

Digitized by Google

has a suspicion that he suffers from worms. She states that the attacks were slight, and that he did not seem to be hazy mentally after them, and that, whereas he was formerly childish, his mind is now quite vigorous. His general health is very good, and his condition mentally and physically much improved."

Remarks.—Trephining for epilepsy is by no means a novel operation, having been practised many times in the early part of the present century, and even dating as far back as the middle of the seventeenth century. Echeverria, in two admirable papers in the *Archives Générales de Médecine* for 1878, collects 145 cases where the trephine was used for the relief of epilepsy, and I have been able to collect about fifty more. In a very large number of these the lesion was a gross one, being either a compound fracture of the skull with large or deep depression, an extensive syphilitic caries, or a tumour connected with the dura mater. The case just detailed differs from these in the apparently slight change which had taken place at the site of the old fracture, nothing but a general thickening and slight condensation of the bone having been found. In this respect, however, my case is not singular, for in a patient operated on by W. Parker, an American surgeon, there was nothing found but abnormal thickening and density of the bone, yet as the result of the operation the symptoms passed off, and at last report, two years after the operation, the patient was well. A similar case is reported by Brainard of Chicago, another cited by Russell, and a third as far back as 1771 by La Motte; while in recent years parallel cases have been detailed in full by West of Birmingham, Bellamy and Lees of London, and one or two have occurred in the practice of my colleagues. The long period which elapsed between the injury and the onset of the disease led to a little doubt in our minds as to whether the injury and the disease stood in the relation to each other of cause and effect; yet we find the interval is small compared with what it was in one of Echeverria's cases, where the fracture of the skull took place in infancy, and the epilepsy did not show itself till the patient was eighteen years old.

It should not be forgotten that cases of traumatic epilepsy invariably tend to grow worse, and are little, if at all, affected by medical treatment; they are most commonly accompanied by distinct enfeeblement of the intellect. In this lad, this amounted only to his being regarded as "not all there," but in not a few patients it develops into some definite form of insanity. Echeverria dogmatically asserts: "Once declared, traumatic epilepsy caused by injury to the head leads to early insanity or to feebleness of intellect.[1]

The question of localisation unfortunately did not come into my case. The injury being in the frontal region and not implicating the motor area of the brain, we could not expect any distinct localisation of the convulsive seizures; but this formed one of the difficulties in the way of deciding upon operation, and we were equally in want of a definite aura, or the existence of pain in the cicatrix. It is true that he did sometimes tell us that he felt pain in the old wound just before the fit came on; but he had been asked the question more than a dozen times before the symptom appeared, and we had a strong suspicion that he fitted this manifestation to our wishes.

The cure was not immediately effected, and indeed we were rather disappointed with the small improvement that was at first apparent. Contrasting, as our case did, in this respect with such remarkable cures as that of Cline, where the patient had his last epileptic fit on the operating table immediately before the disc of bone was raised, this disappointment was natural; but it is noticeable that in similar cases where there was a gross lesion, such as a large depression of bone, a projecting spicule, or a clot, the relief was immediate; but in those which showed simply chronic thickening and induration of the bone the seizures continued for some time after the operation, but were less frequent and much milder. We were satisfied that although we had so far gained that the fits only occurred on alternate days, there was the irritation of the wound to be considered in accounting for their continuance, and, what was perhaps of more importance, the brain had got into a "habit" of periodic explosions, which took place almost automatically, and it was extremely difficult to break through this and upset its automatism. As the wound healed the fits became less in number and degree, and in about two months ceased altogether.

It may be asked in what way did the operation benefit the patient, seeing that no gross lesion was found? Now, I think we are too ready to believe that injuries of the brain may take place, depressions of bone press upon it, or thickened bone prevent its due expansion, and yet the individual be none the worse mentally or physically. It is true that many persons have performed all the duties of life in a fairly satisfactory manner after serious head injuries, and have lived for years in the enjoyment of good health with depression of one of the bones of the skull to the depth of half an inch or more; but I am satisfied that in all these cases, if a searching inquiry had been made, it would be found that there remained as the result of the accident enfeeblement of memory, loss of the power of application to study, or perhaps an inability to perform certain muscular acts, or at least to perform them with the same ease as before. Every accident of this nature, I believe, leaves its mark upon the brain, and, to my mind, the general hypertrophy of the frontal bone at and about the seat of fracture in this case was quite sufficient to account for the epilepsy. By removing a disc of bone the pressure on the brain at the part was taken off, and when reinstated the disc had been thinned so as not to press on the dura mater, but allow of free expansion of the brain. In more than one recorded case a depressed and neuralgic cicatrix served as the exciting point of epileptic seizures, without there being any thickening of the bone or dura mater; but I was satisfied that the cicatrix in this case was not the starting-point of the attacks.

One interesting detail in the operation deserves more than a passing notice—namely, the mode of dealing with the disc of bone removed by the trephine. It has been so much the custom to throw away this piece of bone that in my search through the literature of the subject the only cases in which mention is made of the re-implantation of the disc are those of my colleague, Dr. Macewen. As Dr. G. H. B. Macleod also informs me that he practised it on one occasion during last year, it is probable that other instances are not wanting; but I think I am safe in assuming that it has not been very generally done. In my patient it was most successful; the bone joined again as easily as if it had been a simple fracture, and the boy's skull is as complete as ever it was. That this is a decided gain over the condition so common after trephining—where an opening is left, covered indeed by a membrane, but often this covering is so thin that the pulsations of the brain can be felt or even seen—no one will probably be found to dispute, especially as the ordinary conditions of such openings is a source of possible danger to the patient throughout life. Putting aside, therefore, the value of this communication in its relation to the treatment of epilepsy, it has not been written in vain if it directs attention to the possibility of returning the bone removed by the trephine, and satisfies anyone that this is a safe and reasonable proceeding.

ON THE SYNTHESIS OF URIC ACID.

By P. W. LATHAM, M.A., M.D., F.R.C.P.,

DOWNING PROFESSOR OF MEDICINE, CAMBRIDGE; SENIOR PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

By adopting the following method I have succeeded in producing uric acid in the manner indicated by Horbaczewski. The precise details are here given, and the process can be very easily and successfully repeated.

I took thirty grains of glycocine and three hundred of urea, and put them into an ordinary test-tube (6 in. by ¾ in.). Having inserted a thermometer, to note the exact temperature, the test-tube was then placed in an oil bath, the temperature of which had been previously raised to 230° C. The bath was maintained at this temperature, and the heat so arranged that the bath could be raised in a few seconds to 240°. The mixture of glycocine and urea quickly melts; at 110° it begins to boil, and ammonia is given off; as the temperature rises it begins to froth up, and between 175° and 180° does so to a considerable extent. By raising the test-tube from the bath from time to time this action can be controlled, and the temperature kept at 180° for some minutes, until the ammonia comes off much less freely, and the mixture acquires a very faint yellowish tinge. The heat of the bath must then be rapidly raised to 240° and the temperature of the mixture

Digitized by Google

in the test-tube quickly raised to 210°. By lifting the tube from time to time out of the bath the temperature must be kept exactly between 210° and 212° for five minutes, when the mixture will acquire the colour of brown sherry, but remains perfectly clear. The test-tube can now be removed from the bath and allowed to cool, when the mass will assume a very pale fawn colour. The mass can now be almost dissolved in three ounces of warm water, and perfect solution takes place on the addition of solution of potash. The fluid is then supersaturated with ammonium chloride, and a considerable excess of ammonia added, otherwise a mixture of urate and cyanurate of potash may be precipitated. A mixture of two fluid drachms of the solution of ammonio-nitrate of silver of the British Pharmacopœia, the same quantity of the solution of ammonio-sulphate of magnesia and of strong solution of ammonia, is now added to the other liquid. A considerable brownish precipitate of the mixed urate and cyanurate of silver is thrown down. Let this stand for twenty-four hours and allow the precipitate to subside. Decant off the supernatant liquid, and wash the precipitate with water, to which a little ammonia has been added. Take now two parts of solution of potash, and, having saturated one part with sulphuretted hydrogen, mix it with the other part. Add sufficient of this solution to decompose the argentic precipitate, heat the mixture gently, and filter from the insoluble sulphide. To the filtrate add sufficient hydrochloric acid to produce a slight but distinctly acid reaction. Boil the mixture until all the sulphuretted hydrogen is driven off, and, on cooling, uric acid mixed more or less with cyanuric acid, with very little colouring matter will be deposited. Pour off the mother liquid and evaporate it down, when a further amount of uric acid may be obtained. The presence of uric acid at this stage is shown very distinctly by the murexide test. In the earlier stages the murexide reaction is very faint indeed. To separate the uric acid from the cyanuric, the crystals must again be dissolved in a little solution of potash, this supersaturated with ammonium chloride and ammonia, and the uric acid separated from the cyanuric by means of the ammoniacal solution of silver and magnesia, and the precipitated argentic urate treated as before. In this way, though the yield is comparatively very small, I have obtained extremely well marked crystals presenting all the characteristics when seen under the microscope of ordinary uric acid, and responding perfectly to the murexide test. Horbaczewski's first paper appeared in the *Berichte* for November, 1882, in which he directed the glycocine and urea to be heated to a temperature of 200° to 230° C. I tried the experiment then, but failed—owing, I now believe, to the temperature used being too high or too low. A second paper by the same author appeared in the *Monatshefte für Chemie* last May, giving further details, but simply directing the substances to be heated in a test-tube over a Bunsen's burner until the fused mass becomes opaque. This induced me again to try the experiment, and I am glad to be able to confirm the statement that uric acid can be produced in this fashion. Why I adopted a temperature of 210° to 212° C. in the experiment, and the bearing this synthesis has on the formation of uric acid in the animal body, I shall endeavour to explain in my lectures at the College of Physicians at the end of next month.

Cambridge.

ON THE

EFFECTS OF TOTAL AND OF PARTIAL DESTRUCTION OF THE SUPRA-RENAL BODIES.

BY T. CHURTON, M.D.,

PHYSICIAN TO THE LEEDS INFIRMARY, ETC.

THAT any disease which produces the essential or pathognomonic signs of Addison's disease must be capable of first entirely, or almost entirely, destroying the adrenals, seems a proposition likely to be established. Neither partial atrophy nor partial destruction by new growths appears to be able to cause obvious, or even perhaps clearly recognisable, symptoms and signs. A single case, however, of Addison's disease, or of symptoms practically undistinguishable from the group known by that name, without any disease of the adrenals, on the one hand; or a single case of entire or almost entire destruction of the adrenals, in which the symptoms of Addison's disease had been "observed not to exist," on the other hand,—would of course be fatal to the theory. It is said that these organs quite normally undergo atrophy in old people; but I wonder whether Professor Humphry would admit that. It seems possible, however, that if such atrophy be not quite normal in old people, the symptoms due to it might be in many cases less marked, as are the symptoms of some other diseases in them, so that even when present they may often escape notice. I shall return to this latter point. The first case to be now mentioned is a typical one according to the old view: complete caseation of both organs, and apparent absence of all other disease.

F. B——, aged nineteen, a farm labourer, of middle height, but spare build, dark-brown hair, brown eyes, and having several decayed teeth, was admitted into the Leeds Infirmary on Sept. 8th, 1884. He complained of weakness, giddiness, constipation, short cough with some expectoration, and loss of colour. He had not felt well for four months. His illness began with anorexia, obstinate constipation, gradually increasing pallor, and dizziness. He could not account for the illness. Nothing unusual had happened to him, except that at his work he was, of course, much exposed to the weather, and "one day he caught a cold" bad enough to remember; he had never been well since. His house and district were healthy. His family history, imperfectly known, furnished no clue. He had had no other illness since childhood. On examination, nothing remarkable was found in any of the chief organs. He seemed, however, strangely dull, slow and apathetic; and it was noticeable that his skin was somewhat dark and bronzed in many places; and several small, deep-brown, almost black, sharply defined spots were visible on his face and neck. He said that these freckles had appeared since his illness began, and that their number was increasing. Temperature 99° and 100°. He had lost flesh. In the absence of signs of disease in other organs, a diagnosis of disease of the adrenals was made. On Sept. 27th, upon trying to get up and dress, the patient felt sick and prostrate; thenceforward he lay in bed. On Oct. 9th, at 3 A.M., he was found out of bed in a semi-maniacal condition, but the nurse was at length able to persuade him to go back to bed, where he lay quietly, except for occasional muttering, until 9 A.M. He then became completely maniacal—writhing, shouting, striking at persons near him, &c. After taking twenty minims of laudanum in an ounce of wine he became quiet in a short time, and remained so all day. During the attack the pulse was observed by Mr. Morris, the junior house-physician, to be quiet and feeble, and the respiration unaltered. Next morning, at about 8 o'clock, he again became maniacal; and as the opium and wine seemed then to have less effect, a dose of bromide of potassium with hydrate of chloral was given. He became quiet, but died in the evening. The adrenals were the only organs in which disease was found. Dr. Griffith, resident medical officer, gives the following account of the necropsy: "Body rather poorly nourished. Skin earthy-looking. Axillæ dark in colour. Many small dark spots on the skin, found on microscopic examination to be caused by increase of pigment in the rete Malpighii. Brain apparently normal. Much congestion and œdema of lower part of lungs; evidence of old pleurisy. Heart small; weight, 6½ oz.; right auricle contained large pale clot, passing into ventricle and pulmonary artery. The kidneys, liver, and spleen were normal to naked-eye examination, but on microscopic examination the small arteries and capillaries were found to contain an unusually large number of blood-cells. The supra-renal capsules were evenly and markedly enlarged, being each of them 2½ in. in width, 2 in. in length, 1 in. in thickness, and 1 oz. in weight. The cut surface, smooth and hard, had a white and rather cartilaginous appearance, with yellow patches interspersed—sections of caseating nodules. Microscopically, the greater part of them was found to consist of a small-celled growth with very numerous giant cells; the usual granular débris was found in those parts undergoing caseation. Many of the smaller arteries were affected with obliterative inflammation of the inner coat. No bacilli could be found. The semilunar ganglia appeared normal. There was no matting of the tissues around the adrenals, and no disease of neighbouring structures."

In the following cases I have recently observed at the infirmary more or less disease of the capsules has been

Digitized by Google

found which had not caused any recognised symptoms during life.

CASE 1.—Male, aged twenty-four. Strumous disease of wrist; amputation. Death from pulmonary phthisis. Ulcers in both small and large intestines. Each adrenal contained four or five caseous nodules larger than peas. Nothing remarkable in other organs.

CASE 2.—Female, aged forty-five. Cut throat. Mania came on two days after self-inflicted wound; exhaustion. Kidneys slightly granular. Spleen remarkably small. Œsophagus very thick. Small intramural uterine myoma. Right adrenal contained a cyst as large as a nut.

CASE 3.—Male, aged seventy-four. Death from hernia. Caseous growths in one testis, both epididymes, mesenteric glands, spleen, liver, kidneys, and in adrenals. Both adrenals were much thickened throughout by the caseous growth, but were not enlarged in other dimensions.

CASE 4.—Male, aged twenty-nine. Dropsy of cerebral ventricles, including fourth. Right adrenal contained blood. (About three years ago I saw a case of hæmorrhage into both capsules in a boy who died from a severe burn.)

CASE 5.—Female, aged forty-two, but looked older. Atheroma of vessels. Granular kidney. One adrenal contained nodules; giant cells were found in these. Nothing of the kind in other organs.

The adrenals are described in my notes as being soft and very friable in a woman aged forty-five, who had died of cancer of the peritoneum; and in a man aged thirty-four, who had died of septicæmia after excision of knee. They were thin and shrivelled in the case of a man aged fifty-three, who died of phthisis, and in a man aged forty-five, who died of pneumonia. And in many other examinations of old, of middle-aged, and even of young persons who died of various diseases, I have noticed that the adrenals were very thin walled, and either hollow or having easily separable sides. This is a very common condition. In the case of a woman aged sixty-nine, however, who died, not from disease, but from an accident, the adrenals showed no such wasting, but were as large in every dimension, and microscopically of as perfect structure as in young subjects. Nor could even this person be accepted as a specimen of healthy old age, since her kidneys were markedly granular.

In none of the cases briefly described above in which abnormality existed had any symptoms or signs been observed during life—in none of them, probably, were any looked for—indicating disease of the capsules. For my own part, I have not until recently thought of examining elderly patients for symptoms of Addison's disease, although it is not unusual to perceive a change in the complexion and in the colour of the skin of the arms and legs of old persons. But a short time ago I happened to observe that the hands of a gentleman aged seventy-two, occasionally seen by me in consultation, were as brown as those of anyone long exposed to the sun, although he very rarely left the house. On further investigation his elbows and abdomen were found to be distinctly brown, and the areolæ of the nipples very dark; and he voluntarily pointed out the change of colour in the abdomen and a large number of light-brown freckles which had recently appeared there. He has had an unusually weak stomach all his life, and during the last year or two has suffered from debility, nausea, sinkings at the epigastrium, small ulcers on the tongue, and periods of great depression; indeed, he never at any time feels any desire for exertion of mind or body, though his intellect and senses when roused do not seem to be much impaired, and he has no stiffness or special want of power in his limbs. Both his regular medical attendant and myself had been urging him to try change of air and scene, inasmuch as hitherto we had discovered no organic disease; but I have now become somewhat more cautious as to the language and arguments with which I encounter his decided opposition to the course we recommend; for it seems possible that his adrenals are atrophied; and the case of the woman of sixty-nine, whose adrenals were demonstrably perfect in size and structure, has made me doubt whether it is really normal for these organs to become atrophied in old age. The observations which have led to the opinion that such normal atrophy does occur may possibly have been made in hospital post-mortem rooms; but unless many old persons are brought there who have died shortly after accidents such an inference cannot be justified. I say many, for probably most of the street accidents of London and other large towns occur to persons who are not in good health, and who are in consequence less able to guard themselves against accident. Perhaps one might even venture to say that really healthy old people are not excessively numerous. It will, however, sometimes happen that a fairly sound man of over seventy years of age is killed: his are the organs to be investigated.

A NEW TREATMENT OF GONORRHŒA CHRONICA BY MEANS OF GROOVED BOUGIES.

BY LEOPOLD CASPER, M.D.,
PRACT. ARZT IN BERLIN.

THE extraordinary difficulty of healing some cases of chronic gonorrhœa is well known. There are men who have every morning an exudation, although they have tried every possible remedy against the evil. Frequently, especially after coitus, the chronic disease becomes acute, which often, more particularly in young married men, leads to disagreeable results. The difficulty of healing chronic gonorrhœa is to be sought less in the means used than in the way in which they are used. This will appear when we more closely consider the anatomy of the urethra and chronic gonorrhœa.

The male urethra is a tube from fifteen to eighteen centimetres long, which in its separate parts is constructed so differently that it appears unjust *a priori* to place a disease of one of these parts under the class named "gonorrhœa chronica." For the same reason that the cervix uteri is to be separated from the uterus, the pars spongiosa must be separated from the partes membranacea and prostatica. An inflammation of the pars spongiosa does not necessarily imply that the pars membranacea is also inflamed, or, *vice versâ*, that an inflammation has its seat in the membranous portion while the spongious part is normal. In fact, most cases of chronic gonorrhœa are located at the end of the bulbus, or at the juncture of the end of the bulbus to the pars membranacea. They begin as acute inflammation in the fossa navicularis and slowly extend to the bulbus. This will be clearly seen by the following:—Of 100 cases of callous stricture, about seventy occur in the bulbus, or at the place where the bulbus becomes the pars membranacea, twenty in the fossa navicularis, and ten in other parts of the pars spongiosa. Never does a callous strieture appear in the pars prostatica. The callous stricture being the result of gonorrhœa, the favourite seat of this disease will of course be the above-mentioned places, where strictures mostly occur. Although, as regards the pars cavernosa, the abundance of cavernous tissue will favour hypertrophy of the stricture-producing tissue in a higher degree than in the partes membranacea and prostatica still there would be more strictures in the posterior half of the pars membranacea and in the prostatic part, if all chronic gonorrhœæ were to extend to the bladder. Of course the inflammation sometimes extends to the posterior part of the urethra, but this is not a rule. In this respect the acute and chronic gonorrhœæ resemble each other. Rarely does the inflammation extend to the bladder in acute cases, whereas this frequently happens in chronic cases. Thus we speak of a "gonorrhœa anterior" when the inflammation does not pass the bulbus; if it extends further we call it "gonorrhœa anterior et posterior"; if the disease disappears before the bulbus and remains located in the posterior part of the urethra, we call it "gonorrhœa posterior." The bulbus is therefore a boundary in respect to the pathology of gonorrhœa. This will appear more comprehensible when we consider that the bulbus is also a boundary in an anatomical respect. The lamina media fasciæ perinei (Dittel) or the fascia perinei propria (Hyrtl), the important boundary between those organs which lie within the pelvis and those which lie outside of it, is closely connected with the bulbus. In front of this membrane is the pars cavernosa of the urethra, with the musculus transversus perinei superficialis and the musculi bulbo-ischiocavernosi; behind it is the membranous and the prostatic portion, with the glandes Cowperi, the prostata, and the important musculus constrictor urethræ, also called "compressor partis membranaceæ urethræ." This muscle is composed of two bundles, of which the upper lies above and the lower under the pars membranacea; both join at the median line, together with the same muscles coming from the opposite

Digitized by Google

side, so as to form a broad muscular ring to compress the urethra.

The importance of the bulbus as a boundary of the anterior and posterior urethra is apparent when we consider the treatment of gonorrhœa as hitherto practised—viz., injections by means of syringes. This method is suitable for most cases, but not for all, for the fluid injected into the urethra does not pass the bulbus without the use of force which no one would care to employ. If an injection is made slowly and with moderate pressure, the fluid extends to the front part of the urethra, and passes to the musculus compressor, but not beyond it; for, were this the case, the fluid would run through the posterior urethra into the bladder and remain there, whereas it is known that after a common injection the fluid comes back on removing the finger from the meatus. The in-going solution causes a reflex action of the musculus compressor, which results in a spasmodic closing of the urethra. The inefficiency of the usual syringes for treating gonorrhœa chronica posterior is therefore clear. At the same time we must remember that, if we wish to irrigate the posterior portion of the urethra, we must not push the catheter so far that its point touches the bladder; for in this case the catheter fills the urethra, and the injected fluid flows out again through the eye of the catheter without having touched the walls of the urethra.

Concluding from the foregoing that (1) all that which gathers before the musculus compressor in the urethra flows towards the orificium cutaneum, and that (2) a fluid gathered in the posterior part of the urethra runs into the bladder because of the inferiority of the musculus sphincter vesicæ internus as against the musculus compressor, we receive a hint as to the diagnosis between gonorrhœa anterior et posterior. If we see a drop on the orificium cutaneum, or that the lips stick together, or we find yellow spots in the washing, the gonorrhœa is surely seated at the bulbus, as all that which accumulates in front of the bulb flows towards the meatus. If these signs are absent the diagnosis is more difficult. The passing of a button-ended bougie causes in most cases only a slight burning and discomfort to the sound portions of the urethra, but when we touch a sore part the patient feels severe pain. If there is tenesmus, we have surely to deal with a gonorrhœa posterior; if tenesmus is present, if a drop appears on the orificium cutaneum, if the lips are glued together, or there is a spot in the washing, a gonorrhœa anterior et posterior is proved. On the other hand, if there is no tenesmus, we are not justified in the conclusion that there is no gonorrhœa chronica posterior. In acute gonorrhœa posterior tenesmus always appears; in chronic we often miss it.

The examination by means of the endoscope is always decisive, but the irritation which even the most careful introduction of this instrument will cause renders its application undesirable. Less painful and much more simple is the following proceeding. Tell the patient to hold his urine for five or six hours, and then to pass it into two glasses. If the first glass contains flakes or films, while the second glass remains clear, a gonorrhœa anterior may be diagnosed; should both glasses appear turbid, then a gonorrhœa posterior is present. To distinguish between gonorrhœa posterior and cystitis, which is likewise accompanied by turbid urine, is exceedingly easy; for, whereas in chronic posterior gonorrhœa the first portion of the urine passed is more turbid and contains more films than the second, in cystitis the reverse is the case. The reason of this is that the pus formed in the bladder will, according to the law of gravitation, sink to the fundus vesicæ, and will therefore only appear in the urine expelled last.

Considering now the pathology of gonorrhœa, it is known that the inflammation, as differing from urethritis, does not remain in the mucous membrane. Beginning in the mucous membrane, it continues into the submucous tissue, in the corpora cavernosa, and in the muscles. The product of the inflammation is an infiltration of the cells of the diseased parts. This infiltration gradually becomes fibrous tissue (Bindegewebe), which in its turn produces the cicatrix—the so-called "stricture." At the same time epithelial cells are formed, reaching to the surface of the mucous membrane and forming a thick epithelial stratum. The upper cells of this stratum, constantly sloughing, exfoliating, and mingling with the mucous secretion of the glands, constitute the crude pus which characterises chronic gonorrhœa. The glands and lacunæ of the urethra are also affected. From the fossa navicularis to the bulbus there are many lacunæ Morgagni, from eight to twelve millimetres long and half a millimetre wide, and several Littré's glands. The catarrh extends to both glands, and Dittel considers the well-known flakes or films and the goutte militaire as a product of the catarrh of Littré's glands and of the sinus Morgagni.

From this short review, it is clear that many chronic gonorrhœæ already represent the first stages of strictures, or, as Otis calls them, "large-sized strictures," which naturally cannot be cured by astringent solutions, or even such as are fatal to gonococci. If they are to be cured, local pressure must be used to remove the cell infiltration, while medical treatment is adopted to affect the catarrh. For these reasons treatment with bougies against chronic gonorrhœa has been mostly practised. Some went a step further and used bougies covered with simple salves; others, as Unna, employed bougies covered with a paste composed of butyrum cacao and different medicaments, which dissolves at body temperature. Similar considerations influenced me in the treatment of gonorrhœa chronica. But the usual bougies and the bougies covered with salves and paste not being successful in obstinate cases, I tried a modification. I was convinced that the paste bougies did not sufficiently fulfil their purpose, for very often the bougie does not reach the bladder, because the narrow walls of the urethra will not permit it to pass with the hardened paste; consequently one would have to wait, as Unna says, until the paste was dissolved, and then the melted salves would not reach the places behind the stricture where the catarrh is very often located, and for which they are intended. Further, cacao butter should not be allowed to enter the bladder if it can be possibly avoided; for after such treatment I have seen a simple gonorrhœa anterior become a gonorrhœa posterior and a cystitis colli with severe tenesmus; twice I have observed epididymitis after it, but I cannot decide whether *post hoc* or *propter hoc*.

These considerations caused me to devise a method which would have the advantages of the combined mechanical and chemical treatment, and at the same time avoid the evils I have mentioned. For this purpose I constructed nickel-plated bougies with grooves. These bougies are slightly conical and twenty-five centimetres in length. They have six grooves, which are about a millimetre and a half deep, and become shallower towards the point, stopping entirely at about five centimetres from the point, so that the front part of the bougie is entirely smooth.[1] Into the grooves of these bougies I pour a paste, which hardens at the ordinary air temperature. With respect to the composition of the paste, I recommend the following:—Cacao butter, 100 parts; nitrate of silver, 1 to 1·5 part;[2] balsam of copaiba, 2 parts. I tried, also, other preparations, such as resorcin, iodoform, zinc, and iod-natrium, but found them all inferior to the nitrate of silver. With regard to the preparation of the bougies, I must lay stress on the fact that the salve must not be heated too much, for in that case the nitrate of silver would be reduced to silver and would be inefficient. Therefore, put about two teaspoonfuls of the paste into a small vessel and heat it slowly and carefully. The vessel must not become so warm that it cannot be touched with the bare hand. Such a degree of heat is not necessary to dissolve the paste, and, as I have shown, is injurious. Neither is it necessary to wait until the entire contents of the vessel are melted, for if so the already dissolved salve becomes too hot and reduced. After dissolving, the salve is poured over the bougie, which is horizontally laid over a vessel to catch the drippings. After the salve has become hardened the bougie is smoothed with any sharp-edged tool. Care must be taken that the smooth front part of the bougie is left uncovered by the salve. Before using, draw the bougie several times through the hand, the warmth of which will cause sufficient of the salve to melt to lubricate the metallic surface of the bougie. The smooth front part of the bougie is rubbed with glycerine so that the instrument, if the size corresponds to the diameter of the urethra, will easily pass. The grooved bougie leads the salve beyond the narrowed places. At the temperature of the body the salve melts in one minute.

The greater efficiency of medicaments in this form over injections is clear, as the oily cacao butter will keep the

[1] Weiss and Son, of 287, Oxford-street, London, manufacture these bougies, for which an English patent has been applied for.

[2] Old-standing cases require more than one part of nitrate of silver, but I should not recommend more than 1·5.

Digitized by Google

ingredients in closer and longer contact than water. As to the glands and laminæ of the urethra, it is probable that the thick fluid matter enters them more easily after they have been dilated by the bougie. Of the bougies described, I use Nos. 18 to 23, French (Charrière). I never use smaller than No. 18, but prepare the urethra with soft bougies until this size will pass. As soon as this is accomplished I begin the cure with my grooved bougies, which I pass daily. If there is difficulty in passing No. 18, I employ the same sized bougie the next day, and then pass on to No. 19, &c.

After using these bougies I have never witnessed a case of chill or fever, but I will not say that this could not occur just as after passing ordinary bougies. The pain or disagreeable feeling is not greater than that caused by the introduction of any other instrument into the urethra. Nay, the well-known burning in the urethra frequently experienced by patients in passing urine after the first application of the bougie will often be entirely absent. The longer the bougie is left in, the more favourable is the effect on the infiltration. Some patients feel burning and tenesmus after a few minutes, others after half an hour, and others still later. The time during which the bougie may remain in is dependent on these circumstances. Although the salve is so prepared that it cannot injure the normal parts, I avoid introducing it unnecessarily into the posterior portion of the urethra, whence it would flow into the bladder. I effect this by passing the bougie, in a case of gonorrhœa anterior, only so far that its point just touches the musculus sphincter vesicæ internus. As the grooves with the salve begin at a distance of five centimetres from the point, none or very little of the salve will flow into the posterior urethra. In a case of gonorrhœa posterior I push the bougie further, so that its grooved part lies in the partes membranacea and prostatica. Here we cannot avoid a little of the salve flowing into the bladder. The results I have obtained with this treatment are satisfactory. On an average I succeeded by ten applications to effect a cure of cases of chronic gonorrhœa which had before proved very obstinate. In a few cases twenty and more applications were necessary. Frequently after using a very small number of bougies a striking improvement was visible.

Whether a chronic gonorrhœa which no longer shows a secretion at the meatus will improve can be decided by simply examining the urine with the naked eye. The quantity of gonorrhœal flakes, their size, and length will diminish with the gradual process of cure. The microscope teaches us that at the beginning the thick flakes are almost entirely composed of pus-corpuscles, while epithelial cells are but few. With the improvement of the chronic gonorrhœa the quantity of pus-corpuscles diminishes, and that of epithelial cells increases, till at last but few pus-corpuscles are to be found here and there embedded in the epithelial cells. Thus we are enabled exactly to observe the different stages of chronic gonorrhœa. More than once I could readily, after two applications, perceive a difference in the composition of the flakes in so far as the proportion of epithelial cells to pus-corpuscles had changed in favour of the former. Altogether by this procedure I have cured about fifty obstinate cases of chronic gonorrhœa, which had resisted all other methods: twenty-seven of these had been cases of a year and a half's standing, twelve of more than a year's standing, and others less.

Berlin.

THREE CASES OF SLOUGHING ULCER OF THE PENIS.

By FREDERICK W. LOWNDES, M.R.C.S. ENG.,
SURGEON TO THE LIVERPOOL LOCK HOSPITAL.

CASE 1.—James P——, aged twenty-three, a coach-smith, consulted me on Oct. 22nd last for phimosis and ulcers. The inguinal glands on the left side were indurated. He first noticed the fact that he was sore a week after sexual intercourse, and he had been suffering for three weeks before he came to me, having been under the care of a chemist. Hearing this, I examined him very carefully, and as the prepuce could not be retracted, I syringed it out repeatedly with warm water. There was no offensive odour nor any evidence of slough. I ordered him to inject black wash under the prepuce several times a day, and to take a pill containing two grains each of grey powder and Dover's powder night and morning. Late in the evening of the 24th I was sent for to see him at his residence in consequence of hæmorrhage. On arrival I found a most offensive discharge coming from under the prepuce mixed with blood. I at once slit the latter up, and found that a considerable portion of the glans had sloughed away. The patient stated that the discharge began to be offensive in the evening of the 22nd, and that the bleeding had been going on all the afternoon. I stopped the pills and gave him a mixture containing carbonate of ammonia and laudanum, to be taken every few hours. There was no further hæmorrhage after the glans was fully exposed, and the parts were dressed with lead and opium lotion. The next day he was much better and the slough had separated. I therefore had the parts well dusted over with iodoform powder, which was repeated at short intervals. The patient made a rapid recovery. There was no induration or any other indication of syphilis, and the parts were perfectly healed in a few weeks.

CASE 2.—John D——, aged eighteen, a tramcar guard, was admitted into the Lock Hospital on Nov. 9th with phimosis and ulcers. He stated that he began to feel sore four days after sexual intercourse, and that he had been suffering for one month previous to his admission. There had been some hæmorrhage latterly, and he had received no proper medical treatment. I saw him on his admission, and, finding a most offensive discharge, at once divided the prepuce. Part of the corona glandis had sloughed away with a portion of the furrow between it and the inner prepuce, leaving so deep a cavity that I feared lest the urethra should become involved. Iodoform, in fine powder, was applied; a mixture containing carbonate of ammonia and laudanum was given thrice daily; and the patient was ordered to keep in bed. He progressed most favourably until 3 A.M. on the morning of the 14th, when severe hæmorrhage occurred from the wound. The resident superintendent (Mr. Serjeant) was called up, and, finding him in a very weak state, sent for me. On my arrival I found that the hæmorrhage, which had been evidently venous, had ceased, but the patient was in a very exhausted state. Brandy had been administered, and I ordered this to be repeated at short intervals. I cleared away all the clots, cleansed the wound, and plugged it up with lint saturated in a strong solution of perchloride of iron. There being no further hæmorrhage, in a few days the iodoform powder was resumed, and the patient completely recovered. There were no manifestations of syphilis, and it was evidently a case of chancroids taking on sloughing action from neglect, and exposure of the patient to cold and wet in consequence of his calling.

CASE 3.—Wm. D——, aged thirty-eight, seaman, was admitted into the hospital on Dec. 7th with a sloughing ulcer of the furrow, corona glandis, and part of the glans. It was superficial, was of short duration, and separated in three days, leaving a healthy surface. The treatment was the same as in the previous cases, except that strong opium lotion was used at first, followed by iodoform ointment. There was no hæmorrhage whatever.

Cases of sloughing ulcer are much less frequent than they were twenty years ago; hence the appearance of these three cases within so short a period seems to me to deserve notice. My connexion with the hospital as surgeon extends to ten years, and the comparative rarity of this form of sore, with its much greater frequency twenty-five years ago, when I attended as a student, is very striking. During a period of eighteen months I can remember three cases where the whole of the penis was lost, in addition to many others where there was considerable mutilation. My colleague, Dr. Bernard, who saw all the above cases, informs me that during his period of office, now nearly four years, he has had about four cases, two of which were complicated with hæmorrhage. We both rely upon opium, administered internally, as a most valuable remedy; and we also employ iodoform, partly as a very useful application in promoting the healing process, partly as a most powerful deodoriser to the horrible effluvium which generally arises from sloughing ulcers of any kind, wherever situated. A very convenient mode of application is by keeping it finely powdered in a box with a lid perforated like a pepper-box (though not quite so finely), and with one or two Tonquin beans, which render it more pleasant, but no less effective.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

SEAMEN'S HOSPITAL, GREENWICH.

NECROSIS AND NON-UNION FOLLOWING COMPOUND FRACTURE OF FEMUR; AMPUTATION OF THIGH; SECONDARY HÆMORRHAGE; LIGATURE OF COMMON FEMORAL ARTERY; REMOVAL OF REMAINDER OF FEMUR; RECOVERY; REMARKS.

(Under the care of Mr. JOHNSON SMITH and Mr. TURNER.)

In this case, where an unsuccessful attempt had been made to save a compound fracture of the femur, there are several points of interest. The chief one is, as Mr. Turner remarks, the secondary hæmorrhage from the stump after amputation of the thigh, an operation which was only resorted to after the removal of much necrosed bone and the failure of attempts to cause union. The hæmorrhage was very profuse, and there was considerable difficulty in arresting it before the common femoral was ligatured. In cases of hæmorrhage from a stump such as this, the course open to the surgeon, provided the wound is too sloughy to permit the application of a ligature to the bleeding point, is to ligature either the external iliac artery or the common femoral. At one time the external iliac was ligatured by preference under such circumstances, but the greater ease with which the common femoral can be reached is an important consideration, and this case is an evidence amongst others of its efficacy. The cases of varicocele are an illustration of a method of successful operation for that disease. Although no injury to the joint followed aspiration of the knee in the case of fracture of the patella, so little good has been produced by it, in the operator's experience, that he is opposed to the practice.

William M——, aged eighteen, a sailor, was admitted on Sept. 12th, 1882, under the care of Mr. Johnson Smith. Four months before admission the patient fell down the hold of his ship and received a compound fracture in the middle of the right thigh-bone. The wound healed at sea. On admission there was about two inches shortening, and the femur was bowed outwards. There was but slight union, and the opposed ends of the upper and lower fragments of the shaft were much thickened by the deposit of new bone. Over the most prominent part of the outer surface of the thigh was a sinus leading down to the bare bone. Several sequestra were removed from this on Oct. 24th by Mr. Makins. During the winter and spring the patient suffered from renewed ostitis of ends of fragments, with much pain, and free discharge from the wound. In consequence of the necrosis, continuous pain and exhausting discharge, amputation of the thigh just above the seat of fracture was performed by Mr. Johnson Smith in June, 1883. The soft parts were sodden and inflamed. A silk ligature was used for the femoral artery. This came away on the sixteenth day. Three days afterwards—i.e., on the nineteenth—very profuse bleeding, evidently from the main vessel, came on. This was temporarily arrested with considerable difficulty by Dr. Penny, by pressure on the stump and common femoral artery, until assistance arrived. Mr. Turner, in Mr. Smith's absence, tied the common femoral artery three-quarters of an inch below Poupart's ligament. A chromicised catgut ligature was used. There was no recurrence of the hæmorrhage, and the patient, as far as ligature of the artery was concerned, did well.

In August, 1885, the man came under the care of Mr. Bates, to whom we are indebted for the further account of the case. The patient was then complaining of [illegible] in the stump. There was a good deal of purulent discharge from the end of the stump, through three sinuses situated near the line of the incision; a probe passed into these sinuses carious bone extending for some distance up the shaft of the femur, which was considerably thickened. He was sallow and losing flesh, his appetite was bad, and he suffered [illegible] loudly for morphia injections to relieve the pain at night and give him sleep. On Aug. 28th he was placed under ether and the bone examined. This was found to be in a dry carious condition for a considerable distance, and was removed at the hip-joint. An attempt was made to reflect the periosteum, but was only partially successful. The wound was dressed antiseptically. He did well afterwards, having much less pain, and was soon able to do without morphia. An abscess formed over the front of the stump, but evacuated without incision. He got up towards the end of September, and left the hospital in October. The wound has since continued closed, and the stump is firm. Now (January, 1886) he is strong and muscular, and able to get about with considerable facility, wearing a stop-action artificial leg, and walking with the aid of a stick.

Remarks by Mr. TURNER.—The interest of the above case consists chiefly in the secondary hæmorrhage following the amputation of the thigh. The bleeding was so excessive that it is probable it was caused by an extension of sloughing and ulceration to the main vessel, above the seat of ligature, and that some considerable part of the artery had given way. Pressure or ligature near the spot was obviously out of the question; the tissues, even at the time of the amputation, were sodden and inflamed, so that the arterial coats on the occurrence of the secondary hæmorrhage must have been softened and diseased for some little distance above. The parts around the common femoral artery were healthy, and the catgut ligature easily applied.

TWO CASES OF VARICOCELE IN WHICH THE VEINS WERE LIGATURED BY KANGAROO-TAIL TENDON; REMARKS.

(Under the care of Mr. TURNER.)

A. B——, aged thirty, a sailor, was admitted in June, 1884, with a considerable varicocele on the left side. He complained of much testicular pain, amounting almost to neuralgia, and had been twice operated on before at other hospitals; on one occasion the veins had been subcutaneously divided between two hare-lip pins, in the manner advocated for varix by Mr. Henry Lee, and on another, a twisted silver wire had been applied round them. He was given ether, and an incision was made over the upper part of the scrotum exposing the cord. The vas deferens having been separated from the other constituents, an aneurysm needle was passed round the dilated veins and threaded with a kangaroo-tail tendon. The latter was then tied tightly round the veins in a double knot, cut off short, and the wound united with silver sutures. He did very well, and except for a little œdema of the scrotum he made a rapid recovery. He was admitted about six months afterwards for another cause, and was then free from all testicular pain, and there was no return of the varicocele.

The second case—also a sailor—requires no lengthy description. The patient had, however, not been operated on before. The veins were tied with kangaroo-tail tendon, as in the first case, and the wound united almost by first intention. The varicocele was cured—at any rate, for the time,—but he has not reported himself since. In both cases antiseptic precautions were employed.

Remarks by Mr. TURNER.—The above method of treating varicocele I first saw practised by Mr. Holmes. It has the advantage of simplicity; the wound can be closed and may unite at once; the operator can see exactly what he is doing; the vas deferens and attendant spermatic artery run no risk; and it is easy not to include the whole mass of veins, and consequently, the testis is in no danger of sloughing.

CASE OF FRACTURED PATELLA TREATED BY ASPIRATION OF THE JOINT.

(Under the care of Mr. TURNER.)

R. S——, aged sixty-six, was admitted on Dec. 11th, 1884, with a transverse fracture of the patella. There was considerable swelling of the joint, and the fragments were separated some two inches or more. Aspiration of the joint was performed, but only about half to three-quarters of an ounce of blood could be abstracted, although the bottle was repeatedly exhausted. There was no appreciable difference in the swelling after the operation; during its performance the tube was several times obstructed by blood-clot, which required removal. Martin's elastic bandage was applied, and no bad results of any kind followed. On the subsidence of the swelling the fragments were approximated by means of Malgaigne's hooks and strapping, and the patient made

Digitized by Google

a good recovery. On his discharge on Jan. 31st there was about half an inch separation of the fragments.

Remarks by Mr. TURNER.—The practice of aspirating the joint in cases of fractured patella has been resorted to some five or six times by my colleague, Mr. Johnson Smith, at the Seamen's Hospital. One case died the next day of cardiac disease, a result quite unconnected in any way with the operation. The other cases have been followed by no bad symptoms; except in one where the blood in the joint was fluid, very little has been drawn off, and no very evident good has followed the practice. At St. George's Hospital about a dozen cases have been treated in this way; some have derived benefit from it, but in others only very little blood has been withdrawn. No harm has followed in any case.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

REMOVAL OF A PORTION OF A TRACHEOTOMY TUBE WHICH HAD BEEN LODGED IN THE RIGHT BRONCHUS FOR TWO DAYS; REMARKS.

(Under the care of Mr. RICKMAN J. GODLEE.)

WE are indebted for the following notes to Mr. C. D. Green, registrar.

A. L——, male, aged three years and a half. Tracheotomy was performed on Nov. 19th, 1884, for the relief of dyspnœa from acute catarrhal laryngitis; the child had been unable to breathe for more than a few minutes without the tracheotomy tube since the operation, but was otherwise in perfect health. On Nov. 14th, 1885, attention was drawn to the child not breathing comfortably, and on examination it was found that the shield of the tracheotomy tube it was wearing (a vulcanite one) had become displaced and the intra-tracheal portion could nowhere be found. A bent probe was introduced into the trachea, but no certain evidence of the presence of a foreign body was obtained. Another tracheotomy tube was introduced without difficulty, and the breathing was relieved. Two days later (November 16th) it was found that the breath sounds over the right lung were distinctly less than over the left, there were some general bronchitic signs, and the temperature had risen to 103° F. A careful search had been made for the missing portion of the tube, but it had not been found. It was then inferred that it must be lodged in the bronchus. Chloroform was administered through the tracheotomy tube, and the child being fully anæsthetised, the tube was removed and a pair of curved tracheal forceps (Mr. R. W. Parker's pattern) introduced through the tracheal opening, and the missing portion of tube grasped and removed, after several unsuccessful attempts both with the forceps and with a bent wire. It was believed that the bifurcation of the trachea was once grasped; there was a little bleeding, and a small piece of mucous membrane was brought away. The child had no bad symptoms, and is still under treatment for the restoration of the natural manner of breathing.

Remarks.—The fact of a second tracheotomy tube being worn during the two days preceding the removal of the foreign body, and the absence of urgent dyspnœa, leave little doubt that it must have passed beyond the trachea into the right bronchus, which it must have pretty completely filled; its smooth surface being covered with mucus, and the fact of the forceps readily entering its cavity, rendered it sufficiently difficult to grasp. It was removed without the slightest enlargement of the original tracheotomy wound, which, having been made over a year previously, was an aperture only just sufficient to admit the tube. The delay of two days was due to there being some doubt as to whether the tube had slipped down the trachea or had been otherwise lost.

ROYAL UNITED HOSPITAL, BATH.

TWO FATAL CASES OF PERFORATING ULCER OF THE DUODENUM; REMARKS.

(Under the care of Dr. Fox.)

For the following notes we are indebted to Mr. E. J. Cave.

CASE 1.—M. A——, a widow, aged fifty-six, general servant, was admitted on Jan. 10th, 1885. She states that she had an attack of "vomiting of blood" between three and four years ago, but has had no other illness, and enjoyed good health until two months ago. She then began to suffer from epigastric pain, at first only on taking food, but soon becoming constant, tormenting her night and day; it was, however, still aggravated by taking her meals. Within a week or two she began to vomit. The vomiting did not appear to be influenced by the ingestion of food, not uncommonly occurring at night, and she would vomit large quantities, almost a chamberful, two or three times a week. After an attack of vomiting the pain would cease for a few minutes. For the last month the vomiting has recurred more frequently, latterly two or three times every day, a much smaller quantity being ejected at each attack; and for the last fortnight the vomit has been dark, and, as she thinks, contained blood. From the commencement her appetite has been bad, and she has gradually lost ground, getting perceptibly thinner. Her bowels were mostly constipated until the day of admission, when they were open several times while in bed, the motions being quite loose and black. She has kept her bed for the last three days. The family history is unimportant, except that she had three miscarriages and twelve children at term, all of whom died within a year of their birth. All, she says, died of "dropsy"; none had a rash on the skin, nor did any of them "snuffle." There is no history nor sign of syphilis to be discovered in the patient herself.

On admission the temperature was 98°. She looked thin and anxious; eyes sunken; skin cold to the touch, and covered with a clammy sweat. The pulse could not be felt at either wrist. The tongue was rather dry, with a thin brownish fur. Respiration 40; rather sighing; purely thoracic. Lungs resonant in front; a little dulness at the bases posteriorly. Her collapsed condition precluded a complete examination. The heart's apex was very indistinctly felt in the fourth interspace, just inside the nipple line; sounds feeble and more clearly heard in fourth space than lower. Liver dulness began at the fourth space in the nipple line, and extended to the costal margin. Abdomen distended and tympanitic. Some little tenderness, generally diffused; no signs of fluid effusion: spleen impalpable. The urine was passed in the bed; but a little, withdrawn by the catheter, was acid in reaction and free from albumen. Opium was freely administered, but the collapse persisted, and she died in two hours.

The post-mortem examination disclosed intense peritonitis, with false membrane, puro-lymph, and chyle in the peritoneal cavity. In the first part of the duodenum, just beyond the pylorus, were two ulcers—one as big as a half-crown, with slightly thickened edges, sloping to the base; the other, in the upper wall of the bowel, was as big as a sixpence, clean, and punched out in appearance, with no thickening around. The base was perforated, permitting a free escape to the contents of the bowel. There was also a cleanly punched out ulcer in the lesser curvature of the stomach, nearer the œsophagus than the pylorus, and extending as deeply as the muscular coat. There were no other morbid appearances throughout the alimentary canal. The vessels appeared healthy to the naked eye, but the aorta was considerably atheromatous. The heart was healthy, with an adherent white patch on the pericardium. There was some collapse and œdema of the bases of the lungs. The liver, kidneys, and spleen were healthy. The contents of the intestinal canal were yellowish; there was no blood.

CASE 2.—H. H——, aged forty-five, a housemaid, single, was admitted in December, 1884. She enjoyed good health until a week before her admission, when she began to complain of pain in her abdomen and general malaise. Her bowels being constipated, she took some patent aperient pills, which procured a daily evacuation. On the evening of the second day before admission she attended a meeting of the Salvation Army, where she was taken suddenly ill and had to be carried home. The next morning she began to vomit, and for the previous twenty-four hours the vomiting is said to have been almost incessant, and she is said to have also had retention of urine.

On admission the temperature was 96°. She was in a state of extreme collapse, with rapid, feeble, almost imperceptible pulse. Lips livid; cheeks blue. Extremities very cold; skin cold and clammy. She lay on her back with her knees drawn up. Was very restless; complained of intense abdominal pain. Thoracic organs normal; respiration purely thoracic; no abdominal movement. Abdomen moderately and evenly distended, and everywhere tender, but the tenderness especially marked in the right hypochondriac region. The bladder contained about half a pint of normal urine, which was drawn off. She did not vomit after admission.

Digitized by Google

Opium was administered. She remained sensible, and died collapsed the same afternoon.

Necropsy.—General peritonitis. A good deal of thin brownish fluid in peritoneum. Some adherent lymph in the sulci between adjacent coils of intestine, here and there glueing them together. There was a round perforation in the anterior wall of the first horizontal portion of the duodenum, the perforation being the whole base of a small ulcer situated about half an inch beyond the pylorus. The edges were sharply cut and sloping, so that while the inner surface was as large as a fourpenny-piece, the perforated base was smaller, the ulcer being funnel-shaped. The rest of the alimentary canal was healthy; there were no other ulcers, and the vessels appeared quite healthy. There was slight atheromatous change in the aorta. The remaining viscera were normal in appearance. The morbid specimens in this and the preceding case were exhibited at a meeting of the Bath Pathological Society.

Remarks by Mr. CAVE.—Although these ulcers are comparatively rarely met with in the duodenum, yet clinically and pathologically they differ little from the common round ulcers of the stomach; they are only separated by the pylorus. The second case illustrates very forcibly the latent course which gastric and duodenal ulcers not very uncommonly pursue, and which is said to be even more common with duodenal than with gastric ulcers. These acute cases appear strongly to support the theory of causation by interference with the vascular supply first propounded by Virchow. Both these women were *in extremis* on admission to hospital; but keeping in view the recent advances in abdominal surgery, one would very carefully consider the advisability of opening the abdomen in similar cases seen at an earlier period and in less desperate straits. Beyond the fact of the sudden onset of peritonitis, the exact diagnosis of the primary lesion must often remain doubtful; and the question arises, Should the abdomen be explored in such cases? I think the answer must be in the affirmative.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Intra-cranial Tumours.

THE special meeting devoted to the Pathological Anatomy of Intra-cranial Tumours took place on Tuesday last before a most numerous gathering of members of this Society, the President (Dr. J. S. Bristowe, F.R.S.) being in the chair.

Dr. J. S. BRISTOWE showed a Tuberculous Tumour, the size of a marble, occupying the corpora quadrigemina and pressing on the iter a tertio ad quartum ventriculum. The boy was seven years old; had general paralysis and tremors of limbs and also of articulation, and bore clinically some resemblance to the general paralysis of the insane. Tubercular meningitis closed the scene. The case was published in full in *Brain*.

Dr. GOODHART showed a specimen of Gliomatous Enlargement of the Cerebellum, Pons Varolii, and Medulla Oblongata obtained from a boy aged nine years. The chief symptoms were staggering gait and difficulty in swallowing, inability to close the right eye, with complete right hemiplegia, occipital headache, some rigidity of left arm and leg, and a semi-comatose state. It was an illustration of a somewhat rare form of disease of which Dr. Wilks had shown a specimen to the Society in 1856, and on which Dr. Angel Money had read a paper before the Royal Medical and Chirurgical Society. The second specimen was a Psammo-sarcoma of the Brain growing from the junction of the tentorium with the falx cerebri and in the longitudinal fissure; it was of large size, but produced no tangible symptoms; the man died with malignant endocarditis and aneurysm. Two specimens of Tumours on Nerves at the Base of the Brain were shown. The first possessed one on each seventh nerve; it was removed at a post-mortem examination in 1873 by Dr. Goodhart. The case had been under the care of Dr. Wilks, and was that of a woman aged twenty-six. Deafness, with very severe pain in the eyebrow and forehead on the right side, with paralysis of the right eyeball, and the face drawn to the left side, were the chief symptoms. She was hardly able to walk, but there was no actual paralysis and no anæsthesia. The tumours were of a fibro-sarcomatous nature. The second specimen occupied the seventh nerve on one side. The patient had been five years deaf on the right side, and ultimately completely deaf. The voice was lost, and paralysis of the face had been present for three or four years. Some trouble in swallowing, so that the patient had to be fed with a tube, atrophy of the right sterno-mastoid, and aphonia, were the other chief symptoms. During life it was thought not to be a tumour, but a gummatous infiltration of membranes at the base of the brain. The next specimen was a more fibrous tumour, situate at the left Gasserian ganglion. There were anæsthesia of the face and severe pain, with ophthalmoplegia externa and interna. The optic disc was healthy. Large glands in the neck and cardiac murmurs were also noted. The patient died of cellulitis of the neck and arm, to which disease a tendency existed in her, for she had suffered from it two or three times previously. The tumour was found to press on the nerves in the wall of the cavernous sinus. A tumour of the temporo-sphenoidal lobe, taken from a lady aged sixty-six, was also shown. She had been epileptic throughout life, and imbecile for years. There was much pain and tenderness in the right temporal region, and the left side had been losing power one week. The left side of the face was paralysed, and the left arm powerless and rigid, but not the leg. The patient was not deaf. The diagnosis lay between tumour and apoplexy or softening. At the necropsy a tumour was found occupying the middle of the first temporo-sphenoidal convolution, and extending inwards beneath the lower part of the two central convolutions. This case was interesting from a point of view of localisation. The patient was not deaf, although the "auditory" centre was involved. In Dr. Goodhart's experience our knowledge of cerebral tumours was against the idea that many tumours could be submitted to surgical interference. Tumours tend to occupy the cortex, but did not flourish therein; they luxuriate in the white matter. They cause symptoms in proportion to the amount of cortex involved. Three conditions—(1) accessibility, (2) want of infiltration, and (3) reasonable size of tumours—were the requisites for surgical interference, and these conditions were, he submitted, but seldom met with together.—Dr. MONRY said that one of the objects of his paper was to show that "gelatiniform enlargement of the pons" was of a gliomatous nature.

Dr. FREDERICK TAYLOR showed, first, a Tumour of the Cerebellum from a boy aged nine. The chief symptoms were: pain, frontal and vertical; the right eye squinted outwards; inclination to the right in walking and falling to the right; he also walked unsteadily. On admission, there was paralysis of both external recti with other symptoms of intra-cranial tumour; increasing blindness and emaciation were followed by death. The glioma had a pinkish-violet appearance, and involved the floor of the fourth and the left half of the posterior part of the pons Varolii; it grew chiefly from the left side of the cerebellum; there was some internal hydrocephalus. The tumour was not distinctly encapsuled, and was of a gliomatous or a sarcomatous nature. The second specimen had been described in the Guy's Hospital Reports for 1879; it was a Glioma of the pons Varolii obtained from a man, aged forty years, in whom there was partial right hemiplegia. The third specimen was also a Glioma, occupying the frontal region and involving the right corpus striatum and adjacent parts, chiefly the right lenticular nucleus of the corpus, and not the caudate. The man suffered from rigidity of the left arm, left leg, and right arm, and lay in a semi-unconscious state, with double optic neuritis, but chiefly of the right side; the olfactory lobes were in a state of grey softening. The fourth specimen was a Fibro-sarcomatous Tumour growing out of one side of the flocculus of the cerebellum; it measured half an inch by one-third of an inch broad and a quarter of an inch thick, and gave rise to no demonstrable symptoms.

Mr. PEEKE RICHARDS showed a Tumour of Translucent Cystic Aspect, occupying the third ventricle, the size of a Tangerine orange. The specimen was referred to the Committee for Morbid Growths. The woman had been in Hanwell Asylum for six weeks, and was somewhat demented, but a state of extreme drowsiness, lasting twenty-three out of twenty-four hours, was the chief symptom; there was also left hemiplegia.

Mr. H. T. BUTLIN showed a Cerebellar Glioma of fourteen years' preservation. It was situate rather to the right of the middle line of the cerebellum, and had a spherical shape

Digitized by Google

with soft consistence and semi-translucent aspect. The tumour was single, and therefore primary. There was a history of a severe fall two months before admission into the Hospital for Sick Children; the blow struck the right side of the forehead. The corporeal movements were awkwardly performed, especially those of the left side, and there was continual shaking.—Dr. HALE WHITE, speaking of the influence of traumatism in the production of cerebral tumours, said he had examined 100 cases of tumours in adults, and found the proportion of ten males to six females to hold good in them as in children; he concluded that injury played but little part in the production of tumours.

Dr. ORD exhibited specimens and drawings of Tumours of the Cerebral Cortex, with a view of showing the possibility of localising lesions on the cortex. The first tumour occupied the left hemisphere at the upper part of the fissure of Rolando, involving the ascending frontal and the posterior parts of the two superior frontal gyri. The dura mater was thickened over the spherical gumma. The second specimen was from a case of tuberculosis, and occupied much the same cerebral area, but more of the posterior parts of the two superior frontal gyri, and it also extended deeply into the white substance. The symptoms were convulsions on one side, but no loss of consciousness in the first case, though unconsciousness was present in the second. The convulsions were followed by hemiplegia, at first partial, ultimately complete.

Dr. SAUNDBY exhibited a microscopic section and diagram of a case of Glioma of the Brain. Ataxic gait, with mental disturbance, but no distinct paralysis, were the chief symptoms, and death took place while in a comatose state. The growth involved the left second and third frontal convolutions, also the ascending frontal and the island of Reil, pressing on the corpus striatum of the left side. The second specimen was one of Multiple Tubercular Tumours, taken from a boy aged eleven, who had twitching of the left side of the face, with spasm of the left arm, and deviation of the eyes to the left. The lower half of the left ascending frontal convolution was the only lesion in the motor region, which was therefore on the same side as the motor symptoms. Other tumours existed in the occipital, temporo-sphenoidal, and hippocampal convolutions. These cases supported what Dr. Goodhart said in regard to the difficulty of localising tumours with a view to surgical interference.

Dr. COUPLAND showed (for Dr. MacDonald) a Cystic Tumour from the brain of a man aged fifty-two, who was admitted into an asylum for acute mania, on which dementia ensued six months before death. Right hemiplegia of slow onset and marked imbecility were the chief symptoms. The cyst covered the entire left hemisphere and caused considerable atrophy; there was no adhesion to the dura or pia mater, but a small vessel entered it from the pia mater. Dr. Macdonald regarded it as a congenital cyst. Dr. Coupland believed that it was a hæmorrhagic cyst, although bounded by firm investing membrane; microscopically, crystals and granules of hæmatoidin were discovered; the cyst was possibly of intra-uterine origin.—Dr. BRISTOWE said that in an early volume of the Transactions a large cyst of this kind was placed on record; there was no affection of the dura mater.

Dr. CHARLEWOOD TURNER brought forward a specimen of Tumour in the Left Hemisphere, taken from a man aged thirty-one, whose symptoms lasted three months, and began with a spasmodic seizure in the right arm and leg, and morbid creeping sensations down the same limbs, lasting five minutes. When first seen there was paresis of the right leg, but no anæsthesia. The tumour involved the centre of the white substance and those fibres which went to the anterior part of the corpus callosum, beneath the ascending frontal and parietal convolutions; it had a rounded triangular shape, and did not actually involve the grey matter. The growth was a soft glioma. The second specimen was a hard glioma, which began in the cortex and extended into the white matter; it came from a man aged fifty-five, whose symptoms lasted six months, and began with headache. He became unconscious at times, and left hemiplegia followed; also some hemianæsthesia. The posterior part of the parietal lobule, where it joins the temporo-sphenoidal lobe, was diseased in a line with the Sylvian fissure, and the growth extended into the posterior part of the corpus striatum and optic thalamus. In reply to Dr. Bristowe, he said he considered that a tumour in the lung of the first case was independent of that in the brain.

Dr. SAMUEL WEST showed a specimen of Tumour in the Temporo-sphenoidal Lobe taken from a man aged sixty-two, whose illness lasted six months and began with an accident, soon after which it was noticed that his speech was peculiar. He had also aphasia of the amnesic kind—i.e., loss of memory of nouns. He dragged the right leg, and later the right arm became weak, and other symptoms of coarse brain disease finally appeared. The tumour was situate in the left temporo-sphenoidal lobe, and did not reach the cortex, but displaced the basal ganglia and internal capsule towards the right. The presence of cavities in this soft glioma, which was primary and interesting from its size, extent, and position, was remarked upon. The absence of characteristic symptoms of tumour till three weeks before death was noteworthy, as was also the fact that he had occasional tremors, most marked on the left side. Dr. West considered that there might be some influence in the rate of growth in the production of symptoms.

Dr. HADDEN exhibited: (1) Drawings of the naked-eye and microscopical appearances of psammomata of the choroid plexus. (2) Specimens (with drawing) of a myxo-chondroma of the falx cerebri pressing on and embedded in the right paracentral lobule; there were no symptoms during life. (3) Round-celled sarcoma involving the white matter and deeper layers of the cortex of the left ascending frontal and adjacent parts of the second and third transverse frontal convolutions; the patient died soon after admission, but there was a history of numerous epileptic attacks. (4) Glioma involving the right caudate nucleus, the posterior two-thirds of the lenticular nucleus, the claustrum, external capsule, the posterior half of the motor part of the internal capsule, and all the sensory portion, as well as the upper two-thirds of the optic thalamus; the only localising symptom was slight anæsthesia of the left leg. (5) Simple cyst in the left lobe of the cerebellum, one inch in diameter, containing clear limpid fluid. There were no traces of old hæmorrhage or of hydatid membrane. The chief symptoms were paroxysmal occipital headache, vomiting, optic neuritis, and staggering gait.

The following gentlemen showed card specimens of tumours of the brain:—Dr. Ladiard, Dr. Savage, Dr. Beevor, Dr. Ogilvie, Dr. Hebb, Dr. Ashby, Dr. Chaffey, Mr. D'Arcy Power, and Mr. Ernest Clarke (living specimen).

MEDICAL SOCIETY OF LONDON.

Moot Points in Syphilis.

LAST Monday, at this Society, Mr. JONATHAN HUTCHINSON, F.R.S., delivered his third Lettsomian Lecture; Dr. W. M. Ord, President, being in the chair.

The lecturer said that the number of important questions still undetermined in respect to the transmission of syphilis from parent to child is very great. Indeed, it is remarkable how comparatively young almost all our knowledge is on this subject. It is not long since contagion during parturition was held to be the only method by which the mother could convey syphilis to her child. Whether the father could transmit it was a vexed question, and this idea was ridiculed by a leading physiologist not many years ago. Almost everyone now accepts the doctrine that a tainted father may beget tainted offspring; but some of our best authorities hold that if a pregnant woman contracts syphilis it is quite impossible that her disease can hurt the child in her womb. Great and peculiar difficulties beset the investigation of the transmissibility of inherited syphilis. The evidence on questions relating to the inheritance of syphilis is but seldom absolutely conclusive; it yields at best only a strong probability. Mr. Hutchinson said that the general tenour of facts conveyed much more of conviction to his mind than did the seeming lesson of an isolated case, however clearly stated. The evidence which leads to the belief that the father can transmit syphilis independently of the mother is peculiarly of the kind referred to. It was next to impossible to prove that the mother has never suffered. Inheritance from the father is not only possible but common. It is possible that the mother may show but few symptoms of the disease, but that she always first receives the disease without the occurrence of primary and secondary symptoms is possible now and then, but it cannot happen often. It is common, however, for the mother to show no symptoms. Many years ago Mr. Hutchinson published a series of cases apparently confirming the observations of Ramsbotham, Harvey,

Digitized by Google

and others, that the fœtus might infect the mother, but there is the objection that the mother might possibly have had syphilis herself. We want proof of two things: (1) that a woman may carry a syphilitic child without herself suffering in any obvious manner, and (2) that although she shows no symptoms, yet she does in reality receive a taint. Of the first there was abundant proof; of the second the evidence was less convincing. Does Colles' law (that a sucking infant cannot infect the nipple of its own mother) stand the test of time? Mr. Hutchinson considered that it did. In not one case of chancre of the nipple in Mr. Hutchinson's experience was the infant which conveyed infection the offspring of the woman who acquired the chancre. To those who, with Kassowitz and others, doubt that the fœtus infects the mother, Mr. Hutchinson would suggest that there is nothing improbable in such an occurrence. The next question touched upon was the possibility of a mother who contracts syphilis during her pregnancy infecting the fœtus. Mr. Hutchinson has met with cases which appeared to prove the affirmative. He considers that it matters not whether the father or the mother be the cause of the inherited syphilis; its transmission is just as certain or uncertain, and the resulting disease does not differ in severity. Inheritance from both parents instead of one probably makes no greater difference to the child than does vaccination on both arms instead of one. Mr. Hutchinson was not forgetful that multiplicity on the part of the primary lesion does to some slight extent heighten the disease, but still contagion acquired or inherited from one source is sufficient for the full result. With regard to transmission to many children in succession, he remarked it was but seldom that proof could be obtained of a tendency to transmit syphilis extending over many years. But the lecturer narrated exceptional cases in which children of the same parents, though born at long intervals, yet suffered definitely from the taint, and in doing so he directed attention to some questions which are still matters of debate. (1) Is there any reason to believe that when syphilis shows itself in several children of the same family its degree of severity is less in the younger than the elder ones? (2) Is it usual for some children to escape entirely when elder and younger ones suffer severely? (3) When children in the same family show very widely different degrees of severity in symptoms during infancy, can anything be predicated from that fact as to their proneness to suffer later on in life? Mr. Hutchinson believes that there is no reason to think that the transmission of syphilis is ever a thing of less or more, but rather that if a child inherits any taint it inherits the whole malady; the varying degrees of severity are to be explained in the same way as we explain the differences observed when scarlet fever is passing through a community. Many cases were narrated in support of his views, and some remarkable ones, showing that a younger child may suffer most. The lecturer next passed on to the consideration of bone affections in relation to syphilis, adducing the hypothesis of M. Parrot that rickets was due to syphilis, and quoting the investigations of Dr. Barlow and Dr. Lees on syphilitic osteal affections during the early months of life. He saw no reason why syphilis and rickets should not mix. The question as to whether deep ulcerations of the palate and pharynx, when met with in young persons, are usually due to syphilis or to scrofula, was next discussed, and evidence was brought forward pointing strongly to the conclusion, in Mr. Hutchinson's opinion, that syphilis was chiefly responsible for such ulcerations. A few words were said as to the possible dependence of what has been called ringworm of the tongue upon inherited taint. Whilst admitting that some cases were due to congenital syphilis, he could not allow that all owned this etiology. The next subject entered upon is comprised in the question, "Are there any chronic skin diseases which are due to inheritance of syphilis?" The chief feature of this subject was Mr. Hutchinson's declaration that such diseases as psoriasis and lichen occurring after the infantile period of life had passed away were not syphilitic; inherited syphilis may cause such cutaneous lesions during the early years of life, but not later on. Coming next to diseases of the nervous system, Mr. Hutchinson still maintained that they were rare from congenital syphilis. Dr. Barlow had published cases showing that meningitis, neuritis, gummata, and vascular disease did occur in congenital syphilis, and might be responsible for impairment of mental powers and coarse brain disease, but still he (Mr. Hutchinson) considered that such cases were not frequent. Epilepsy and chorea might be due to syphilis, but they differed, on Dr. Hughlings Jackson's authority, in no respect from the same affections differently acquired. No case of locomotor ataxy had been ascribed to congenital syphilis; paralysis of single ocular muscles was practically unknown. Mr. Hutchinson had seen one case of ophthalmoplegia externa from inherited syphilis. True tertiaries are rare in congenital syphilis. A case of defective brain development, with atrophy of optic discs in association with inherited syphilis, was narrated. It was not unfrequent for congenital syphilis to damage in some slight degree the whole bodily development. Sometimes there appeared to be a special defect in the sexual development. Idiocy and juvenile dementia are occasionally due to congenital syphilis; but the lecturer did not concur in Dr. Judson Bury's belief that atrophic and sclerotic conditions of the brain, due to inherited syphilis, were of rather frequent occurrence; the experience of Dr. Langdon Down also supported him. As to the nature of pemphigus in infants, Mr. Hutchinson asked, Why should the inherited taint so deviate from the rule as to appear during the first week and end fatally before the second week, as happened in pemphigus? Why should it show its effects so soon after birth? and why should a local and not very severe disease be so prone to end in death? Another interesting question was why syphilis so often caused abortion, seeing that syphilitic infants are generally healthy at birth, and remain so for three or four weeks. Why, if it can kill the fœtus so commonly, does it at the same time leave so many in perfect health until the influence of open-air life has been brought to bear through a definite period? Nor is it easier to explain why one sex should suffer more frequently from the results of inherited taint than the other. Mr. Hutchinson suggested that cases in which twins, one or other, or both, suffer from inherited syphilis should be followed up through as long a period as possible; that cases in which women acquire syphilis during pregnancy, with especial attention to the question of the freedom of both parents from any former taint, also required investigation. In these cases it is desired to ascertain the effect upon the previously healthy fœtus of syphilis acquired of the mother at different periods of pregnancy. All instances of exception or apparent exception to Colles' law, all instances of children born alive with indications of syphilis upon them, all cases of pemphigus infantum or of other syphilitic eruptions making their appearance during the first week of life, ought to be diligently recorded, and here there was a wide field for investigation by "family doctors."

At the close of the lecture a vote of thanks to Mr. Jonathan Hutchinson was proposed by Mr. WILLIAM ADAMS, seconded by Dr. STEPHEN MACKENZIE, and carried with acclamation.

OPHTHALMOLOGICAL SOCIETY.

Shrinking of Conjunctiva.—(? Pemphigus) Spectroscopes.—Amblyopia from Bisulphide of Carbon.—Synchysis Scintillans.—Atrophy of Iris.—Meningitis after Excision of Eyeball.—New Instrument for Refraction Tests.

AN ordinary meeting of this Society was held on the 28th ult., Mr. Henry Power, Vice-President, in the chair.

Dr. W. A. BRAILEY showed a case of Shrinking of the Conjunctiva, with a view to obtaining the opinion of members as to the nature of the disease. Already Mr. Lang thought it was a case of pemphigus; but Dr. Brailey said it was sufficiently reconcilable with the previous existence of granular lids. The right eye showed a pannus of the cornea above and opacity of the cornea below; the conjunctiva was much contracted. The left eye was cicatricial on the surface of the upper eyelid, and there was also opacity of the cornea.—Mr. LANG said there was no evidence of pemphigus on the mucous membranes or skin in the case he now showed, and no evidence of granular lids; still he regarded the cases as pemphigus of the conjunctiva. In reply to Dr. C. E. Fitzgerald, Mr. Lang said that there was little that could be done for his patient in the way of treatment.—Mr. B. CARTER considered that there was no appearance of pemphigus; the case was one of chronic conjunctivitis. The patient had been under his care a few years ago, at which time he had operated, having dissected off the conjunctiva from the lower half of the cornea and transplanted a piece of healthy conjunctiva from a rabbit; th

Digitized by Google

new conjunctiva, however, underwent gradual degeneration and shrinkage. He had never been able to see any likeness of the disease to pemphigus.

Dr. REID (Glasgow) exhibited a Polarisation Spectroscope, designed to detect colour defects in the spectrum and their exact position; a similar instrument could be arranged to determine the position of the neutral point or points in dichroic vision. He also showed a perimeter for use in achromatopsia; and an ophthalmoscope adapted for use with the electric light; and provided with a grating by which the condition of the superficial layers of the retina as to transparency could be ascertained.

Mr. JULER exhibited his Ophthalmoscope for Electric Light; it had a concave mirror of short focal length and a small Swan light.—Mr. B. CARTER said that his own ocular fundus had been examined by Mr. Juler, and the light was more pleasant than that from the gas or ordinary lamp.

Mr. MARCUS GUNN brought forward a man suffering from Toxic Amblyopia due to the action of Bisulphide of Carbon, which he used in preparing oil from cocoa-nut fibre. He had worked at the same occupation for fourteen years, but about sixteen months ago he changed his situation, and four months later the symptoms of illness began; the ventilation of the workshop was defective, and no doubt was a cause of the development of symptoms. There was complete red-green blindness, which might have been congenital, but probably was not. Jaeger 19 was the smallest he could read. There had been no improvement even in four months. He also showed the result of an operation on an eye damaged by severe Sympathetic Disease.

Mr. RICHARDSON CROSS showed a case of Synchysis Scintillans, in which the vitreous humour was not fluid. The pathology of these cases was, he believed, widely different. In this case neither the ciliary body nor the choroid was affected. The process was closely allied to atheroma of vessels.

Mr. G. L. JOHNSON showed drawings of a case of almost complete Atrophy of the Iris. The patient was a man aged forty-nine, who had perfect vision till eighteen years ago, when he met with an accident in which the right eye was struck by a wheel, and had to be excised. Nothing fresh was observed till three years ago, when it was noticed that the left eye was becoming impaired, and its pupil getting slowly larger and larger. After correcting errors of refraction the patient could read Jaeger 4. There was a very general atrophy of the choroid, and the iris had participated, so that a mere band remained above and below; the optic disc and macula were unaffected, and also the fundus in their immediate neighbourhood.

Mr. E. NETTLESHIP read a paper on Meningitis after Excision of the Eyeball. The case on which the paper was based occurred at the Moorfields Hospital in July, 1885, the patient being a young man who was operated upon unsuccessfully for dislocation of the lens into the anterior chamber. The eye was excised, in a state of early, but violent, suppurative inflammation, seventy-two hours after the attempted removal of the lens. The man became restless and excitable, with high temperature within forty-eight hours, and died seventy-five hours after the excision. He was attended by Dr. Stephen Mackenzie. Purulent meningitis was found at the base and between the cerebrum and cerebellum; there were no tubercles. It was remarkable that well-marked tough thickening of the pia mater and firm adhesion of the opposite edges of the longitudinal and Sylvian fissures were found, undoubtedly indicating a previous attack of general meningitis, but the early history of the patient was almost negative. All the other cases of meningitis after excision of the eye known to the writer, twenty-nine in number, were arranged in a tabular form at the end of the paper, making, with the author's own case, thirty. No cases were included in which it was known that the operation was complicated by injury or disease of the walls of the orbit. Of the thirty cases, twenty-six were fatal, and eighteen of these were examined after death and meningitis found in all; the remaining four cases recovered, usually after a long and severe illness. In a considerable majority the meningitic symptoms set in within forty-eight hours of the enucleation; but the duration of the illness, when fatal, varied more than the period of onset. Except that the meningitis usually affected the base, and was sometimes more marked towards the front and on the side of the excised eye, and that twice there was thrombosis of the cavernous sinus, there was very little macroscopical evidence of transmission from the orbit; but microscopical examination in four cases showed inflammation in or around the optic nerve, and in one inflammation and micro-organisms in the sixth nerve. It was suggested that, in spite of the rarity of visible thrombosis, the veins may in some cases be the carriers, and that (owing to the numerous anastomoses) the blood-current in the cerebral veins may sometimes be reversed, allowing septic material to pass from the orbit upwards to the brain, instead of into the jugular vein. In some cases only the convexity was affected, and in others the disease was more marked on the side opposite to the excision. In a considerable majority the excised eye had been wounded; but the author dissents from von Graefe's statement (1863) that the risk of meningitis is much greater if the eye were suppurating when excised, since it appears that in exactly half of the cases no visible suppuration was going on, or had occurred, in the lost eye. The disease is probably due to infection of the orbital wound, either by the decomposition of discharge pent up by tight bandaging, or (as was probable in two cases) by erysipelas. Complications were present in a few cases (menstruation twice, old cerebral disease twice). It is believed that, with care, the cases may be rendered much more rare than they had even hitherto been, especially by providing free drainage from the orbit when there is much inflammatory swelling. The author at present prefers excision, with suitable precautions, in all cases to evisceration, which has not yet proved its inability to cause sympathetic disease. Particulars were then given of cases of meningitis following other operations upon the eyeball; only four such were known to the writer, and in only one was a post-mortem examination made. In certain cases of meningitis after excision sympathetic inflammation had set in some time before the meningitis, a fact which seems to militate against the theory that sympathetic disease passes from the exciting to the sympathising eye by the meningeal coverings of the optic nerve.—Mr. HENRY POWER referred to a case in which he had excised the eye and some of the tissue of the orbit; chloride of zinc was used as an antiseptic to syringe out the orbit; meningitis developed, and ended fatally. This was the only case in his own experience.—Mr. BRUDENELL CARTER had never met with this accident in his practice. He always remembered the dictum of von Graefe not to remove an eye that was in a state of suppuration. Referring to the recommendation of M. Panas to employ a solution of biniodide of mercury as an antiseptic solution, he recounted how such a dilute solution could not be obtained. In one case of cancer of the eyeball, in a child, he had excised the diseased parts, and used the actual cautery to stop the bleeding; it was curious to observe how the thin roof of the orbit had offered a perfect barrier to the passage of inflammation.—Mr. CHARLES HIGGENS criticised Mr. Nettleship's paper, and said his belief was in favour of the suppuration having something to do with the meningitis, for it occurred in half the collected cases. He had never employed tight dressings for more than four hours, considering that they might do harm by favouring the absorption of septic material.—Mr. MARCUS GUNN believed that it was good practice to remove suppurating globes in a large number of cases. In his practice no pressure bandage was kept on for more than four hours.—Mr. MCHARDY referred to two other cases of fatal meningitis. One occurred in a man aged forty-six, with commencing sympathetic ophthalmitis; the offending eye was removed and was followed by suppurative meningitis, with rapid death. The other case was that of a young man aged twenty-four, who was insane, and had enucleated his own globe by means of his finger; the optic nerve was torn off close to the commissure. Death ensued in four days from acute suppurative meningitis. In some cases of extraction of cataract he operated with the patient in the prone position, which aided the lens in falling forward into the anterior chamber.—Mr. W. H. JESSOP asked whether Mr. Mules had met with any cases of sloughing of the sclerotic in his cases of evisceration.—Mr. MULES replied that since using bichloride of mercury he had not encountered any evil consequences. — Mr. J. TWEEDY had never seen any mishap after excision. In one case of an old man nearly eighty years of age, who had received a blow on the orbit, the globe was excised, and the man died the next day either from senile failure or from some accident to the brain at the same time as the injury to the eye. The man before operation was observed to be in a dazed mental condition.—Mr. PRIESTLEY SMITH had had two cases of the kind. The second case taught him a lesson as to the danger of

Digitized by Google

tightly bandaging the orbit. He could not agree that it was not well to excise a suppurating eye. The use of powdered iodoform to the orbit after operation was exceedingly valuable, and at all events harmless. If any fever arose, removal of the dressing and syringing the orbit with frequent injections of Condy's fluid should be practised, and he believed that by this timely intervention he had saved the patient's life in the second case alluded to above.

Mr. J. B. LAWFORD read for Mr. Waren Tay an account of the case of a boy aged nine who was struck on the right eye, producing a Wound of the Sclerotic on the inner side below the horizotal line. Nothing happened for ten days; then the iris became "muddy-looking," and there was complaint of pain in the eye, restlessness, and vomiting. The day after changes were noted in the vitreous humour; a day later still the eyeball was removed; in it there was evidence of incipient suppuration and commencing shrinking and puckering of the sclerotic wound. The temperature was 102° at the end of twenty-four hours. Delirium and unconsciousness set in with further fever, the temperature rising to 103·8°. He died seventeen days after the injury, and four days after excision of the eyeball. At the necropsy there were signs of extensive meningitis both at the base and over the vertex of the brain, but no evidence of tubercle or old mischief, or of the right side being more affected than the left, or of the inflammation having spread from the orbit, the tissues in which showed no special changes. The cavernous sinuses were healthy, and also the joints of the body and the other organs, with the exception of hæmorrhage into the upper lobe of the right lung and hypostatic congestion. There was a little blood in the sheath of the right optic nerve, but no microscopical evidence of optic neuritis.

Mr. P. H. MULES said that he had not seen a single case of evisceration of the globe which had not progressed satisfactorily. Far from leaving suppurating globes alone, he had always regarded suppuration as an indication for excision, and had never seen any ill symptom result. It was his practice to wash the surface of the eye with a solution of chloride of zinc, ten grains to an ounce, and also to inject the wound after the operation with the same solution, and this was daily continued. Excision of a suppurating globe always led to immediate relief of pain.—Mr. G. L. JOHNSON asked Mr. Tweedy whether a suppurating globe ever gave rise to sympathetic ophthalmia.—Mr. TWEEDY said he could not answer definitely the question.—Mr. HENRY POWER said that years ago a free excision of the globe was held to be the correct treatment of suppurating panophthalmitis.—Mr. NETTLESHIP briefly replied, and said that, as rabbits with suppurating orbits *frequently* died with suppurative meningitis, they could not be said to be in the same case as human beings. He now never put any dressing between the eyelids, though this used to be the practice of at least one ophthalmic hospital.

[Mr. Nettleship writes to us that he has ascertained since the meeting that the solution of biniodide of mercury with which he syringed out the orbit was made with iodide of potassium, in which the biniodide is freely soluble.]

Dr. C. E. FITZGERALD showed a new instrument for facilitating Refraction Tests.

Mr. LANG showed, for Dr. J. W. Barrett, a new and large-sized Microtome.

Mr. JESSOP showed a new Pupillometer.

OBSTETRICAL SOCIETY OF LONDON.

Dr. Heywood Smith. — The Oblique Pelvis of Naegele. — Gastrotomy for Extra-uterine Gestation.

A meeting of this Society was held on Jan. 13th, Dr. J. E. Potter, F.R.C.P., President, in the chair.

The PRESIDENT stated, with regard to Dr. Heywood Smith's conduct in the Armstrong case, that the Council, after careful and anxious consideration, had come to the conclusion that they were not justified in recommending the Fellows to put in force the law which provides for the removal of a Fellow. He then read the following resolution of Council:—"Having heard Dr. Heywood Smith's explanation of his conduct in the Armstrong case, it is resolved that the Council emphatically disapproves of his action in this case. That this resolution be read from the chair at the next meeting of the Society."

The following specimens were shown:—Ruptured Uterus: Mr. Drage. Section of Cancer of the Body of the Uterus, removed by enucleation: Dr. Galabin.

Dr. HERMAN read a paper on the Production of the Shape of the Oblique Pelvis of Naegele. The author said he did not propose to discuss the nature of the disease resulting in the pelvis, but only the reason of the change of shape. He showed by measurements that the disease (whatever its nature) produced dwarfing of the sacrum and destruction of part of the ilium on the affected side. He did not think that the explanation of the pelvis put forward by Dr. Matthews Duncan—viz., that it was the result of ankylosis of the sacro-iliac joint—was an adequate one. There were three main forces which produced the shape of the pelvis: (1) The body weight; (2) the action of muscles and ligaments; and (3) the innate tendency of the bones in their growth to assume a particular shape. The action of muscles and ligaments he believed to be far less effective in modifying the shape of the pelvis than the body weight, and, in the case of the Naegele pelvis, did not materially differ on the two sides. The most powerful force he considered to be the tendency of the bones to grow into their proper shape in spite of mechanical influences. In the Naegele pelvis the bones retained this power; and that was an essential difference between the Naegele pelvis and pelves, such as the rickety and osteomalacic, in which the bones were rendered by disease abnormally flexible. The Naegele pelvis was one of the simplest of all pelvic deformities, because in it we had little to deal with except altered distribution of the body weight. This was carried by the iliac beams on to the femora at angles differing on the two sides. The author believed that, as had been shown by Dr. Champneys (in opposition to what was generally taught), the effect of the pressure of the femora was to carry the acetabula upwards and outwards. He adduced in support of this view the evidence of experiments, which showed that when the femora were pushed upwards in a parallel direction the pubic bones were divaricated; and that of the pelves wasted from disuse of one side, in which the acetabulum on the side on which the unopposed pressure of one femur was exerted was carried upwards and outwards. The shape of the Naegele pelvis he believed due to the differences in the effect of this pressure on the two sides. The outward pressure was exerted to greater advantage on the sound side; therefore the acetabulum was on this side carried outward, and the symphysis pubis dragged over to that side. The iliac portion of the pelvic brim was less compressed on the sound side of the Naegele pelvis than in the healthy pelvis, owing to the pressure of the femora being less directly upwards. The author adduced measurements in support of these assertions. According to his view, the lessened breadth of the sacrum and the iliac bone on the ankylosed side was the essential change, not the ankylosis. In support of this view he cited cases in which oblique deformity resulted from atrophy of the sacrum without ankylosis, and also cases in which with ankylosis and oblique deformity the degree of obliquity was proportionate to the breadth of the sacrum. Lastly, he showed that the shape of the transversely contracted pelvis of Robert was explicable on his view.—Dr. GALABIN said that the action of the body weight on the posterior sacro-iliac ligaments, exercising force on the iliac beam and tending to evert its lower extremity, would be abolished if the joint were ankylosed. The body weight and the pressure of the femora must act vertically, but besides this there was an inward pressure of the femora, and a corresponding outward pressure of the pelvis upon the femora, due to muscles. He agreed with the paper of Dr. Champneys on this subject quoted by the author, and had taught the same views himself. The outward thrust of the lower end of the iliac beam could not be subjected to the parallelogram of forces, as the author had done; the important point was the relative length of the arms into which the sacral beam was divided by the incidence of the body weight. He thought that the study of certain pelves showed that on the whole inward pressure at the acetabula predominated. He agreed, however, with the author in one thing—viz., that the obliquity of the Naegele pelvis could be accounted for by other causes than the ankylosis, and that the deficiency of the sacral wing was more important. If for any reason the acetabulum and tuber ischii were displaced towards the middle line, the forces causing obliquity acted with constantly increasing force. There was one peculiarity of the shape of the Naegele pelvis, which supported strongly Dr. Duncan's

Digitized by Google

theory of the leverage exercised through the posterior sacro-iliac ligaments: this was the absence of curvature at the posterior end of the innominate line on the affected side. In the scoliotic pelvis and in the oblique pelvis from disease of one leg the posterior part of this line is more curved than usual, in the Naegele pelvis less curved, and this can only be accounted for by the ankylosis preventing the action of the iliac beam on the affected side.—Dr. MATTHEWS DUNCAN alluded to the increasing difficulty of making progress as the subject advanced. He was himself indebted to the work of Dr. Champneys, particularly as correcting his former view of the direction of the upward push of the head of the femur in standing. Dr. Champneys showed that the pressure, as unaffected by the action of the adductors, was not upward and inward. The ultimate result, as Dr. Galabin pointed out, of the pressure as modified by the adductors, was upward and inward. He regarded the Naegele pelvis rather as a malformation than as the result of disease; it was congenital, and might be due to the deficiency of the ossific centres. The discussion at present should be confined to the normal pelvis and its modifications in the pelves of Naegele and Robert. The introduction of others plunged one into an insoluble mass of complexities, while these pelves were well marked and uniform, and as to their shape, congenital character, and absence of bone disease, there was unanimity. He was still inclined to believe that the absence of one or both sacro-iliac joints was the great factor in these pelves. In the other morbid pelves there were several factors of cardinal importance whose influence it was difficult to ascertain and weigh.—Dr. CHAMPNEYS said that Dr. Herman's interesting paper had not succeeded to his mind in finally settling the question as to the essential cause of deformity in the Naegele pelvis. The whole subject of pelvic deformities was most difficult, and the great facts finally settled were few. As regarded the assertion that ankylosis of the sacro-iliac joint could not prevent bending of the iliac beam, he could conceive that, besides the objection brought forward by Dr. Galabin, another might be urged—namely, that a wooden beam laid across a wooden block might not be so easily bent if glued to the block as if not glued. Again, with regard to the statement that in the Naegele pelvis the bones retain their power of growing into their proper shape, we must remember the abolition of action caused by ankylosis and its effect on the nutrition of the component bones. In the pelvis of a child in which disease of one sacro-iliac joint had produced oblique deformity, which he had brought before the Society in a paper, the whole side of the sacrum as far as the coccyx was dwarfed on the side of the ankylosis. Whatever disorders the equal balance of the "couple of forces" produced by the downward pressure of the body weight at the sacro-iliac joint, and the upward pressure of the heads of the femora (which normally falls outside the line of action of the body weight) on each side, tends to a progressively increasing disorder of the balance of the two sides, as Dr. Galabin had just remarked, and as he had himself set forth in the paper alluded to. Moreover, as he had there explained, the overweighted side is naturally the side of the greater muscular action, including increased pressure of the femora and increased muscular and therefore osseous nutrition. To Dr. Galabin and also to Dr. Herman he would say that in his paper he endeavoured to prove (1) that the action of gravity must tend to evert the distal end of the iliac beam (this being directly contrary to the accepted view); (2) that the "inward pressure of the femora," which undoubtedly exists in the malacosteon and other pelves, could not be due to this action, but could only be accounted for by the action of muscles. As to the question whether outward or inward pressure predominated, he was not at present prepared either to agree or disagree with Dr. Galabin. No doubt in a softened pelvis inward pressure eventually predominated, but he thought more than one explanation was possible.—Dr. WALTER GRIFFITH said that until the question as to the cause of the sacro-iliac ankylosis was settled, the effects of it were but to be guessed at. He referred to a case of oblique deformity, described by Mr. Sinclair in the *Dublin Medical Journal* for 1855 as being exactly like those described by Naegele, and due to disease of the joint in childhood. The study of four pelves with extroversion of the bladder showed great differences as regards the shape of the pelvis. Cases of extreme scoliosis were found with little or no obliquity of the pelvis. He asked how it was, according to the explanation given by previous speakers, that the pressure of the femora stopped short when the side of the pelvis was straight and when it ought to act at the greatest advantage. He believed that the whole deformity was congenital.—Dr. HERMAN, in reply, did not think that the fact of ankylosis of the sacro-iliac joint would affect the shape of the part of the ilium between that joint and the acetabulum. His grounds for rejecting Dr. Duncan's theory of the Naegele pelvis were that ankylosis was found without the oblique deformity and the deformity without ankylosis, and that the degree of obliquity was proportionate to the degree of lateral dwarfing of the sacrum. He differed from Drs. Galabin and Champneys in thinking that no comparison could be drawn between the Naegele and the scoliotic and malacosteon pelves, on account of the softening of the bones present in the two latter. He thought that the effects of use and disuse of a limb and of vascular supply were comparatively small.

Dr. BRAITHWAITE read a paper on a case of Gastrotomy for Extra-uterine Gestation, in which the placenta never came away. In this case a full-grown fœtus, which had been dead about three weeks, was removed from the abdominal cavity. The placenta fitted on the uterus like a cap, and spread posteriorly on to the neighbouring parts. The operation was done aseptically, and the wound closed except at its lower part, where the funis was left hanging out. The recovery was perfect, though slow. The placenta never came away, except a morsel about twenty grains in weight on the sixth day. The placenta must have been slowly absorbed, and in this the case is unique.—Mr. THORNTON referred to the extraordinary description, and asked Dr. Braithwaite if some mass representing the atrophied placenta were not still to be detected. He had shown to the Society a placenta undergoing remarkable changes after a similar operation, but its condition was by no means suggestive of atrophy.—Dr. BRAXTON HICKS remarked that, whether the placenta had been absorbed or encysted, the fact was of much importance, for he had for some time thought that it would be best to treat the wound antiseptically and close it, leaving in a drainage-tube. In four of six cases on which he had operated, however, the sac was already putrid.—Dr. CHAMPNEYS thought that Dr. Braithwaite only meant that the placenta had not come away, and in this respect his title was more cautious than his description; it might quite possibly have grown in its site, receiving progressive nutrition. He intended, when occasion offered, to strip off the amnion if possible from the interior of the sac and to wash out the vessels of the funis with boroglyceride; this would be a powerful aid to prevent sepsis and could do no harm if absorbed.—Dr. GRAILY HEWITT believed that the placenta might disappear. The vascular connexion was very intimate, and it would probably shrink up and be for the most part absorbed.

MIDLAND MEDICAL SOCIETY.

A MEETING of this Society was held on January 20th, Dr. Holmes Joy, President, in the chair.

Mr. Furneaux Jordan's Operation for Naso-pharyngeal Growths.—Mr. WALTER FOWLER showed a boy, aged sixteen, who had been subjected to this operation. When he was first seen there were symptoms of nasal polypus; this was removed by a snare, and found on examination to be an alveolar sarcoma. It recurred at once, and after a month's interval Mr. Fowler completely removed the growth by dividing the upper lip and the nose on one side of the septum and turning this flap outwards, so as to thoroughly expose the nasal cavity, in the manner adopted by Mr. Furneaux Jordan. The line of cicatrix was hardly visible.

Ophthalmoplegia Externa cured by Iodide of Potassium.—Dr. SUCKLING showed a man, aged sixty-seven, who had been sent to him in November last by Mr. Wood White, suffering from paresis of the muscles supplied by the third nerve on the right side, and total paralysis of those supplied by the third and sixth nerves on the left. The pupils were a little dilated, the left one the larger, and responded to light and accommodation; there were no changes in either fundus. The knee-jerk was present, and there was no history of syphilis or rheumatism. The patient attributed his illness to the cold weather, to which he had been much exposed. Five weeks after Dr. Suckling saw him, he had, after exposure, conjunctivitis of the left eye followed by dropping first of the left and then of the right upper lid. The patient was treated with large doses of iodide of

Digitized by Google

potassium (thirty-six grains thrice daily); he rapidly improved, and had now completely recovered.

Case of Athetosis.—Dr. SIMON showed a woman, aged twenty-four, who had left hemiplegia when two years of age. At seven she began to walk, and it was noticed that she had rhythmical contractions of the fingers of the left hand, as well as talipes equino-varus on the same side. The movements have continued ever since, though she has been told they cease during sleep. The arm is shorter than the healthy one, but there is marked muscular hypertrophy due to the excessive movements.

Some Injuries and Malformations of the Urethra.—Mr. THOMAS read a paper on the above subject. It was illustrated by the histories of various cases which had come under the author's care, and a considerable portion of it was devoted to extravasation of urine in boys, four cases of which were related.

Dr. MALINS showed the following specimens:—1. An iron hammer-head, weighing 5 oz., removed from the vagina of a girl aged fourteen. 2. Cystic ovaries taken from a patient aged thirty-three, weighing respectively 6½ drs. and 5½ drs. 3. Fibroid polypus, weighing nearly 8 oz., removed from a patient aged forty-six. The cervix was divided antero-posteriorly by the thermo-cautery a fortnight previously, and the tumour removed by the écraseur and extracted by midwifery forceps. Before admission to the hospital she had been in bed two years and four months. At the present time she is practically well.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

THE fourth monthly meeting for the session of the above Society was held in the library of the Newcastle-on-Tyne Infirmary, on Thursday, Jan. 21st, Dr. Fielden, President, in the chair.

Aneurysm of the Right Subclavian Artery.—Mr. PAGE showed a girl, aged twenty-one years, sent to him alleged to be suffering from Aneurysm of the Right Subclavian Artery. On careful examination Mr. Page found that there was no aneurysm, but that the vessel was raised over an exostosis growing from the transverse process of one of the cervical vertebræ. This condition was proved by the fact that when the girl stood upright the radial pulse on the affected side was arrested by the stretching of the vessel over the growth. The pulse returned at once whenever she assumed the recumbent position. The vessel could also be slipped forward over the growth. The condition was a very rare one, and excited considerable interest. As the girl was in good health and had no urgent symptoms, no operative measures were proposed.

Loose Cartilage.—Mr. PAGE also exhibited a loose cartilage, 2½ in. long, 1½ in. broad, and ½ in. thick, removed from the knee-joint of an old woman aged eighty. The patient did well.

Leucocythæmia.—Dr. LIMONT exhibited a very large example of uterine myoma and a spleen from a case of leucocythæmia. In the latter there was no alteration in the red corpuscles, but the white corpuscles were very much increased in number. No examination was made of the bone or bone marrow.

Dr. LIMONT also exhibited a specimen of Acute Ulceration of the Colon.

Gastrostomy.—Dr. PHILIPSON showed the stomach and œsophagus from a patient on whom gastrostomy had been performed for malignant disease of the œsophagus and cardiac end of the stomach. The patient lived for three weeks after the operation. The case produced an interesting discussion on the difficulties sometimes encountered in the diagnosis of malignant disease of the œsophagus, and also in regard to the benefits derived from operation.—Dr. HUME believed that the operation of gastrostomy was one which would ultimately be abandoned in cases of cancer.

Uterine Myoma.—Dr. HUME exhibited the tubes and ovaries removed from a woman the subject of a uterine myoma of very large size. The woman made a capital recovery, and at the last examination the operator was of opinion that the tumour was reduced in size. No menstrual flow had taken place since the operation, and there had not been discharge of any kind.

Renal Calculi.—Dr. MURPHY showed two kidneys, the pelves of which contained a large number of renal calculi. The specimens were removed from a boy, the subject of a compound comminuted fracture of the femur, who had passed several calculi during life. In connexion with the case Dr. Murphy also exhibited a series of calculi, all either passed by, or removed from, patients who had sustained fractures of the femur.

Obstruction from Gall-stone.—Dr. MORRIS read a paper on a fatal case of obstruction of the intestine from gall-stone, and a fatal case of perforating ulcer of the small intestine. The gall-stone in the first case was the size of a walnut, and had become impacted in the small intestine, a short distance below the orifice of the common bile duct. In the second case the chief interest lay in the entire want of symptoms of perforation. There was no pain and no very sudden collapse.

Dr. JAMES DRUMMOND read a short note on a case of Intestinal Calculus.

Antisepticism.—Mr. PAGE submitted the results of major amputations treated antiseptically in the Newcastle-on-Tyne Infirmary during the year 1885. From this statement it appeared that during the year there were performed fifty-one major amputations, with two deaths (3·9 per cent.). Of the hip-joint, there were three amputations for disease, with one death; thigh, one for injury, not fatal, and twelve for disease, with one death; knee-joint, one for injury, not fatal; leg, one for injury and five for disease, with no deaths; ankle-joint, two for injury and nine for disease, and no deaths; shoulder-joint, one for disease, not fatal; arm, three for injury and one for disease, with no deaths; forearm, five for injury and six for disease, and no deaths; wrist-joint, one for injury, not fatal. Adding the amputations of 1855 to those of 1884 and 1883, there is a total of 156 major amputations, with eight deaths (5·1 per cent.).

WOLVERHAMPTON AND DISTRICT MEDICAL SOCIETY.

A MEETING of the above Society was held on Thursday, Jan. 7th, Dr. S. A. Smith, in the chair.

Medical Consultations.—The discussion on this subject, adjourned from the previous meeting, was concluded after several members had spoken.

Simple Fracture of the Patella.—Mr. VINCENT JACKSON exhibited two patients who had suffered Simple Fracture of the Left Patella, and in each case the fracture had occurred twice. 1. A gentleman, aged forty-eight, was seen by Mr. Jackson seven years ago on account of a simple transverse fracture of the left patella. The treatment consisted in apposing the fragments and extending the limb on a back splint, with a foot-piece; this was continued until the union (fibrous) permitted progression, and the gentleman resumed his avocation. Six months afterwards he tripped and fell from the top to the bottom of some stairs, refracturing the patella. The treatment was repeated, and the same favourable results followed. 2. The patient, a man twenty-one years of age, was admitted into the hospital with a simple fracture of the left patella. Two days after, when seen by Mr. Jackson, it was determined to wire the fragments together, and for this purpose ether was administered, and when the patient was almost anæsthetised, respiration stopped, and a very alarming condition ensued; fortunately, the means used to restore animation were successful. Mr. Jackson decided not to perform the operation, and directed that the fracture should be treated in the ordinary way, the result being perfectly successful. Two years after his discharge he fell again and refractured the patella. Treatment was for the second time employed, and in the course of time he went home and resumed his work. Mr. Jackson, in a few observations, stated that he exhibited these patients as evidence, if any were wanted, that the wiring of the fragments together in fractured patella was not necessary. Mr. Jackson showed a patella he had removed from a male patient who many years before his death had sustained a transverse fracture of this bone. This specimen was exhibited as an example of bony union which occasionally follows when similar treatment to that already mentioned is employed for these injuries.

Radical Cure of Hernia.—Mr. JACKSON also exhibited a man, aged twenty-four, sent to him by Mr. Clendinnen of Coseley, to be radically cured of a large hernial tumour of

Digitized by Google

the left side, the circumference of which was twelve inches, and its extent downwards seven inches. The hernia was readily reducible, and could be retained within the abdomen by a truss, but as the man wished to be relieved of the disagreeableness of wearing such an instrument, he readily submitted, seven weeks since, to the necessary operative treatment. No truss is now worn, the external ring and the inguinal canal being completely obliterated.

DEVONPORT AND PLYMOUTH MEDICAL SOCIETY.

Exhibition of Cases and Specimens.

THIS Society held its first monthly meeting at Plymouth on the 27th ult., when demonstrations of the distinguishing features in a series of spinal nerve lesions were given by exhibitors of cases.

Dr. C. ALDRIDGE (Plympton) showed a typical case of Tabes Dorsalis associated with Ophthalmoplegia Externa; also a case with anomalous symptoms.

Dr. A. H. BAMPTON (Plymouth) showed and compared a case of Infantile Paralysis with two cases of Progressive Muscular Atrophy; one of the latter with a history of long-continued masturbation; the other of obscure origin.

Mr. A. BUCHAN exhibited a case of Lateral Sclerosis and Iritis, rapidly improving under specific treatment.

Fleet Surgeon ASTLEY COOPER, R.N., brought forward a pathological specimen showing Perforation of the Duodenum occurring in a sailor, with a healthy history, after a drinking bout of beer.

Mr. G. JACKSON (the President) showed a Malignant Growth of the Head of the Humerus of a youth after slight injury; also, a pathological specimen of Cancer of Omentum, weighing several pounds, taken from a patient who pursued a laborious occupation up to a few days of his death from peritonitis.

Mr. B. W. MURLAY narrated cases of Colles Fracture treatd with Carr's splint, giving excellent results.

Reviews and Notices of Books.

The Blot upon the Brain: Studies in History and Physiology. By WILLIAM W. IRELAND, M.D.Edin., Corresponding Member of the Psychiatric Society of St. Petersburg, &c. Pp. 374. Edinburgh: Bell and Bradfute.

The volume before us, whether regarded as an exposition of mental science or an historical sketch of the mental obliquity betrayed by many great ones of the past who have left their "footprints on the sands of time," will find many enthusiastic admirers, and serve at the same time to instruct and interest the thoughtful reader.

Dr. Ireland, always a cautious and painstaking student of life and character, has given us a lucid exposition of some of the most difficult problems in mental philosophy, and, what is more, he has succeeded in translating his ideas in graceful and eloquent language. It is not often that one meets with a book treating of a difficult, and we might say indeterminate subject, so cleverly constructed, and illustrated by facts gleaned from the world's history. The opening paper treats of "Hallucinations, especially of the Sight and Hearing." The second and third are devoted to the consideration of the hallucinations betrayed by such interesting characters as Mohammed, Luther, Swedenborg, and Joan of Arc. A perusal of these studies will enable the reader to grasp more fully the nature of the "ruling passion" possessed by those who have come under the author's contemplation and review. "Insanity of Power" is worked out in three chapters. After discussing the questions of the "Limitation of Life" and the "Debasing Effects of Unchecked Power," the writer follows up his train of thought and reasoning by reference to episodes in the lives of several Roman emperors, Mohammed, Toghlak, and the autocratic rulers of Russia.

Possibly the chapter on the "Hereditary Neuroses of the Royal Family of Spain" will be the one that will find most admirers. No more complete demonstration of the numerous ways in which hereditary neurosis may manifest itself could be imagined than is contained in the description, pathological and historical, here referred to. It is shown how in one the want of mental equilibrium was portrayed by turbulent passion, such as was evinced by our own Henry VIII., who is said to have been tetchy and wayward in infancy; desperate, wild, and furious in youth; daring, bold, and venturous in manhood; and subtle, sly, and bloody in age; and in another by the absence of judgment, and power to regulate the ordinary duties and courses of life. After a complete, though somewhat tiring narrative of the history of St. Francis Xavier, the Apostle of the Indies, the author again betakes himself to the analysis of certain problems in mental pathology. Thus in succession we have an account of "Fixed Ideas," "Folie à Deux," "Unconscious Cerebration," "Thoughts without Words, and the relation of Words to Thoughts," "Left- and Right-handedness," "Mirror Writing," and lastly of the "Dual Functions of the Middle Brain." Our limited space prevents a full discussion of the merits evinced by the author in the treatment of these difficult and contested "points." To those who desire the pleasure derivable from the perusal of a work learned and interesting we heartily recommend Dr. Ireland's book.

Rome in Winter and the Tuscan Hills in Summer: a Contribution to the Climatology of Italy. By DAVID YOUNG, M.D., &c., late Professor of Medical Botany in the Grant Medical College, Bombay. Pp. xv.—283. London: H. K. Lewis. 1885.

SOME fifteen years' professional work among his compatriots in Central Italy has enabled Dr. Young to write with intelligence and authority on the health aspects of residence in Florence and Rome. His own experience he has supplemented by diligent study of Italian fellow-workers in the same field, and the result is the little volume before us—an able contribution to a subject systematically treated by no English physician since Sir James Clark's publication half a century ago.

A book of the kind was needed, for, of all the centres of attraction for the travelling Englishman, Rome, by the testimony of successive generations of practitioners within her gates, is, as a winter residence, the least understood and the most misrepresented. Of the 18,000 English-speaking visitors that resort to her annually, the vast majority return in every way the better for their sojourn, with a desire to revisit her all the stronger the more time they have had to give her. "Rome," says an eminent German physician, "would be the healthiest of capitals if she were not Rome"—if she were not, that is to say, an agglomeration of ruins, catacombs, draughty basilicas, and ice-cold halls of marble, into which the art-votary or historic enthusiast plunges in all weathers and conditions of body, eager to crowd as much as possible into the twelve hours, especially if his time is limited (as it too often is) to a few days. The practitioner who knows how the Englishman abroad disdains precaution, and how in Rome he so frequently makes himself a candidate for whatever hygienic harm is to be encountered, can only marvel that the victims to the Dea Febris are so very few. In his third chapter Dr. Young puts it beyond question that out of London there is no city in Europe where his compatriots are less likely to contract typhoid than in Rome; and he might have added that in no other European city does the English resident who suits his life to his surroundings arrive at greater longevity.

Having shown how risks are best to be avoided in Rome, Dr. Young leads up by a careful induction of climatic and

Digitized by Google

hygienic conditions, to the cases for which a winter residence in the city is specially indicated. All that he has to say on the malaria, the water-supply, and the improved drainage will have little novelty for our readers, compiled as it is from authorities frequently quoted in these columns; but his *catena* of cases, in which observance or violation of the maxims he lays down has been rewarded or punished by improved or impaired health, is exceedingly interesting as deduced from the experience of an extensive *clientèle*. He has disappointed us, however, under the section of "Cases Suitable and Unsuitable for Rome," by the scantiness of his references to a class of visitors increasingly numerous in the Eternal City—the Anglo-Indian officer, combatant or civilian, who having contracted the malarial cachexia in one or other of the Presidencies, requires special rules for guidence when wintering in Rome. His own Indian experience entitled us to expect a fuller consideration of this part of his subject.

As to his style, let us say at once that Dr. Young writes with clearness, facility, and force, and that when called upon, as in the descriptive chapters on the Alban and Sabina Uplands and the Tuscan Hills, he can rise with his theme. But too frequently he disturbs us with "pleonasm" and "anacoluth," and we have now and again to readjust his punctuation to give the sentence a main verb. These marks of haste, we trust, will be removed in an early edition.

Bericht über die Allgemeine deutsche Ausstellung auf dem Gebiete der Hygiene und des Rettungswesens. Herausgegeben von Dr. PAUL BOERNER. I. Band. Berlin. 1882-3. Breslau: S. Schottlaender. 1885.

AMONGST the numerous services rendered to the cause of medical and social science by the late Dr. Paul Boerner, few demand such recognition as the work he undertook in connexion with the great Hygienic Exhibition, which was held in Berlin two years ago. Dr. Boerner was indefatigable in promoting the objects and assuring the success of that Exhibition, and to him accordingly was allotted the duty of supervising the records, of which the first volume is before us. The editor himself contributes but little to the work beyond the introductory chapter, which relates the steps taken to found the Exhibition, the destruction of the first building on the eve of its opening in 1882, and the manner in which the second and better constructed building was completed and equipped within the ensuing twelve months, the opening ceremony, and the lectures &c. delivered during the progress of the Exhibition. These are the matters which are discussed in the opening pages. The bulk of the volume consists of a series of articles upon the several departments, each being written by acknowledged authorities, and the result is a work of permanent interest and utility. Thus we have described by Drs. Sell and Löffler the laboratory of the Imperial Board of Health, a fully equipped pavilion in the grounds being one of the features of the Exhibition, where demonstrations were daily given. The methods of research upon micro-organisms are detailed, as well as the process of analysis of foods, &c., which belong to this institute. The various apparatus employed in hygienic research is described by Drs. Wolffhügel and Fritsch and Professor Gruner; meteorological instruments by Dr. Löwenherz. Very useful articles upon foods and articles of diet are contributed by Drs. König and Sell, including the methods of preparation and the composition of the more common articles. The hygiene of infancy and that of schools are discussed by Drs. A. Baginsky and S. Guttmann, especial attention being paid to the dietetics of infancy and the composition of artificial foods. Considerable space is allotted to an article upon boots by Herr Beely, the importance of which is hardly sufficiently recognised by the community. The writer enters into full detail respecting the best construction of these articles of clothing, in accordance with anatomical facts. Baths and bathing institutes are assigned to Dr. Lassar, under whose auspices a cheap public bath was open to the visitors to the Exhibition. Workhouses, prisons, reformatories, model dwellings, barracks, &c., form other subjects written upon by Herrn Albrecht, Volkmann, and Kuhn, and illustrated by numerous drawings and plans. The whole forms a handsome, well-printed, and fully illustrated volume, which will be much appreciated by all who take any interest in the advance of sanitary science.

Nouvelles Archives d'Obstétrique et de Gynécologie.

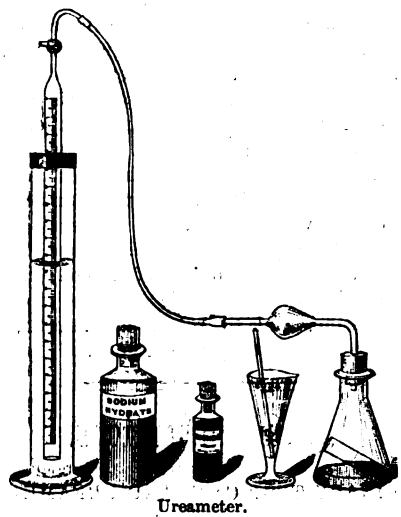
WE have received the first number of this publication. It is issued under the direction of Charpentier, Duplay, Bernutz, Guéniot, and others, Doléris being the chief editor. The present number contains four original papers. The first is by Charpentier, on the Persistence of the Hymen as a cause of Dystocia. Another is by Doléris, on Shortening of the Round Ligaments. The third paper is on Twin Pregnancy, by Verrier; one twin was well developed, the other papyraceous. The fourth paper is on Uterine Dilatation, by Betrix. The rest of the number contains a summary of the work of Societies and work done abroad. There is room for a good obstetrical journal, for there are plenty of bad ones. The object of a good journal at the present time should be to guide and not to follow; to publish scientific, and to reject unscientific, work; to destroy the bad by multiplying the good.

New Inventions.

URINARY TEST CASE AND UREAMETER.

RECENT observations made in THE LANCET induce me to bring prominently before the profession a urinary test-case specially constructed, and a ureameter. Both cases were made for me by Mr. Hume, Scientific Instrument Maker, 1, Lothian-street, Edinburgh, the price of the test-case being 5*s.* 3*d.*, and of the ureameter, packed in case, 18*s.*

Last winter I instituted a series of comparative estimates of the value of the various new urinary tests with the older



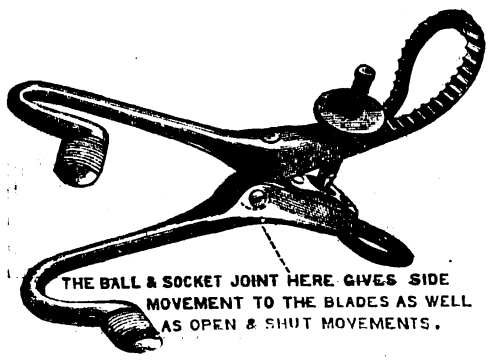
Urinary test-case.

and better known ones, and I came to the conclusion, without any preconceived opinion, that the older tests were more accurate and less liable to be misunderstood, and on these two cardinal points were superior to Oliver's tablets or Picric acid. The difficulty in competing with their new rivals was the non-portability in a cheap form of the various liquid reagents necessary for testing the urine. This consideration has been solved by the handsome, safe, and compact case of

Digitized by Google

Mr. Hume. Nitric acid, Fehling's solution, and alcohol are secured in well-stoppered bottles; and the case is also provided with litmus-paper, test-tubes, and a small cup in which spirit can be poured and, after lighting, heat can be applied to the urine in a test-tube. The accompanying engraving will give a good idea of the urinary test-case.

The ureameter has been considerably altered from the one I suggested in 1880. Defects have been remedied, the tubing has been made to fit so exactly that there is no chance of the liberated gas escaping, the form of the bottles has been changed, and the means, as a whole, rendered easier of application. The accompanying engraving gives an excellent idea of the form of the instrument and the reagents



Ureameter.

employed. There is no doubt that the detection of the daily excretion of urea is of great importance in the treatment of diseases, and bears largely on the prognosis of chronic Bright's disease, acute rheumatism, and gout. More accurate treatment can, by the estimation of the urea, be adopted. This ureameter is easily worked. It gives perfectly accurate results, and the daily testing may be done by an experienced nurse at the patient's house, and the result noted with the temperature-chart and other details of the sick room.

MATTHEW CHARTERIS, M.D.,
Professor of Therapeutics and Materia Medica, Glasgow University.

MASON'S GAG.

THE accompanying illustration represents a modification which Mr. Francis Mason has had made in his well-known Gag, which was first introduced to the notice of the profession in 1871. The improvement consists in the addition of a small ball-and-socket joint, by which a slight

universal movement is provided. It will be the experience of most surgeons that in children, and even in adults, the teeth are often brittle or loose, and that in using the ordinary gag they are apt to get either broken or displaced. The instrument above depicted, whilst still retaining the lower jaw in firm position, yet allows it just sufficient movement to obviate such accidents. Moreover, it is small, being about four inches in length, and yet is of such strength as to meet all the requirements in operation on the mouth of the most robust and muscular subjects. Messrs. Matthews Brothers, of Carey-street, Lincoln's-inn, are the makers.

THE "VISCOUNT" VENTILATING SHOOTING AND MILITARY BOOT.

THIS boot is the invention of Mr. J. Morgan of Frome. Royal letters patent have been allowed him for the following novelties connected with its construction. It is waterproof, but not air-tight. This great desideratum, and apparently contradictory condition, is attained by the introduction of ventilating air-tubes passing behind the ankles to permanent outlets on either side of the boot. The act of walking causes a pumping action, thus a current of fresh air is drawn through the boot. By this means the feet are kept dry, and at the same time free from the perspiration from which so many persons suffer, and which is not only an annoyance and impediment to exercise, but a prolific cause of chills and colds. This boot can be put on and taken off with great rapidity, for lacing, unlacing, and tying are done away with, the "lacing" being very ingeniously effected by simply drawing the lace tight, passing it two or three times round the ankle, and inserting it through a patent "grip catch," which holds it effectually. The boots are manufactured as ordinary walking, shooting, and military boots, and from our own experience we can state that they are both healthy and convenient; the last variety, considering the above description of their construction, seems to be well worthy of the attention of the authorities at the War Office.

ARMY MEDICAL SCHOOL, NETLEY.

THE prizes gained during the last session by the students in connexion with the Army Medical School, Royal Victoria Hospital, Netley, were distributed on the 1st inst. by Dr. Quain, in the presence of a large assembly. Previously to the distribution, Professor Longmore read a list of the awards, and after the ceremony,

Sir T. Crawford congratulated the successful students on having gained their commissions. He remarked that the army was different from the civil profession in this—that when his hearers left that school they were charged with all the duties of a medical man. There are no specialists in the army. There is no opportunity of taking counsel with the heads of the profession when they had to deal with the lives of those in the field. It would therefore be necessary for them to continue their habits of study, and he expressed a hope that when they arrived at his age they would be able to look back and thank God that they had done their duty. Sir T. Crawford concluded by moving a vote of thanks to Dr. Quain.

Sir J. Fayrer, in seconding the vote of thanks, also congratulated the students on their success, and expressed the hope that they were entering upon a long, brilliant, and successful career. He said that they had a great future before them in the greatest service in the world, for such he considered the British and Indian Medical Service, and he felt certain that they would do justice to it. He entreated them when they went abroad to go with open and free minds, to see and search for themselves, to study facts, to watch carefully, to be observant, and, above all, not to force facts to fit theories. It was more necessary than ever to be careful and watch for themselves, and never come to hasty conclusions.

Professor Longmore afterwards briefly addressed the students, after which the proceedings terminated.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 6, 1886.

WE cannot congratulate Mr. MACNAMARA on his letter which we published last week; it is not likely to add weight to his position as a member of Council. Were it needed, it is another proof that the possession of the Fellowship does not necessarily carry with it the logical mind and special business capacity such as are claimed for the holders of this diploma by admitting them alone to a voice in College management. The letter is a weak plea for the *status quo* as regards the Members, the chief argument why Fellows alone should vote and sit in Council being "in order to promote and encourage the practice of surgery," and "that the College should continue to have the power to confer honours in surgery."

Mr. MACNAMARA tells us that a very large proportion of the Fellows are in general practice, and he thinks that the interests of the Members could be looked after by sending these Fellows to the Council. He elsewhere in the letter tells us, in the words of the Charter, that "it was in order more effectually to promote and encourage the study and practice of surgery that the class of Fellows by examination was instituted." Now "general practice" is honourable in every way; but can anyone reasonably argue that general practice tends *more effectually* to promote the study and practice of pure surgery? Does not the fact that so many of the Fellows are in general practice itself show that the objects for which the Fellowship was founded have been carried out very imperfectly indeed? On the other hand, are there any facts to show that Fellows make better general practitioners than Members? and unless they do, on what grounds would Mr. MACNAMARA make the one representative of the other on the Council? We must nevertheless thank him for the admission conveyed in his proposal that the Members ought to be represented. We wait in vain for substantial reasons why Members should not sit on the Council. The arguments *unanimously* agreed to and set forth by the Council, and presented to the last general meeting at the College, were specious and too frivolous to be considered, and were more than met by Mr. HOLMES's philosophical reply. Failing the Council itself, we have looked among the Fellows at large for some reasonably logical arguments against granting the full franchise to Members, and as yet in vain.

Mr. MACNAMARA, however, has introduced a new element into the discussion. While unable to bring any positive evidence against the fitness of Members for the Council, he tries to show that "by only permitting Fellows to be elected to the Council it is possible that we enhance the position of the Fellowship, and so may lead men to seek the Fellowship, and thus forward the objects for which the College was founded." This is the last straw. The Fellowship is to be enhanced at the expense of the Membership, the leading object for which "the class of Fellows by examination was instituted"—the promotion of the study of surgery—is to be accomplished by excluding the Members from all voice in the management of the College, which their work and their fees have made what it is! It is well for the Members to know how matters really stand, and the use to which Mr. MACNAMARA would put them.

Seriously, the Members must bestir themselves; it is quite obvious that they will get very little from the present Council. What with delays and adjournments, the determined opposition of some members of Council, the half-hearted support of a few, and the want of administrative capacity in others, the Members stand a poor chance of being restored to the position they occupied prior to the institution "of the class of Fellows." We have pointed out over and over again, without any effect, the advantages which would accrue to the College, the gain it would be to the profession at large, the cohesion it would give to the scattered Members, and the political power that would ensue, from their enfranchisement. The real function of the College of Surgeons is to supply the country with general practitioners; and the union lately effected with the College of Physicians for this purpose is a wise one, and shows that the Council have recently realised this fact and that they are acting on it. The Fellowship is a something superadded. Its object is to provide a certain number of hospital surgeons—men who teach and practice surgery entirely. This diploma, therefore, is a special scholastic distinction, and should only be attainable by those who devote themselves to pure surgery; it ought never to have conferred any special political rights, and never would have done so had those who instituted it thought more of the promotion of the study of surgery and less of their own personal aggrandisement. The Members must rouse themselves, and if the Council continues to ignore their just claim, an independent effort must be made to secure those changes in the Charter which, endorsed by the Association of Fellows, and, as their mouthpiece, Mr. HOLMES claimed at the meeting lately held at the College.

We may reasonably ask whether the time has not come when the Council—whatever its composition may ultimately be—should be strictly representative? The affairs of this country are carried on by a representative Parliament; why should not the College be governed in the same way? Our readers will remember the indignant protest which a present member of Council addressed to us some time ago because the Association of Fellows had ventured to sound him as to his views on College matters. Ministers of the Crown see nothing derogatory to their dignity in being thus questioned. The public expression of a man's views on current College policy previously to his election would enable voters to select those who showed themselves most conversant with such matters, and it would ensure for the Council men who had taken the trouble to make themselves familiar with the objects on which they would be called upon to speak and vote if elected.

WITHOUT committing ourselves to an acceptance in full of the pictures which Dr. ROBSON ROOSE has painted in the *Fortnightly* of the routine lives of barristers, judges, physicians and surgeons, Cabinet ministers, and ordinary members of Parliament, in some of which the

Digitized by Google

outlines are too vague and the details inadequate, there can be no question as to the fact that life in London does involve a special amount of wear and tear not sufficiently recognised. It is true that "every age is characterised by the presence or prevalence of special disorders of health which have a more or less obvious causation," and the "wear and tear" on which the above-named author descants are undoubtedly causes of disorders of health which characterise the present age so far as the health of the particular classes to which he alludes is concerned. We may go further, and admit that what we suppose to be implied by the not very precise term "want of tone" is the—or it may be better to say *a*—characteristic feature of disorders in general just now, and that "in none is it more obvious than in those which peculiarly affect official and professional men working at high pressure." What we understand by "want of tone," so far as any precise meaning can be attached to the phrase, is the inertia of exhaustion. There are many varieties of inertia or lack of potential energy arising from different faults in the organisation or working of the brain and body. And there may be want of power from some fundamental organic defect which renders the evolution of force impossible. In this case the result will take the form of incapacity rather than "want of tone." We cannot but think that no inconsiderable proportion of the disorders which the writer of the paper would appear to attribute to the effect of undue "wear and tear" should rather be ascribed to the natural incapacity of men, and women too, who, without a physical organism capable of evolving force sufficient for the needs of the lives their ambition impels them to try to lead, place themselves in situations calling for more power than they can possibly evolve in response to the requirements of an unsuitable environment. It must never be forgotten that—whatever view may be taken as to the existence of a soul inhabiting the body—*mind*, properly so called, is simply and solely brain-function; and in working the brain mentally we are doing a precisely similar thing to working the muscular system by locomotive exercise, or the digestive and nutritive glandular system by eating and drinking so as to necessitate activity of the assimilative and disassimilative apparatus. The one process is as directly and purely physical as the others. Excessive thought means cerebral hyperæmia as inevitably as excess in the use of a gastric stimulant means active congestion of the mucous membrane of the stomach; and just as habitual excessive use of too irritating food and drink may induce passive congestion in the intervals, or as the sequel, of active congestion of the gastric organ, so may too persistent and excessive brain work tend to the production of a chronic engorgement of the vessels of the encephalon, with whatever that physical fact involves or entails. We speak of only *one* form of disorder which may be induced by excess of brain work, not to the exclusion of others, but simply by way of illustration. The point on which we wish to insist is that a perfect similarity of law governs the development of disorders of brain and body; and, as a consequence of this indisputable proposition, it must be understood that just as some individuals have a natural congenital incapacity for great muscular exercise or excessive efforts of digestion or disassimilation, so certain persons have a natural congenital inability for considerable or prolonged brain work; and these persons are almost sure to break down ultimately, although they may be propped up for a time by stimulants and other temporary aids to exertion, if they persist in undertaking mental work which is too great for them. The inability of which we speak does not necessarily imply any want of intelligence, or even of cleverness. On the contrary, it not uncommonly happens that the men and women who are unfitted by nature for continuous exertion of the mind are capable of exceptionally brilliant exploits of intellectual energy, which resemble the sudden discharges of a leaky accumulator overcharged with electricity. Such persons are in danger of being betrayed into false positions by the misleading effect of sudden successes, and the too impulsive appreciation of those with whom they are brought into contact. Many a signal collapse in statesmanship, in literature, in science, in art, and in many other walks of life may be explained in this way, and we believe ought to be so regarded, rather than as the result of overwork or fair wear and tear even in London life. There is far more over-reaching than over-working in this modern life of ours. Success is too generally accepted as a conclusive proof of capacity, instead of being attributed, in part at least, to the chapter of accidents. Those who wait on the development of character, and study the evolution of organism and force through long periods, know that the plant which springs up and bears fruit quickly has too often no deep root. An explosive liberation of energy is far more likely to take place in the prematurely energised than in the slowly and steadily growing organ.

We quite agree with Dr. ROOSE as to the importance of mending the fashion of the time as regards work and enterprise; and, subject to certain reservations which it is necessary to make, we are willing to concede that "progress" may be too rapid. It is just as foolish to haste to be great and successful as it is to haste to be rich; but looking at these matters from a practical point of view, we cannot help thinking the medical practitioner may accomplish the largest amount of real good by warning those with whom he comes in contact against the over-estimation and undue strain of limited capabilities. It is not for the interest of the race or of the individual happiness of mankind, and particularly the English community at this epoch of our national history, that every young man and young woman who evinces a little capacity or shows "cleverness" should be encouraged and incited to make efforts which demand not simply an accumulation but a reserve of energy, and, what is even more important still, the physical capacity for producing force, almost indefinitely, to replace that which is called out by exceptionally exigent circumstances. The times in which our lot is cast, and the life we are called upon to live, demand powers of endurance and a productive capacity for the evolution of energy such as, perhaps, man has never needed before.

NINE months ago Mr. MITCHELL BANKS related at the Medical Society of London a case of strangulated scrotal hernia, in which, on opening the sac, he found several inches of gangrenous intestine. The sphacelated bowel was excised, and the two ends of intestine were united and returned within the abdomen. The patient recovered. This case excited some discussion at the meeting at which

Digitized by Google

it was related, and we commented on it. We find that, within a few days of the reading of this paper, and before a report of it had crossed the Atlantic, a very similar operation was performed in America, and with an equally successful issue. The case is recorded in the current number of the *International Medical Journal*, and was under the care of Dr. CLARK STEWART, of New York. The patient was a man aged sixty-eight, who was admitted to hospital with a strangulated femoral hernia which had been irreducible for three days. On opening the sac, fæcal matter and fluid escaped, and there was then exposed to view a coil of intestine three inches long, "on the convex surface of which was a diverticulum about one inch in diameter, having a small ragged opening at its extremity." The walls of this diverticulum were very thin, as the mucous membrane of the gut was here destroyed, leaving only some peritoneum and dilated veins. About four inches of the bowel were then excised, the corresponding portion of the mesentery being ligatured in segments half an inch from its attachment to the gut. All bleeding vessels in the bowel were tied, and the two ends were then united by fine gut sutures, and the part returned within the abdomen after free irrigation with corrosive sublimate lotion. On the following day the man took three cups of milk; on the third day whisky and sarco-peptones were added to the dietary. On the sixth day one large stool and on the seventh day two natural motions were passed. Subsequently, the patient showed signs of congestion of the base of the left lung, and gave much trouble from active delirium. The wound healed by first intention, and the patient eventually left the hospital quite well.

This case will lend considerable support to the views originally advocated by Mr. MITCHELL BANKS, and will induce surgeons to look with more favour upon a procedure which has provoked a good deal of criticism. The published report of this case is deficient in many particulars. Thus no mention is made of the state of the coil of intestine in the hernia, but only of the diverticulum, except that it is once called "diseased"; and it is only from the heading of the report that we infer it to have been gangrenous. Nor is there any satisfactory mention made of the state of the coverings of the hernial sac. The sequel of the case is also given in a very imperfect manner. In spite of these defects, however, the report is valuable, and suggests one or two points for discussion.

First, as to the advantage of the operation. Dr. STEWART says that out of twenty herniotomies he has seen, gangrenous gut has been found in two instances, and in both the bowel was opened and left *in situ*, "both patients dying early from septicæmia." It was this adverse experience which led him to prefer excision of the intestine when this case presented itself to him. We have little doubt that in this particular instance the right line of practice was followed, for at the time of the operation the patient's pulse was only 80, and we are led to infer that there were no local conditions to render such a proceeding particularly difficult or dangerous. There appears to have been just the combination of local and constitutional conditions which favours recovery after enterectomy. In one particular, however, the principle of the operation differed from the ordinary one, in that it included a V-shaped piece of mesentery, this peritoneal fold was tied and divided close to and parallel with the bowel. The advantage of this plan is that it does not interfere with the blood-supply to the bowel on either side or imperil its vitality. One of the great dangers attending the excision of a V-shaped piece of mesentery is the occurrence of gangrene in the bowel left behind. Where the length of bowel to be removed is not great, the practice pursued by Dr. STEWART is undoubtedly the best; and where a greater length of bowel has to be removed, a combination of the two plans might afford the best results, a small V-shaped piece being removed from the central part of the detached mesentery.

Still more important inquiries are suggested by the subsequent treatment of the patient. Mr. BANKS used every precaution to secure prolonged rest to the bowel, giving only ice for four days, then for eight days more ice and beef-juice, and the bowels were not relieved until the twenty-third day. Dr. STEWART, on the other hand, gave milk after a few hours, and quickly added alcoholic stimulants and liquid food in "large amounts," while the bowels acted on the sixth day. The one case was a man aged twenty-five, the other sixty-eight; but this by no means sufficiently explains or justifies such a wide divergence in practice. We must confess to being strongly of opinion that the plan carried out by Mr. BANKS is the better of the two, for it alone secures that rest to the injured parts which is so important in securing their speedy and firm union, and the prevention of extravasation from the intestine, with subsequent peritonitis. Dr. STEWART'S patient seems to have been a very troublesome one to deal with, and all praise is due to the surgeon for the successful issue of the case, but we believe that if the diet had been more rigorously restricted, and stimulants lessened or withheld altogether, the opiates exhibited would have exerted more power in restraining the peristaltic action of the intestines. That, in spite of all these adverse circumstances, the stitches held, and no fæcal extravasations occurred, is a striking testimony to the skill with which the intestinal suture was made and the rapidity with which peritoneal wounds may heal.

IN entering upon his duties as medical officer of health for the borough of Bradford (Yorks), Dr. HIME takes the opportunity of reviewing the work done by the Corporation during the ten years which have elapsed since the passing of the Public Health Act of 1875. The borough of Bradford covers an area of 10,776 acres, or 16·8 square miles; and in 1884 the population per acre was 19·4; it varied, however, from 100 per acre in the west ward to 2 per acre in Allerton. The population in 1884 numbered 209,564, it having increased to that number from 118,098 in 1864. The birth-rate has varied largely during the decennial period 1875-84. In the earlier part of that period it averaged some 38 per 1000, but it had latterly fallen to but little over 29. In this connexion it should be noted that the proportion of marriages has steadily declined; indeed, whereas every 68 persons in the borough provided one wedding in 1872, it now requires 105 persons to bring about the same result; and it seems evident, from what Dr. HIME says, that other causes than diminution of commercial prosperity must account, in part at least, for this decline in the marriage rate. But if the birth-rate has diminished, there is satisfaction in also noting

Digitized by Google

a very decided diminution in the death-rate, which, with but comparatively insignificant oscillations, has fallen from between 26 and 27 per 1000 in 1865-74 to 21·0 per 1000 during 1875-84, the mean during the last five years of the latter period being only 20 per 1000. This point is illustrated in different ways by Dr. HIME; and a diagram in which the excess over 20 during each of the ten years 1875-84 is shown by means of columns must convey to the most uneducated the lesson that a satisfactory result has been achieved in so far as the saving of life is concerned.

Taking up the question of mortality at different ages, it appears that immediately prior to 1875 the deaths under one year were at the rate of about 20 per 1000 births, whereas during the last five years of the decennium under consideration they had fallen to an annual mean of 166 per 1000, and this notwithstanding a somewhat exceptional excess in 1884. Dealing next with the mortality at school ages, a subject which has recently occupied a good deal of attention, it will be remembered that in 1882 the Registrar-General was able to point out that whilst the general rate of death at the school age had diminished somewhat considerably, there was a very slight increase in the mortality at that age from nervous diseases, and that the rate from tubercular meningitis and hydrocephalus was 0·22 per 1000 during 1881 and 1882, whereas during the ten years 1861-70 it had averaged 0·20. Dr. HIME, examining the statistics for Bradford, points out that whereas in Bradford the decline between the mean rate for the ages of from five to fifteen years between 1875-79 and 1880-84 amounted to 25 per cent., yet there had been an increase amounting to 3 per cent. in the "local diseases," including affections of the brain and nervous system at the school age, and this notwithstanding a diminution of 7 per cent. in this group when all ages are taken into consideration. And taking up several classes of diseases, he shows that between five years and fifteen years the differences between the rates in the periods 1875-79 and 1880-84 were as follows:—Nervous diseases exhibited an increase of 42·5 per 10,000, hydrocephalus showed a diminution of 34·2 per 10,000, and convulsions an increase of 180 per 10,000. As regards the latter rate, however, it is pointed out that its significance is diminished by reason of the small number of deaths occurring from convulsions between five and fifteen years. The outcome of this investigation shows that the very satisfactory improvement which is observable in the various classes of deaths during recent years has not prevailed amongst the "nervous diseases," which at the ages referred to have become more fatal, and this increased fatality at this special period of life is regarded as indicating the bad effects of injurious agency in connexion with schools. At the same time Dr. HIME, whilst pointing to the facts as deserving of the earnest attention of the authorities concerned, gives his opinion that the whole mischief cannot be attributed to schooling alone. In every way the population "lives faster," and this is especially the case amongst children, who are brought forward to an extent not thought of in former years.

Comparing the deaths from the several specific fevers during the two periods of five years forming the decennium 1875-84, it appears that the small-pox rate per 10,000 had fallen from 0·10 to 0·05, scarlet fever from 11·88 to 4·52, diphtheria from 1·03 to 0·49, and the "fevers" from 3·52 to 2·20, whereas there had been an increase as regards measles and whooping-cough; diarrhœa also had slightly increased; but phthisis, and the pulmonary diseases most likely to be confounded with it, had undergone some diminution.

In many respects this report almost resembles a text-book of practical hygiene, as regards such matters as the precautions to be taken against consumption, the history of woolsorter's disease, the notification of infectious diseases, the pathology of the infectious fevers, and the hygiene of factories. In each of these matters the experience of Bradford is given, and the report, as a whole, cannot fail to be of great local value, and to form an admirable introduction to the series of annual reports which we may expect Dr. HIME to prepare.

SIR ANDREW CLARK does not confine himself to the limit of his consulting-room in dispensing good advice. His conception of the function of the physician is a large one. According to it the physician is a public teacher, whose duty it is to enunciate the laws of health, and not to stop there, but, in the style of the old prophets, to threaten the very judgments of heaven to all who break them. The laws of health, according to Sir ANDREW's view, are synonomous with the commandments of GOD, and disease comes of sin, ignorance, and folly. "All men ought to be healthy; men were not made to be diseased," but they rebel against the laws of health, they prefer to take their instincts for their guide, and so they incur disease. Instincts, inclinations, appetites, can never be trusted alone with safety; they must be controlled and guarded by two policemen — experience and understanding. In London, Sir ANDREW said, in his speech, in presiding at the National Health Society, at least half the population are ill from not recognising that mental health depended on the health of the body, and because they would not deny themselves and obey the laws of health. There is something very absolute in these teachings, and some may be disposed to question whether they are not too severe and impracticable. But in the main they are right, and it must be conceded that a very large part of the need for doctors arises from the sins, ignorance, and follies of mankind. Absolute health, indeed, may be unattainable. Many of the longest and the most useful lives do not exemplify it. Women exceed men in their longevity, though they are by no means models of conduct as regards observance of the laws of health. But in the main, we repeat, Sir ANDREW is right, and half the diseases of the world, and especially of our civilisation, will disappear when men have learnt to live "soberly, righteously, and godly." It is amazing to notice the ignorance of the laws of health and the functions of the body displayed by even enlightened people. It is equally so to observe their notions of the possibility and nature of medical help. When Dr. JOHNSON was attacked with paralysis of speech he was very anxious to see Dr. HEBERDEN, and, in a letter containing much sound medical sense, expressed his opinion that much could be done by stimulants, and suggested that "a vomit, vigorous and rough," might rouse the organs of speech. Equally crude are the views that obtain among otherwise educated people nowadays, who are apt to divide their faith between coarse drugs and impalpable doses, and who make the

Digitized by Google

fundamental mistake of supposing that medicine is the great preservative of health, apart from observance of the laws of health. The members of our profession need be in no fear of having no work to do. Their occupation is not likely to go and universal health to prevail, for a few centuries yet. For the present men study everything before their health, and come to the medical man to extricate them from the consequences of their inattention. It would be no unwise thing for people to consult the physician as to the prevention of disease in themselves and their children. But this presupposes that something short of actual disease will make them willing pupils of the physician. This is a somewhat violent supposition, and raises the question whether even the eloquence of Sir ANDREW CLARK will induce men to regard the laws of health until they have to learn their existence from the consequences of breaking them.

LITTLE, if anything, would be gained by discussing the question of lunacy law reform until the Legislature shall have found it possible to make time for at least the most urgent of ordinary business in the interests of domestic peace and prosperity. At present the attention of the governing authority seems to be monopolised by matters of no moment to the masses of the people, and meanwhile the real needs of the community wait. This is a very unsatisfactory, we had almost said a discreditable, position of affairs, but there seems to be nothing left for us but to put up with it as best we may. It is, however, only reasonable to expect that, so far as most questions are concerned, executive bodies administering the law as it stands will not, pending the delay, make themselves more than necessarily offensive in the discharge of their immediate duties. The Commissioners in Lunacy sorely need a little pointed advice on this subject, and, whether they accept it or not, we will make bold to offer our counsel. Until it is finally decided whether local authorities are to be entrusted with the provision of asylum accommodation for the paying as well as the pauper lunatics of a county, the Commissioners in Lunacy might with very good grace forbear to put into execution perfectly new ideas with respect to the construction of asylum buildings. For example, nothing can be more absurd than for the Board at Whitehall—which we earnestly hope is on the eve of being reformed or superseded—to lay down and enforce a rule that a county asylum must needs be erected on a plateau of twenty-five acres of land, and have a frontage extending some 600 feet. Why, in the name of sanity, "twenty-five acres"? and why "600 feet"? The first of these conceptions is manifestly a pure phantasy, and the last mentioned is a project having in it all the elements of madness. We strongly recommend the magistrates of Middlesex to withdraw their scheme and take refuge from the vagaries of a demented board in a masterly policy of inaction. *Quis custodiet ipsos custodes?* will have a new application if the official guardians of the insane do not speedily place themselves under some of the restraints of decency and common-sense.

Dr. FRANCISCO VINALS has been unanimously elected by acclamation of the Faculty of Medicine of Madrid as [illegible]

Annotations.

"Ne quid nimis."

THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS.

AT a meeting of the Committee of the Association of Fellows of the Royal College of Surgeons of England, held on Monday last, the following resolution was passed unanimously: "It being understood that a committee of the Council of the Royal College of Surgeons is considering a proposal made by one of the members of the Council to the effect that fifty Members of the College shall be elected annually and without examination to the Fellowship, the committee of the Association of Fellows—though favourable to the institution of increased facilities for Members of the College to become Fellows by examination—hereby expresses its disapproval of any attempt to lower the acquired academical status of the Fellowship, and pledges itself to resist such to the uttermost." A copy of this resolution has been forwarded to the President and Council of the College.

"HER MAJESTY THE QUEEN."

PROBABLY there is no Sovereign in the world whose health and happiness are so frequently an expressed desire of the people as that of "Her Majesty the Queen," for whenever a few of the English-speaking race meet together, if any sentiment is to be proposed, the health of Her Majesty stands first, and is loyally responded to by any gathering from among the many millions of the Queen's subjects in all parts of the globe. Those of our readers who have read the Greville Memoirs, the life of the Prince Consort, the life of Lord Palmerston, and that of Bishop Wilberforce, will have gathered that the cares of State press very heavily at times on the Sovereign of these realms, as well as on those high in office. Those who can call to memory the touching description in the "Four Georges," of the dear old "Farmer King," when a gleam of reason returned to him, his thanksgiving, his hopes, and his resignation, will be able to gauge the extent to which the "cares of State" may undermine a monarch's health. It should not be overlooked that Her Majesty has now reached the age of sixty-seven, and at this period most people are admitted to be fully entitled to some repose from the jostle and strife of life. The Queen, not less than the poorest of her people, is subject to the laws of nature, and at her period of life may fairly claim the affectionate consideration of her subjects at this the most trying crisis of Her Majesty's reign. The statesman who has just relinquished office has no doubt given every consideration to Her Majesty nor can we doubt that his successor in office will be equally mindful of what is due to the Queen. It is, however, "not only the constitutional right, but a constitutional duty, of the Sovereign to discuss with him (the Premier) confidentially all the aspects of the proposed ministerial changes, and to submit to the aspirant Premier such considerations as may suggest themselves bearing upon the expediency or the possibility of a successful issue." This sentence (from *The Times* of Feb. 1st) will convey to our readers some idea of the weight of responsibility resting on Her Majesty. Medical men can estimate better than others the possible and probable effect of this anxiety. There is a limit to what human nature can bear, and the Queen is no exception to the rule. If, however, Her Majesty could for a time remove the Court to Windsor, if not to London, the convenience to public business and to her ministers would be very great during the present political crisis.

PORRO'S OPERATION; SURVIVAL OF MOTHER AND CHILD.

La Gazzetta degli Ospitali (Jan. 20th, 24th, and 27th) reports the case of C. C——, admitted June 10th, 1884, in the Gynæcological Clinique of Pavia under Professor Cuzzi. The patient had suffered much from infantile rickets, and only walked with difficulty at seven years of age. She menstruated at twelve, was married at twenty-six, and had a history of seven pregnancies. The first resulted in the birth of a living child at seven months, the second in abortion at three months, the third in a living child at full term, the fourth in twins born alive at seven months, the fifth and sixth in living children at full term. The patient remained in comparatively good health for five years, when she again became pregnant. Her health suffered greatly, she endured intense pain, and sought admission into the Pavia Clinique in the eighth month of gestation. She was greatly debilitated, and the pelvis so much deformed that the lower outlet barely admitted the exploratory finger. Labour pains commenced at 1 P.M., July 22nd. As natural delivery became obviously impossible, in the absence of Professor Cuzzi, who had foreseen the probable necessity of operative interference, this was undertaken, with competent assistants, by Dr. Guzzoni degli Ancarani. The patient having been placed under chloroform, and strict antiseptic precautions adopted, an incision eight inches long was made in the middle line, and, according to Müller's modification of Porro's operation, the uterus was bodily brought out through the wound and an elastic tube applied round the cervico-uterine cone (*sul cono cervico-uterino*). Having divided the uterus, broken the membranes, and extracted the fœtus, the operator replaced the elastic ligature with a wire one; he then amputated the uterus and applied perchloride of iron to the stump. Having quickly completed the peritoneal toilette, the stump was fixed with a strong needle passed below the metallic ligature, the wound sutured with antiseptic silk, styptic colloid applied to the edges, and the dressing completed. The operation lasted for a few minutes over the hour. The woman woke in good condition, and had some repose after a hypodermic injection of sulphuric ether. The child, a male, was living. All the sutures were removed the seventh and eighth day. Convalescence was uneventful; the patient left her bed the forty-fifth day, the clinique for home the eighty-second day after the operation, and continued in fairly good health when seen a year afterwards.

THE PERILS OF FOOTBALL.

THREE weeks ago we called attention to a sad fatality at football, the third that had then occurred this season. In the short interval from then till now three more deaths have been recorded in the papers. On Jan. 22nd, John Francis Ashmore died from the effects of an injury received whilst playing in a match at Eckington. It is stated that after playing between five and ten minutes he was charged by one of the opposing players, who, it is alleged, kicked him in the stomach. Nothing serious was expected, as Ashmore continued playing; but shortly afterwards he went home, and became much worse, with intense pain in the stomach, and death ensued within twenty hours after the injury. On Jan. 27th a youth named Nathan Pilling died at Widnes. A few weeks previously he is said to have taken part in a football match at Penketh, near Warrington, when he received a kick in the stomach, and was carried off the field in an insensible condition. He was afterwards for a time in fair health, but two days before his death he was seized with fits, which continued until he expired. Last Saturday, during a football match played at Keighley, a young man named Benjamin Walker picked up the ball from a "scrimmage" and attempted to get away with it. He was, however, "tackled" and fell, the opposing players in the rush falling upon him. Walker's head was doubled under his breast, and it being evident that he was seriously injured he was taken to Keighley Cottage Hospital, where it was found the spinal cord was ruptured. The unfortunate man lingered until Sunday evening, when he died. We regret not to have seen any account of the inquests held in these cases. Some more strong expressions of opinion on the part of juries might have a good effect. It is obvious that something will have to be done to modify the extremely dangerous way in which football is at present played. Six deaths, accidents innumerable, and who can tell how much suffering and deprivation to the victims' friends, emphasise strongly the need for radical measures of reform.

PTOMAINES AND LEUCOMAINES.

THE physiological action of ptomaines from putrefying meat has been studied by M. Gautier by extracting the alkaloids and examining them according to their solubility in ether, chloroform, and amylic alcohol. The alkaloids obtained by digesting with ether caused convulsive movements, rapid action of the heart, injection of the ears, stupefaction and contraction of the pupil in dogs. The chloroform extractives accelerated markedly the respiration, and slightly the action of the heart, and also injected the conchæ; the symptoms disappeared in fifty minutes in a dog of medium size. The amylic alcohol alkaloids paralysed the movements of frogs, dilated the pupil, and killed with general relaxation of the muscles. Free ptomaines are more dangerous than their salts, and especially those that are soluble in ether. Dilatation of the pupil, tetanic convulsions soon followed by muscular flaccidity, slowness of the heart's action, absolute loss of cutaneous sensibility, and loss of muscular contraction were the chief phenomena observed in frogs. Irregularity ending in contraction of the pupil, remarkable injection of the concha of the ears due to vasomotor paralysis, slow respiration, somnolence succeeded by convulsions and death, and loss of muscular contractility were the main effects witnessed in dogs. For a long time M. Gautier has averred that the alkaloids of putrefaction vary according to the nature of the soil in which they are developed. MM. Brouardel and Boutmy have considered that they varied also according to the time at which the bacterial fermentation began. Further, M. Gautier has noted that, whatever be the nature of the soil, the compound hydropyridic alkaloids, and especially hydrocollidine, are found in a constant manner, and appear to be the alkaline products of bacteria that have most vitality, and suffocate all the other kinds. Turning to leucomaines, M. Gautier in 1881 announced that the excretions of animals contained bodies of the nature of ptomaines. If the elimination of these leucomaines were diminished by any of their ordinary routes of exit, it is not improbable, in M. Gautier's view, that they might lead to disease. With the object of confirming his preliminary observations he has studied the muscular juice of large animals, and has extracted five new alkaloids, perfectly defined and crystallised, endowed with a more or less powerful action on the nervous centres, causing sleep, fatigue, even vomiting and purgation, after the fashion of the alkaloids of venom, but less actively than the cadaveric sorts. He appears also to have shown that these alkaloids are produced side by side with carbonic acid and urea in the ordinary metabolic activity of the tissues. It remains to consider by what mechanism these alkaloids are produced; whether they are engendered by physiological or pathological decomposition; what is the consequence of their incessant formation in the economy; what happens to them, and how we escape from their evil effects. Thanks to the respiration and to the

Digitized by Google

circulation of the blood, oxygen is able to penetrate everywhere in the animal organism; it does not follow, however, that the successive phenomena of assimilation and disintegration of tissues in animal life are essentially aerobic—in other words, oxidative. M. Gautier endeavours to prove, on the contrary, that many of the transformations in the tissues of higher animals are anaerobic. The mode in which we resist the action of the alkaloids formed in our tissues is twofold—elimination and destruction by oxygen. Elimination is effected by the kidneys, alimentary tract, and skin; oxidisation is probably chiefly effected in the circulating blood. Any cause that diminishes the access of air to the blood, or causes a decrease in the amount of hæmoglobin in the body (as in chlorosis and anæmia), or the introduction into the blood of substances that prevent the respiratory changes, leads to the accumulation of azotised substances of the nature of ptomaines and leucomaines.

ALLEGED DEATH FROM VACCINATION.

UNDER the title "Alleged Death from Vaccination" the *Earlestown Guardian* of Jan. 30th gives an account of an inquest which was held on Jan. 22nd, at Lowton, on a female infant aged three months, who had been vaccinated on the 19th inst., and who died on the morning of the 22nd inst. The mother took the child to bed on the previous night, and she slept quietly until 5 o'clock in the morning, when she screamed. The mother, believing the child required food, supplied its wants, when the deceased closed her eyes and died without a struggle. The child, who had been vaccinated on the right arm, was found to be greatly discoloured on the right side of the body and neck. The parents believed that vaccination had something to do with the death of the child, and hence an inquest was held, but they objected to a post-mortem examination, and in the absence of any evidence as to the cause of death an open verdict was returned by the coroner's jury. It is a matter for regret that all the circumstances attending the death of the child were not fully investigated. The newspaper report of the proceedings does not make it clear whether the discolouration referred to was due to post-mortem changes. If the child had suffered from septic poisoning, the result of vaccination, its condition would have been apparent to the mother before she took it to bed on the 21st inst. Its death may have been due to asphyxia caused by the feeding, or to convulsions, which had no relation to the vaccination. The exact cause will probably never be known.

THE CORPUS CALLOSUM.

THE current number of the *Liverpool Medico-Chirurgical Journal* contains a paper by Professor D. J. Hamilton, in which he clearly sets forth the discoveries he has made upon the structure of the corpus callosum, which were brought before the Royal Society and have important bearings upon the presumed function of this part of the brain. Professor Hamilton has shown, by means of most carefully prepared sections of the whole brain in the adult and of the fœtal human brain, as well as of the brains of animals possessing a corpus callosum, that the general belief in this structure being a commissure between homologous parts of the cortex of the two hemispheres is erroneous. He describes the corpus callosum as composed in its whole extent of decussating fibres, which arch upwards, outwards, and downwards into the centrum ovale. What one may perhaps term the incoming bundles of fibres (as regards the corpus callosum) of this crossed callosal tract can be traced from all parts of the cortex, passing down mostly along the margin of the great longitudinal fissure; whilst the out-going bundles, instead of forming, as ordinarily taught, a similar but opposite series, turn downwards into the inner and outer capsules. The proofs of this rest upon three groups of facts—viz., (1) that the "crossed callosal tract" corresponds in extent with the whole extent of the corpus callosum; (2) the arching of the fibres outwards and downwards, a fact long since noted by Foville, but disputed by Meynert; and (3) the actual tracing of bundles of fibres from the cortex of one hemisphere to the capsules of the opposite. The special methods of preparation employed by Professor Hamilton have aided him in making this demonstration, rendered the more difficult by the various directions in which the fibres seem to converge at the inner capsule, so that it is impossible to make sections in any plane which do not divide some of the fibres. In his paper in *Brain* (July, 1885) Professor Hamilton showed that in the fœtal brain the crossed collateral tract could be well demonstrated. As he does well to point out, these fibres have no direct relation with the motor tract, and it is absurd to suppose that he intended to demonstrate that there was a higher decussation of the motor fibres than that in the pyramids. The motor tract is perfectly distinct from the callosal, the office of which appears to be to connect the cortex with the basal ganglia; and it is only in accordance with what seems to be a general law of the nervous system that such connecting fibres should decussate. As yet pathology has contributed little to confirm Professor Hamilton's discovery—viz., in the occurrence of secondary degeneration of the callosal fibres; but he refers to a case recently in the Aberdeen Asylum of a woman sixty-two years of age, imbecile from birth, in whose brain there was absence of portions of the cortex on the right side, and of the capsules and island of Reil on the left, with concomitant absence of the left crossed callosal tract.

THE USELESSNESS OF INQUESTS WITHOUT POST-MORTEM EXAMINATIONS.

WE have frequently pointed out the inutility of inquests without post-mortem examinations, but never have had a better illustration of our remarks than an inquiry concerning the death of a boy held at the Foundry Inn, Wigan, on Wednesday, the 27th ult. The boy, aged thirteen years, was said to have received a kick from another boy on the 16th. He did not complain till Monday the 18th, and he went to school on the morning of that day. At noon he complained of pain below the knee and pain in his head, with vomiting. Medical aid was sought on Wednesday, the 20th, and on examining the leg no mark of violence could be seen. Warm applications were ordered, and the vomiting and head symptoms were treated. On the 21st there was slight swelling below the knee, some stiffness, a good deal of pain when the leg was moved, head symptoms more marked, conjunctiva suffused, slight delirium, temperature 101°, and restlessness. Linseed-meal poultices were now applied. The symptoms increased, the delirium became more marked, and on the evening of the 23rd the temperature was 104°, with redness and swelling below the knee and very slight fluctuation. On the 24th another practitioner was called in, who considered it to be a case of blood-poisoning from the kick. He incised the swelling and some pus escaped; the head symptoms, however, increased, and the boy died the same evening. A certificate of death from septicæmia was given but the registrar, being informed of the kick, communicated with the coroner, who decided to hold an inquest. This was done, as we have stated, on the 27th ult. No post-mortem was ordered and no medical evidence called. The jury, after hearing the evidence of the father and another witness, found the following verdict: "Died from blood-poisoning caused by a kick received whilst playing with another boy," and that no one was to blame. The medical men of Wigan have, we believe, as a rule no ground of complaint against their coroner, who generally consults them, orders post-

Digitized by Google

mortems frequently, and calls them to give evidence. Here therefore we have an exception to prove the rule, but it is in a case which surely demanded both a post-mortem and medical evidence, especially as another boy was supposed to have caused all the mischief, and if so should probably receive some share of blame. But we are of opinion that, had a post-mortem been made, evidence would have pointed to acute meningitis as the cause of death, with the suppuration as a coincidence. At all events, it is not usual to have acute septicæmia without broken skin or an open wound. Inquiries of this nature, therefore, are useless unless accompanied by both post-mortem examinations and medical evidence.

RUPTURE OF THE UTERUS.

AN inquiry was recently held at the Black Swan, Brighouse, Yorkshire, by Mr. Barstow, the district coroner, into the circumstances attending the death of Elizabeth Gath, aged thirty-eight. It appears from the evidence that the deceased woman was taken in labour on Jan. 12th, at 2.30 A.M., and that a midwife who had been engaged to attend her was then sent for. The latter person on her arrival found that parturition was in progress, the membranes having ruptured. Upon vaginal examination she found that there was an unusual presentation, but what she actually did to expedite labour and with what result was left in doubt. Within an hour, more or less, deceased was seized with "a sick fit," as narrated by the midwife, from which she never rallied. Recognising the gravity of the case, she sent for a medical man, but not until more than an hour had elapsed from the onset of the fatal symptoms. When he reached the house he found the patient dead. It was admitted by the midwife that she seized a leg of the fœtus and brought it down, using, according to the testimony of an eye-witness, very great force. There can be no reasonable doubt that the so-called fit was an attack of syncope caused by rupture of the uterus, and the questions at issue were whether such rupture occurred spontaneously or through the instrumentality of the midwife, and, in the latter event, whether there was culpable and criminal negligence. Dr. Bond, the doctor consulted, asserted that the midwife told him in the first instance that the attempt to assist delivery was made prior to deceased evincing symptoms of shock before referred to. At the inquest she stoutly denied the truth of this, and persisted in her statement that she made traction on the leg subsequently to the "fit." At the post-mortem examination made by Dr. Bond, a rent twelve inches long was found in the uterus on the left side towards the front, and in that portion of the uterine wall which had impinged on the pubic bones there were some extensive bruises extending through its whole thickness. It became a matter for consideration whether these bruises could have been produced by the uterus being driven against the pelvis by its own contraction, or whether it was not more likely that they were caused by forcibly pulling on the leg of the fœtus. To say the least, it is not usual to meet with extensive bruisings distant from the rupture, but we are far from denying that such may not occur independently of the application of extraneous force. The jury found a verdict that deceased died from syncope brought on by rupture of the uterus, but how the rupture was induced there was not sufficient evidence to show. They censured the midwife for not having called a medical man earlier, and the coroner observed that she had contradicted herself whilst giving her evidence, and administered a caution to her as to her conduct of midwifery cases in the future. We are of opinion that the demands of justice were fully complied with. It is highly probable that had the midwife been committed for manslaughter the grand jury would have ignored the bill of indictment. In the first place, the accident which happened is of such an appalling nature that, whether it occur spontaneously or be caused by artificial means, it is not to be wondered at that persons in charge of the case should be unnerved, seeing they are utterly helpless to avert the catastrophe. Whilst we admit that it is an excellent system for trained and competent midwives to attend the poor in their confinements, we contend, nevertheless, that whenever the slightest difficulty arises in the course of labour it is the bounden duty of the midwife to summon medical aid without a moment's delay. The recorded cases of spontaneous rupture of the uterus are so numerous, that the fact of rupture in a given case is not in itself at all convincing that it arose from other than natural causes. We cannot subscribe to the editorial article in a local paper, where it imputes blame to Dr. Bond. From our reading of the case, that gentleman acted in an exemplary manner, and gave his evidence with the greatest fairness.

THE RATING OF CHARITIES.

THE *Charity Record* is doing good work in directing the attention of members of Parliament to the measure that is being promoted by an association just formed "to obtain a Bill to secure for public charities the restoration of the exemption from local rates which they enjoyed prior to the year 1866." The replies to inquiries on this subject from twenty-six metropolitan members are very interesting. We are not the less gratified with them because they are not all blandly favourable to the proposal of exemption. But they show an intelligent appreciation of the questions involved, and a disposition to be considerate to the charities. When the voluntary charities of this country are duly estimated, as they can only be by comparison with the State-supported charities of other countries, Parliament will feel the force of the argument for exempting them. The charities of this country save the ratepayers and the taxpayers by doing that which in other lands is done by the State. Surely the least the State can do in return for such generous action of individuals on behalf of the poor and the pitiable is to exempt the buildings from rates. We know only too well the burdens of the ratepayers. But the charities immensely relieve the burdens, and should themselves be relieved of rates. According to a rigid political and fiscal doctrine perhaps they should be rated, but if this hard political doctrine is pushed it will give another blow to our voluntary system, which in these hard times it is very difficult to maintain.

PAUPERS AND PORRIDGE.

THE casual wards, or rather the cells, attached to the Westminster Union workhouse have been particularly crowded this winter. Comparing the first five weeks of this year with the corresponding period of last year, the following is the number of casuals who have obtained relief. During the first week of 1885 casuals of both sexes numbered 49, and during the first week of this year there were 78; the second week of 1885, 62, and 115 in 1886; the third week, 71 and 98 respectively; the fourth week, 84 and 102; the fifth week, 73 and 80. Such a notable increase seemed due to the prevailing commercial depression and the number of persons out of employment. The master of the workhouse, however, did not agree with this suggestion. He said that the increase followed immediately upon the improved dietary now given. Formerly only half a pound of bread was included with the night's lodging; now a pint of porridge is given, and this is a fairly substantial meal, for as much as a pound and a half of oatmeal is mixed with eight pints of water. On the other hand, this district has availed itself of the new and optional Casual Wards Act of 1882, by which the applicants are detained during two nights and a day.

Digitized by Google

formerly the labour test was completed at about eleven in the morning, and the casual then released. It was argued that this was not sufficiently severe, and also that eleven was too late in the day to obtain work. The unfortunate men and women are therefore kept overnight, and then released at seven or eight on the following morning. Thus we have a clear proof that a bowl of porridge is sufficient to determine a considerable increase in the number of persons seeking shelter in the casual ward, though this little advantage is counterbalanced by two nights' imprisonment and a day's oakum-picking. The cells are not so comfortable as those occupied by ordinary criminals, yet in one single district more than a hundred persons during the course of the fourth week in January voluntarily submitted to imprisonment and hard labour for the sake of a little oatmeal porridge. What a picture of suffering and starvation these few figures afford. No wonder that illnesses due to insufficient nourishment are of frequent occurrence. Nor is it surprising that a cry should be raised in favour of organising the unemployed, and securing for them, from the State if needs be, work of a more remunerative and useful character than mere oakum-picking. For our part, without intervening in this economical problem, we can at least insist that energetic measures must be adopted to provide food where it is absolutely wanted, otherwise the public health will be gravely compromised.

THE PARASITICIDE TREATMENT OF LUPUS.

PROFESSOR WHITE, of Harvard University, starting upon the basis that lupus is a form of tuberculosis of the skin, and that it consists of chronic inflammatory changes in the tissues produced by the presence of a bacillus, has sought to found a simple and rational treatment by bringing into contact with the bacteria some substance which, without injuring the animal tissues, will destroy the life of the bacteria. Stimulated by a paper by Doutrelpoint, he has used in twelve cases bichloride of mercury ointment and lotion in the strength of 1 to 2 grains to the ounce, and in some salicylic, 2 to 4 per cent. dissolved in castor oil. He found the lesions of lupus in their early forms rapidly acted on. The tubercles quickly shrivel and become paler, and the skin returns to its normal condition in a few months. In the ulcerating forms the action of the sublimate is slower and much more uncertain. He recommends the sublimate ointment as the more effective, to be used twice daily, but in the ulcerating forms he prefers the lotion. It is necessary to be on one's guard against salivation when the remedies are used about the mouth.

FOOD REFORM AND WORKING MEN.

THE meeting of working men interested in food reform, over which Dr. Richardson was invited to preside on the 27th of last month, was a remarkable indication of the deep and intelligent interest which working men of all classes are now taking in social and scientific progress. It is true that, as the audience was selected from the employés of over forty of the great firms of the metropolis, it may be considered as intellectually above the average of those whom it represented; but anyone looking into the City and Colonial Club during the sitting might easily have supposed that the conference was being carried out by members of the professional and so-called learned bodies, rather than by men who had been all day at some handicraft industry. The speakers understood the rules of debate; they spoke with excellent knowledge of their subject, and they elicited cheers as men knowing that even the legislators at Westminster could not touch any topic more important for the national life than that on which they themselves were then and there engaged. The matter under discussion was a cheap, well-cooked, and substantial dinner for working men and school children. The proposition, made by Mr. Tallerman, whose interesting lecture was well received, was to this effect: that near all great centres of work there should be a food depôt, where food, bought at first price, should be prepared in such a form that it could be cooked in a water-bath provided at the workshops. Each man would thus receive each day one pound of food, consisting of meat, flour, and vegetables, ready to be cooked, and would have nothing more to do than take his "digester" off the water-bath, open it, and find a dinner, varied every day in the week, which would satisfy his wants, and cost him altogether threepence at most. The plan seemed to take so well that a committee of representatives from sixteen societies or firms was elected to confer on the whole scheme, to meet the members of the Farmer's Association (if that were possible), and to report to another general meeting on Wednesday next. Should the report of this committee be favourable to the scheme, an experimental trial will be carried out for one month, the results of which, whether they prove a full success, a partial success, or even a failure, will lead to a certain good by opening the way to the solution of a weighty problem, second, as the Chairman said, to none other in the present national difficulties—namely how to make our food supplies so secure that under no pinch could famine, the mother of revolt, bring forth revolution.

THE SOUTH KENSINGTON EXHIBITIONS.

IT is stated that the Inventions Exhibition has resulted in a deficit. The loss is said not to be likely to exceed £5000, but the surplus of former successes has now disappeared. We are very sorry to hear this, since the disappearance of the surplus means, we fear, the annihilation also of our hopes that the hospitals, which are so sadly in want of funds, might materially benefit by the popularity of these gigantic "shows." The electric lighting last year was a complete success, and afforded as beautiful a sight as the eye could desire to look on; the Austrian band discoursed dance music most tunefully; but if it is true that the former cost nearly £40,000 and the latter £6000, our memory of them cannot but be tinged with regret and jealousy. One-half of this sum would seem a large one to spend on recreation; how well might the other half have been devoted to the relief of suffering!

MENINGEAL AND CEREBRAL MANIFESTATIONS IN MUMPS.

As a contribution to the study of nervous disorders consecutive to acute diseases, the article by MM. Lannois and Lemoine in the current number of the *Archives de Neurologie* deserves careful attention. The authors wish to demonstrate that the occurrence of aphasia and paralysis in the course of mumps is dependent on lesions of a grave nature of the brain itself. These serious lesions are not transitory, but last a certain length of time. Dr. Monro's case, published in THE LANCET, August, 1883, is quoted. It was that of a boy, aged fifteen, who contracted mumps, and after apparently recovering was attacked with delirium, fever, and, one day later, orchitis. The fever increased to 106° on the fifth day; the pupils were dilated and insensitive to light, and there was marked constipation. The delirium increased and necessitated restraint. On the eighth day coma set in and the pulse became almost imperceptible. Although the temperature abated slightly, still the patient had several maniacal attacks. At last he returned to complete health. But he had much difficulty in walking for six months, and also considerable trouble in speaking and writing. The pupils

Digitized by Google

remained dilated, and the patient was highly emotional. In another case aphasia and localised paralysis of the right arm lasted for more than five days. The authors detail a case in which the aphasia and right hemiplegia lasted many months. It is their province to inquire into the nature of such cerebral disorders in mumps. Whilst admitting that hyperæmia or embolism might account for some of the cases, the hypothesis of a meningo-encephalitis is suggested. Generally this inflammation leads to nothing more than a superficial irritation, that rapidly passes away after having given rise to symptoms far more formidable in appearance than in reality. At other times, though fortunately of infrequent occurrence, the congestive stage is followed by encephalitis, which accounts for the long duration of the symptoms. The local removal of blood in cases of cerebral symptoms supervening in mumps is regarded as sound treatment.

THE FINANCIAL ASPECT OF A MEDICAL LIFE.

SPEAKING generally, we may say that, in the case of medical men as of others, unsteadiness and incapacity have more to do with the production of poverty than any other cause. On the other hand, wealth is not usually to be acquired in the practice of medicine. What we may call small fortunes are not uncommon; but, as a rule, the rewards of practice are such as most men sketch into their future when they enter on a medical life—namely, a large amount of useful work not wholly remunerative, means sufficient to maintain comfort and refinement at home, and retirement in easy though not affluent circumstances. These conditions, though they do not assuredly come about without effort, ought to be attained within a term considerably short of that allowed to the life of man. Some method will doubtless be necessary to accomplish this end; but in no calling probably is its final accomplishment more to be relied upon. With this view economy must, of course, find a place among the principles of the practitioner. In some directions the practice of this virtue at the present day might, perhaps, be improved upon, though the omission where it exists is by no means an error of choice with most of our medical brethren. There are, for example, the working expenses—among them the dispensing system. Many practitioners maintain that this custom pays them. In some respects perhaps it does; but undoubtedly there are those on whom it levies a very heavy tax indeed, particularly where it adds a fruitless bounty to a bad debt. Then there is the professional carriage. This is often regarded as one of the standing requisites of practice. Here, again, a rule would seem to have been formed where the fixity of law is undesirable. We are aware that all doctors do not drive. Some very busy men do not. Nevertheless the old order on the whole prevails, and forms a needless bugbear and incubus on many a young practitioner. Medical men would do well to consider how far such working expenses are indispensable. In many cases the public would not be prejudiced by their abolition. If we pass to other spheres of economy, something may still be learnt. The practitioner, once established, who would reap from professional work its monetary due, should not be slow to begin saving. If he cannot for a time lay by much, he can at least in most cases insure his life, and we presume usually does thus much. But further, if disposed, he may, better than many, provide for some return within his own lifetime. The uncertainty of his engagements does not permit profuseness in hospitality. His life is in this respect a somewhat quiet one. It lacks something of social display, of which there is already more than enough elsewhere, but it does not therefore deny him the best culture of which human nature is capable. He may fairly avail himself of this arrangement, which he did not contrive, and live and entertain modestly. Extravagance does not seek him as it seeks some men—it has to be sought for, and his blame is the greater if it swallows up his revenue. Some medical men are very fond of watching the share market. They follow its fluctuations, buy in and sell out. If their judgment is good they may prosper, as some conspicuously have done. Others have lost as heavily. The capacity of men in this direction must necessarily depend very much on the time they can devote to their ventures. Obviously, therefore, those who are most employed in practice run some risk in the market. Their safest plan would be to act like keepers of a trust, to invest in a well-known and approved stock, and there let their money lie. These few hints appear to us to indicate in some sort the plan of financial development which belongs to the life of the practitioner of medicine.

SHOW-CHILDREN IN THE STREETS.

WE have long been accustomed to hear that mortality amongst young children is in great measure the result of parental neglect or mismanagement. The saying appears almost too trite for repetition, were it not that examples of its truth so frequently force themselves upon our notice and call for practical and exemplary correction. The present season contributes its share of this kind of cruelty. Many will have observed with regret that the practice of exposing infants for begging purposes continues to disgrace our streets. Infants and children generally are notoriously less capable of resisting cold and wet than adults. A bronchial cough is one of their most fatal troubles, yet here we find these begging children scantily clad, and out at all hours, and in any kind of weather, in order to excite the charity of passers by in favour of those who lead them about and live upon their misery. How often the child's companion is a parent, or how often both are equally homeless, no one can say. Almost any shelter were better than the street. In very many cases there is reason to believe that the shivering singing child or carried baby is a castaway, nobody's offspring, and anyone's means of livelihood for the day, till its own days are numbered. It is somewhat difficult to see how any one plan would meet every form of this abuse of infant life. The exercise of individual charity would only augment the evil. The wholesale consignment of such children to homes or workhouses might not be much happier in its results. Probably the best plan, however, would be to allow the police considerable discretionary power to take in charge and transfer to the workhouse or to charitable institutions infants who are thus exposed.

HEREDITARY GENIUS.

MR. GALTON, in an address lately delivered to the Anthropological Society, gives the results of his inquiries into hereditary stature and hereditary genius. He proposes a scheme for the formation of an Upper House of Legislature in Utopia on purely scientific principles; and, in the evolution of this scheme, remarks that men who earn distinction of a high but subordinate rank to that of the nobility, and whose wives have hereditary qualifications, should transmit those qualifications to their children. He calculates—roughly and very doubtfully, because many things would have to be considered—that there would be about twelve times as many persons hereditarily qualified to be candidates for election as there would be seats to fill. A considerable proportion of these would be nephews, whom he would be sorry to omit, as they are twice as near in kinship as grandsons. Setting aside the question of the closeness of relationship, which seems open to discussion, it is natural to ask, What would happen if the father of the nephew happened to marry a woman without hereditary qualifica-

Digitized by Google

tions? would not the strain be detected? or might it not, if the selection were injudicious, be actually deteriorated? We have not the text of Mr. Galton's address before us, but imagine that what he desired to impress on his hearers was that those who possess unusual abilities in any direction would do well to select for helpmates those who are healthy and strong, and possess an average if not an unusual degree of intelligence. With careful breeding, high mental qualifications may descend with such physical qualifications as long limbs, powerful muscles, or large and active brains.

A RUSSIAN PRACTITIONER PUNISHED FOR REFUSAL TO ATTEND.

WHEN a doctor in this country ventures to excuse himself from attending to some case, perhaps at a long distance, he runs the chance of a so-called censure by a coroner's jury, which he, knowing that in reality he has committed no fault, generally manages to bear without much loss of dignity. In Russia, however, a medical man renders himself liable to a much more serious punishment than a mere barren vote of censure. A short time since, a practitioner in Kieff, long past the prime of life and by no means in good health, received a visit from a lady requesting his immediate attendance at a confinement some five or six miles off. The lady stated that the patient was a multipara, and that a doctor who was with her had twice attempted to apply the forceps, but had been unsuccessful, and wished another doctor to be fetched to perforate the head. Two assistants in the obstetric clinic had been applied to, and they had stated that the instruments were locked up and the professor had the key! Two other practitioners had also excused themselves, giving as a reason their want of the necessary instruments. The elderly practitioner did not refuse to go, but mentioned that his fee would be 25 roubles (£2 10*s.*). To this the lady made no objection, but merely remarked that she would make inquiries. She did not, however, return, having found another practitioner, who visited the patient and perforated. Shortly afterwards an article appeared in a local newspaper giving a distorted version of the facts. The consequence was that the elderly practitioner was prosecuted in a court of justice and sentenced to eight days' arrest in his house and a fine of 5 roubles (10*s.*). Against this he appealed, his counsel urging on his behalf that the circumstances were not such as the law contemplates when it compels a doctor to attend to dangerous cases; that he, not receiving any written communication from the doctor who advised perforation, did not clearly understand the condition of things; that plenty of other medical men were available; that he did not refuse to attend; and, finally, that the law did not insist on a practitioner going to a case where another qualified man was already in charge. Notwithstanding all this, the higher court increased the sentence to fourteen days' arrest at the guardhouse, 5 roubles (10*s.*) fine, and the expenses of the trial.

QUACKS AND THE PUBLIC.

A CONTEMPORARY, discussing the leading characteristic of quacks of all classes in their relation to the public, justly points out that it is the pertinacity of their profession of ability to cure. "The quack has his pills and ointments, warranted (if taken in sufficient quantity) to restore health and vigour to the dying; and the ignorant and cowardly pin their faith on him, spurning the counsels that might assuage their sufferings, and consume the noxious drugs that precipitate their fate." This is a *fact* of which the orthodox and educated practitioner of medicine has daily evidence, of the most conclusive strength, and often driven home with painful force. We quite admit that there is sometimes too great a readiness to accept the hypothesis of incurability; but, speaking generally, the public are losers by the persistence with which they pursue the phantom of recovery, running from doctor to doctor, only to undergo new experiments and court fresh disappointments, rather than take prompt and full advantage of the practised skill of the experienced family counsellor in devising a method of minimising the injurious effect of their maladies, and finding a *modus vivendi* with disease. There is a spirit of quackery abroad in the profession of physic, as well as one that prevails outside and hovers on its borders. We do not know which is the most obstructive to true progress and most baneful in its influence on the health of the population—the quackery that professes to cure by irregular means, or the quackery that affects to be able to accomplish by accepted methods that which it is perfectly well known they are inadequate to achieve.

INTRA-CRANIAL TUMOURS AT THE PATHOLOGICAL SOCIETY.

A WONDERFUL array of cerebral tumours was exhibited before the crowded meeting of the Pathological Society. The specimens illustrated the tendency of cortical gliomata to remain limited to the grey matter, the opposite infiltrating characters of these tumours in the white substance, the rarity with which it is possible to localise with certainty the site of tumours, the difficulty of determining their size, and the extent to which they infiltrate their surroundings; the vast variety of clinical phenomena, and the variations in their anatomical and histological structure. The most conspicuous expression of opinion on the advisability or possibility of operating with a view to the removal of tumours was that essayed by Dr. Goodhart, who considered that the number of tumours which could with any degree of probability of success be regarded as suitable for surgical interference was very limited. It is needless to say that nothing of a novel nature was forthcoming, but the *tout ensemble* of the collection was effective and successful. The exhibition is to be continued at the next meeting of the Society.

THE ITALIAN HOSPITAL AT CONSTANTINOPLE.

SINCE Italy became a united kingdom she has revived that interest in the East which, during the supremacy of the Venetian Republic so profoundly affected her policy. In 1876 at Constantinople she established a hospital in the Tophané quarter, with an outlook on the sea, covering an area of some 3800 metres, and costing her about 300,000 fr. The edifice has two floors over the ground floor and eight windows in the façade. A hospital-villa would be its proper description, with its elegant aspect, its green shutters, and its verdant garden to the front. Two physicians are attached to it—Dr. Salvator, with 6000 fr., and his assistant, with 2000 fr., salary. Fourteen Sisters of Charity, with four male helps, are in attendance on the patients, and their chapel is quite a triumph of bijou architecture. Contagious maladies have six rooms reserved for them. On the first floor a large hall contains ten beds for females and three private rooms; on the second floor another hall has twenty beds for males and five private rooms; and there is also a ward with twelve beds for syphilitic cases. The two higher floors are reached by a lift, and provided with dressing-rooms and waterclosets, all in excellent order. Much care has been bestowed—successfully bestowed—on the ventilation, and a constant current of pure water, both fresh and salt, circulates through the building. Italian patients are charged six francs a day for private rooms, while foreigners pay eight francs, and in the common wards three francs and four francs. In 1884 the hospital received 309 male and 41 female patients, with

Digitized by Google

14·610 days for the former and 5·376 for the latter. There were 28 deaths. The paying patients in 1884 yielded 9600 francs, or about a third of the expenditure, not including the medical treatment. The rest is covered by the Ministry of Foreign Affairs. Adjacent to the hospital are a building for the insane capable of holding twenty patients, and the consular prison.

MEDICAL SCHOOLS AND STUDENTS IN THE UNITED STATES.

THE Illinois State Board of Health has recently issued a pamphlet entitled "Medical Education and Medical Colleges in the United States and Canada, 1765-1885," in which the most suggestive facts revealed by tables and data are: First, that the number of medical colleges has not increased during the past year; secondly, that the number of medical students and of medical graduates is decreasing; and thirdly, that there is a more marked uniformity in the requirements of colleges. There are still 128 institutions for medical instruction in the United States and Canada, the same aggregate as at the date of the last report. But there were 760 less students in attendance upon, and 273 less graduates from, the sessions of 1884-85, than upon and from the sessions of 1883-84. In the United States there were 953 fewer students and 278 fewer graduates; in Canada there were 176 more students and 5 more graduates. The schools are classified as follows: regular schools, 101; homœopathic 13; eclectic, 11; physio-medical, 1; and miscellaneous or mixed schools, 2. The number of medical students in 1882-83 was 13,088; in 1883-84, 12,762; in 1884-85, 12,002. In 1881-82 the number of medical graduates was 4555; in 1882-83, 4215; in 1883-84, 4101; and in 1884-85 only 3831. The increase in past years in students is most conspicuous in the smaller provincial schools; while in the large cities—Boston, New York, Philadelphia, Baltimore, Cincinnati, Chicago, New Orleans, and St. Louis—there has generally been a decrease. Thus the number of matriculants in medical schools in New York has fallen from 2209 in 1880-81 to 1826 in 1884-85. This fact may be interpreted in two ways. It may either mean that the metropolitan schools are getting more rigid in their requirements, or that the provincial schools are getting to be better educational institutions. We incline to the latter belief. The decrease in the number of graduates, noted above, is most satisfactory, indicating as it does a recognition on the part of the rising generation of the fact that in the United States, of all professions the medical is and for years has been the most overcrowded.

OCULAR TRAUMATISM AND FATAL MENINGITIS.

A PAPER read by Mr. Nettleship at the Ophthalmological Society deserves attention, not only from the gravity of the disease with which it dealt, but also from the obscurity of the pathology and the interest to general medicine of fatal meningitis following upon ocular mischief. The combination of traumatic diseases of the eye with meningitis is said to be of rare occurrence, and for this statement we have the evidence of all practical ophthalmic surgeons. The rarity with which the association is met, an association having also a time relation—for the eye injury precedes the meningitis,—naturally makes the logical mind suggest whether there is any causal relationship between the two phenomena, or whether we have to do with a mere coincidence. But tetanus is a rare complication of wounds; yet it is generally agreed that some close connexion exists between the nerve disturbance and the injury. Strictly logical methods would not allow us to deny altogether the impossibility of the idiopathic development either of meningitis or tetanus, even in cases where a traumatism exists. It would be easy to infer that the meningitis or the tetanus was related to the wound, even though it be impossible to state in what circumstances the wound with a sequel differed from the wound that healed without subsequent mischief. Guided by the light of modern researches on infectivity, we should probably adopt the view that the presence of some rare infective agent made all the difference.

PROPOSED ASSOCIATION OF THOSE QUALIFIED IN SANITARY SCIENCE.

MR. FOTHERBY writes, from St. George's Infirmary, Fulham-road, proposing the formation of an association of medical men who are specially qualified in sanitary science. The objects of the association would be: (*a*) To further the legitimate interests of all medical men who at the cost of much labour and expense have obtained a sanitary qualification; (*b*) to obtain a better general recognition of these degrees and certificates; and (*c*) to be a bond of social and professional union between all duly qualified practitioners of State medicine. We fully recognise the need for better recognition of the value of the special knowledge which is implied by these certificates, and the force of the arguments of our correspondent; but we doubt if great advantage would arise from the formation of another society. There are already several throughout the country devoted to furthering the interests of public health and of those who practise this branch of the profession, notably the Society of Medical Officers of Health; and we would suggest for the consideration of our correspondent whether he would not be better able to attain his object by utilising the already existing organisations than by the creation of a new one.

EPILEPSY AND OPTIC NEURITIS.

AT first sight the title of M. Galezowski's communication to the Académie de Médecine led us to expect a revelation somewhat similar to that experienced when Dr. Gowers asserted that chorea and anæmia may be efficient causes of optic neuritis. The matter, though interesting, is not so remarkable as that. Galezowski has recorded a remarkable case of epilepsy that supervened six years after a wound of an eye, and may with considerable show of reason be ascribed to morbid changes resulting in the stump of the eye. The useless eye had been reduced to the condition of a stump by amputation of the anterior hemisphere of the globe. Six years after the accident the sound eye became the seat of an optic neuritis, and at the same time the patient developed the typical seizures of epilepsy. Removal of the ocular stump was followed by perfect restoration to health, the epilepsy ceasing and the other eye recovering. Galezowski believes that sympathetic ophthalmitis is the result of the spread of disease along the vascular walls, probably by means of the vaso-motor nerves, thrombosis and sympathetic endarteritis being the consequence.

AN AMENDE HONORABLE.

AT the meeting of the St. Pancras vestry on Wednesday, at which the report of Mr. Shirley Murphy, the late medical officer of health for the parish, was presented and discussed, a graceful acknowledgment of the services of that gentleman during his tenure of office was made. Mr. Nathan Robinson proposed, and Mr. Churchwarden Dixon seconded, that the report be received and adopted, and that the best thanks of the vestry be engrossed on vellum, sealed with the official seal, and presented to Mr. Murphy. The significance of this act on the part of the vestry was enhanced by the remarks with which the proposal was accompanied, conveying as they did an admission of error, if not of something worse, in the dealings of the parish authorities with their late medical officer.

MEDICAL RISKS FROM INFECTIOUS DISEASES.

ONE of the most interesting features in Dr. Ogle's paper on Mortality in the Medical Profession, recently read before the Royal Medical and Chirurgical Society, is the comparison between the mortality of medical men from the principal infectious diseases, with the average mortality from the same causes among all males. That the mortality in the medical profession from these diseases should show a marked excess can cause no surprise to those who consider the constant risk of infection to which it is exposed. Dr. Ogle's figures are, however, mainly interesting from the exceptional position held by small-pox among these diseases. The death-rate of medical men aged over twenty years from scarlet fever is nearly four times the average rate of all males of the same ages; the medical rate from typhus is more than twice, from diphtheria nearly four times, and from malarial fever nearly five times the average rates for males of similar ages. Medical men are also liable to a markedly excessive rate from enteric fever and from erysipelas. The death-rate of medical men from small-pox, however, is considerably less than a fifth of the rate among all males. Dr. Ogle suggests the only possible explanation of this remarkable contrast between the relative incidence of these infectious diseases on medical practitioners when he attributes their low death-rate from small-pox to more general and better vaccination and revaccination; and their excessive death-rate from the other diseases to the fact that no prophylactic is known wherewith to counteract, as in the case of small-pox, their exceptional risks of infection. Dr. Glover, in the discussion which followed the reading of Dr. Ogle's paper, expressed disappointment that the profession did not show complete immunity from fatal small-pox, and it is well therefore to point out that the rate of 13 deaths of medical men from small-pox per 1,000,000 living implies that during the ten years 1873-82 only 2 deaths from this cause, out of 3865 deaths from all causes, occurred in the profession in England and Wales, numbering about 15,000. There were in England and Wales during those ten years 19,377 deaths from small-pox, and it is fair to assume that one or more medical practitioners were brought into personal contact with each of these deceased persons. Bearing these facts in mind, the deaths of but 2 medical men from this disease during these ten years induces overpowering evidence both of the value of vaccination as a protection from small-pox, and of its general and effectual adoption by the profession.

MOSQUITOES IN MEXICO.

THE city and environs of Mexico suffered so severely during the early part of last year from an invasion of mosquitoes in unwonted numbers that the Pedro Escobedo Medical Society appointed a committee to investigate the matter, and advise as to the measures which should be taken for the purpose of freeing the country as far as possible of these insect pests. The report of this committee is printed *in extenso* in the organ of the Society, entitled *El Observador Médico*. This report does not reveal any new points in the life history of the mosquito, but it recommends that, Mexico being surrounded by marshes and lakes full of putrefying matter which form admirable breeding-grounds for successive generations of mosquitoes, measures should be taken for draining the inundated localities in the valley of Mexico, observing that the most suitable time for carrying out work of this kind is undoubtedly the winter season, and requesting the Medical Society, if it approve, to lay the report before the municipal authority recommending immediate action. It is to be hoped that the *Ayuntamiento* will pay more attention to this memorial than is generally given by the local civic authorities in Central and South American States to hygienic measures, however warmly advocated by their medical faculties. If Mexico and other cities like it were really well drained, the inhabitants would probably find a diminution of many evils worse than mosquito bites, though even these, the committee were informed, had caused the deaths of children.

THE INCUBATION PERIOD OF VARIOLA.

PROFESSOR H. EICHORST, of Zurich, reports three cases in which the duration of the incubation of small-pox seems very clearly ascertained; and in each instance the time proved to be rather more than nine days. The first was the case of Dr. Kuhn, who travelled to Zurich to visit his father, who was suffering from the disease. Dr. Kuhn had not been in contact with small-pox until his interview with his father at 9 A.M. on Oct. 20th. The interview lasted three minutes, but there was no contact with the patient; yet in spite of this and as thorough a disinfection as possible, the son fell ill of small-pox on Oct. 29th, or nine days after exposure. The two other cases were those of medical students attending the small-pox hospital on one occasion only; they had both been revaccinated without effect, one within three weeks of exposure to contagion, which was accurately noted. In each case the symptoms of the disease appeared in a few hours over nine days from the date of exposure. Professor Eichorst says that he has treated more than 300 cases of small-pox in the last two years; but in no other cases than the above has he been enabled to determine with certainty the period of incubation; commonly this is assigned to twelve or fourteen days; but although variations may exist, no observations are trustworthy that admit of any possible fallacy.

MEDICAL EDUCATION IN RUSSIA.

IN England the cost of medical education is usually borne by the students' parents. In Russia, however, medical students are to a very large extent supported and educated by the Government, under not a mere understanding, but a well-defined pledge, to serve in any capacity that may be fixed for a certain number of years after qualification. This pledge is not uncommonly felt to be a burden, and a number of medical men at present under the obligation of serving the State have petitioned to be absolved from it. The *Pravitelstvenui Vestnik*, or "Government Messenger," has just published a ministerial hint to these gentlemen that only the cases of those who have appended to their petitions receipts for the return of the Imperial money expended on their education can possibly be considered.

THE SANITARY STATE OF CAIRO.

THE Egyptian newspapers are complaining loudly of the sanitary state of Cairo with regard both to its water-supply and the means of drainage. Briefly stated, the former is polluted, and as to the latter, there is nothing which deserves the name of a system of sewerage and drainage. The water-supply is derived from a stagnant canal, which at times emits abominable odours from human filth; it is filtered through sand excavated from an old cemetery, and there is strong reason to believe that further impurities reach it on its way to the consumers. Great difficulty is anticipated in securing an improvement in this supply, and this because, as alleged, the President of the Council of the Ministry is president of the water company, and derives a revenue from it. The drainage question has long been under discussion, but it is very much to be feared that, unless considerable pressure is brought to bear upon the authorities, the solution of the problem will be deferred to the Greek Kalends. In the

Digitized by Google

meantime the mortality of Cairo has reached a point which has very naturally caused alarm. It is just about three or four times as great as that of London, being at the rate of 60 to 80 per 1000. And not only so, but it is largely due to causes which result from the use of foul water or from the breathing of foul air. Typhoid fever is very prevalent, and so also are a number of other forms of fever which are less distinctly defined; and this prevalence is in striking contrast to the comparative absence of such diseases at Boolak, where the inhabitants derive their water direct from the Nile. Diphtheria, too, is very fatal; also a hybrid disease resembling cholera has been prevalent all the summer, and still continues. The general influence of these conditions upon the population of Cairo may be judged by the fact that for the last quarter of a century the deaths have exceeded the births by 37,000. And yet the climate is fine, the inhabitants are sober, and the waters of the Nile should conduce to healthiness. Dr. Grant Bey has taken an active part in pointing out the existing shortcomings; and it is to be hoped that his protests will receive the attention they demand.

STRAY MISSILES.

THE perils of the streets are considerably increased if to the ordinary ones is added that of stray missiles, carelessly or wantonly discharged. On January 26th excision of the right eye was performed at St. Thomas's Hospital for wound of the globe received two days previously. The patient, a man aged twenty-three, was walking, about 8.30 P.M., in the Lower Richmond-road, Putney, when he felt something strike him in the eye, the sight of which was immediately lost. He did not see anyone nor hear any unusual noise, and thought that he had been struck by a stone. On examination of the eye after removal, it was found to contain one of those leaden pellets or shots usually discharged from an air saloon pistol. It is probable that it will not be known who discharged the pellet, but we would try to impress upon the public the necessity of greater care in the use of these silent but dangerous toys. Had the pistol been discharged at a shorter range, the man would probably have lost his life. As it is, he is rendered ineligible for service in any of Her Majesty's forces, and has had to submit to a serious mutilation.

THE METROPOLITAN ASYLUMS BOARD.

THE Metropolitan Asylums Board at their last meeting, which was held on the 30th ult., resolved to take steps for the closing of the North-Western Hospital and for the reduction of the staff; and Sir Edmund Hay Currie, who presented a report from the General Purposes Committee, which contained a recommendation that this course should be adopted, commented on the fact that, with the exception of the autumn of the year 1879, London had not been so free from infectious disease for the last fifty years. During the fortnight preceding only six cases of small-pox had occurred in the metropolis, and these had been taken to the ships at Long Reach, where there were only twenty-eight patients under treatment.

"CURE FOR BLINDNESS."

A PARAGRAPH has appeared in several of the papers that a Dr. Emile Martin has invented an apparatus which will enable the blind to see. The mechanism, so the statement runs, is of platinum, and can be affixed without pain, so as to excite in the optic nerve the sensation of light and the power of vision. So high is the opinion the Paris Academy of Medicine has formed, *primâ facie*, of Dr. Martin's invention, that a committee of its members is reported to be now engaged in practically testing its merits. It is to be feared that the testing will end in disappointment. The word "blind" is very comprehensive. Will Dr. Martin's invention render the cornea transparent when opaque, and thus cure half the blind at a stroke? or will it restore the functions of the atrophic nerve with cupped disc too often seen in chronic glaucoma? or is it only a modification of the ordinary treatment by electricity?

SMALL-POX IN ONTARIO.

CONSIDERABLE efforts have been made by the Board of Health of Ontario to control the spread of small-pox which was recently prevalent in that province. Special regulations have been issued as to dealing with persons discovered to be infected with the disease, the systematic inspection of passengers, the performance of vaccination, and the conveyance of articles suspected of being infected. A codification of the laws relating to compulsory vaccination has also been prepared and addressed to local boards of health, medical officers of health, and members of the medical profession of Ontario.

THE HYPODERMIC SYRINGE AS A MILK-TESTER.

AN ordinary hypodermic syringe may be used, according to Dr. Hélot, for estimating the quality of human milk. He finds that the number of drops from the syringe of good milk are thirty-five or thirty-six to make up the same volume that can be dropped in thirty drops of distilled water. Similarly, when the milk is very poor the same volume can be dropped in thirty-three drops, and when extremely rich as many as thirty-eight drops are required.

FOREIGN MEDICAL APPOINTMENTS.

COUNT MAGAVLI, Doctor of Medicine and oculist to the Imperial Court, has been appointed a member of the Medical Council of the Russian Empire. Dr. A. J. Danielevski, formerly of Kazan, has been appointed Professor of Physiological Chemistry in the University of Kharkoff.

THE editors of the *Liverpool Medico-Chirurgical Journal* have introduced a new and useful department into their columns, in the form of half-yearly reports upon advances in medicine and surgery, the new remedies and methods of treatment noticed being first investigated and approved by a committee consisting of Dr. W. Alexander, Dr. James Barr, Dr. J. E. Burton, Dr. W. Carter, and Mr. R. Harrison. The current number of the journal contains two such reports—one on Antipyretics, drawn up by Dr. Barr, and the other on Antiseptics, by Dr. Alexander.

SEVERAL cases of scarlet fever have occurred in Canterbury, and it is alleged that the disease originated through the drinking of infected milk. In consequence of these reports, the dairies sub-committee of the Town Council have made a raid upon the dairies and milk-shops in the city, some of which have been found to be in a highly insanitary condition.

MR. WHEELHOUSE, of Leeds, has issued as a small tract, bearing the title "The Special Temptations of Early Life," the substance of the statement he brought before the Ripon Diocesan Conference last October. The pamphlet ought to be bought and read by heads of families and of educational establishments far and wide.

THE Special Board for Medicine at Cambridge University have issued a report recommending that papers on elementary physics should be introduced into the previous examination, instead of, or in addition to, the present examination in elementary mechanics.

Digitized by Google

THE new story by "Pen Oliver" (Sir Henry Thompson) will bear the title of "All But: a Chronicle of Luxenford Life." It will contain twenty-one miniature illustrations by the author, and will be published almost immediately by Messrs. Kegan Paul and Co.

THE medical officer of health of Stourbridge has reported to his Sanitary Authority the existence of a very severe epidemic of measles, necessitating the closing for a time of the elementary and Sunday schools.

PROFESSOR FILEHNE, of Erlangen, has been nominated Professor of Pharmacology at Breslau. The clinical chair at the University of Erlangen has been apportioned between Professors Strümpell and Penzoldt.

DR. HENRY MAUDSLEY is reported to be busy over a new volume of psychological research. It will bear the title "Natural Causes and Supernatural Seemings."

HEALTH OF THE NAVY.

THE Statistical Report on the Health of the Navy for the year 1884 shows the average force afloat, at home and abroad, to have been 43,000 officers and men. The cases of disease and injury among them were in the ratio of 1158, the deaths of 9·0, the number invalided of 49·34, and the mean daily sick of 51·61 per 1000. These ratios are all considerably higher than in the preceding year; the sick- and death-rates closely approximate the average of the last ten years, but there has been an increase in the proportion of invalids and of mean daily sick. The excess of sickness compared with 1883 has been chiefly from fevers and diseases of the digestive system, and in the deaths from fevers and injuries; the latter included 50 men drowned by the wreck of the *Wasp* on the Irish Coast. The following table shows the relative sickness and mortality of the different naval stations:—

RATIO PER 1000 OF AVERAGE STRENGTH.

	Cases.	Deaths from		Invalided.	Mean sick.
		Disease.	Injury.		
Home	902	4·30	3·93	40·54	51·85
Mediterranean	1431	5·75	1·24	81·49	52·39
North America and West Indies	992	2·48	1·23	22·31	35·06
S.E. Coast of America	1073	4·87	—	24·39	31·14
Pacific	997	4·0	0·66	26·0	39·95
West Africa and Cape	1117	5·72	1·42	36·42	38·92
East Indies	1741	15·03	8·29	75·12	53·11
China	1541	5·40	2·40	20·12	50·05
Australia	1003	3·31	3·30	23·14	44·70
Irregular	1422	10·51	3·62	77·75	66·19
	1158	5·84	3·16	49·34	51·61

Omitting the "irregular force," the East Indian station furnished the highest proportion of cases, deaths, invalids, and mean sick, upwards of one-fourth of these having been due to fevers, which were nearly twice as prevalent, and caused more than twice as many deaths and thrice as many invalids, as on the average of the last ten years. The *Euryalus* had 61 cases of remittent fever, occurring chiefly at Massowah, and of these 8 died; the *Briton* had 88 cases at Bombay, and their occurrence was believed to be connected with the insanitary condition of the *Auckland*, in which the crew were hulked while their ship was in dock. The *Auckland* has since been condemned as unfit for further use as a receiving hulk, and has been withdrawn from the service. The *Osprey* had 78 cases of remittent fever while cruising off Zanzibar and off the coast of Madagascar, and the *Tourmaline* had 47 while employed in the same service. There were only 4 cases of enteric fever reported on this station, all in different ships, but 3 of them terminated fatally. No cases of cholera occurred during the year. Thirteen out of the 45 deaths in this portion of the force were from wounds received in action among the men of the Naval Brigade employed in the Soudan, 3 at El Teb and 10 at Tamai; 9 of the latter were by spear and sword wounds, the others by gunshot. There were also 3 deaths from fractured skull by falls—2 from aloft, 1 into the hold. Next to the East Indies the China station had the highest proportion of cases, which, however, differed very little from the average of the last ten years, while the deaths were about 2 per 1000 under it. Diseases of the cellular tissue and cutaneous system, chiefly phlegmon, abscess, and ulcer, furnished one-fifth of the cases. Fever of the continued type was prevalent at Amoy and at Tamsui in Formosa. Ten cases of enteric fever were returned, 4 of them at Nagasaki and 2 at Hankow; the former were attributed to Japanese-made lemonade, partaken of while on leave on shore. Five cases of cholera occurred, 4 at Amoy and 1 at Shanghai, and 4 of them died; they are believed, like the enteric fever cases, to have been the result of drinking lemonade. "The exceedingly dangerous character of the aerated waters made in China and Japan ought to be constantly kept in view on the station, and their consumption prevented as much as possible."

The Mediterranean fleet had a higher ratio of cases than usual, chiefly due to fevers, but the deaths, exclusive of injuries, very closely approximated the average. The prevalence of fevers was attributed to the insanitary state of the harbour at Malta, to the turning up of the soil in the formation of a new dock, and the extensive drainage-works for the town of Valetta.

On the African station fevers were much above the average, but without any fatal case. The increase was due in a great measure to the occurrence of remittent fever on board the *Alecto*, at Akassa and Anamba creeks on the Niger, two very malarious localities.

The returns for the home station show a marked increase in the prevalence of syphilis and gonorrhœa; in most of the other classes of disease, there has been a decrease. The deaths were above the average, owing to the loss of 50 men in the *Wasp*. Excluding deaths from injuries, the ratio amounts only to 4·30 per 1000 of the strength. The returns afford important evidence of the value of isolation in infectious diseases: 34 cases of measles are returned, of which 23 occurred in the training-ships, generally in boys returning from leave, or contracted in the ports where the ships are stationed. "There was nothing in the form of an epidemic, the cases having been at once isolated, and effectual precautions taken against infection." In like manner with scarlet fever, of which 20 cases occurred, "each case appears to have been contracted singly during absence from the ship, and no secondary infection on board took place." There were 29 cases, and 8 deaths of enteric fever recorded; no case "could be ascribed to defective sanitation on board ship; nor was there any spread of the disease on board from secondary infection.....In almost every instance early removal from the ship for treatment in a hospital or sick quarters was resorted to."

The irregular force had very high ratios of sickness and mortality, considerably above the average of preceding years if the deaths from injuries are omitted. The excess of the cases was chiefly due to the prevalence of fever and of dysentery and diarrhœa among the men of the Naval Brigade

Digitized by Google

and the Royal Marine Battalion employed in the Soudan, and especially at Suakim. Five cases of enteric fever with two deaths occurred in the Naval Brigade among the men of the Nile expedition, and seventeen cases with nine deaths among the Royal Marines at Suakim. Remittent fever and diarrhœa were also very prevalent there. The deaths from fever amounted to 5·16 per 1000 of the strength, or upwards of one-third of the whole; and those by injuries to 3·61 per 1000, of which 1·20 were received in action. Of 21 deaths from injuries, 7 were caused by wounds received in action, 4 at El Teb and 3 at Tamai.

The strength of the Royal Marines at headquarters in England, not included in the general return, was 5060. The cases of sickness among them amounted to 1029 per 1000, the deaths to 3·35, the discharges by invaliding to 53·55, and the mean sick to 56·25. These are considerably lower than in 1883, but, except the deaths, they are all higher than in the force afloat employed on the home station.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Pollution of the River Ure.—Mr. Sweeting, who for some time past has been acting as a medical inspector to the Local Government Board, has submitted to that Board a very comprehensive report on the relation of the river Ure to the drainage and water-supply of Ripon and other places on its banks. The Ure rises on the northern borders of the North Riding of Yorkshire from the western slope of the great Shunnor Fell, by the influence of numerous streamlets which descend from the millstone grit of this mountainous region. It passes in its course through several sanitary districts, being joined by numerous streamlets of various size, and, passing through Ripon, flows on to Boroughbridge, just below which it is joined by the Swale and becomes the Ouse. The course of the river as it passes each inhabited place, and in so far as it relates to the different sanitary districts concerned, is given in much detail, and at each point where the river receives any sewage matter or other pollution, whether directly or indirectly, the local circumstances are fully entered into. From its source to its termination in the Ouse, it is directly polluted by twelve different places, the more important of the pollutions being at Masham, Ripon, and Boroughbridge. Other places pollute it more or less indirectly, and at one place the stream is made a receptacle for ashes. Ripon is the only populous town on the Ure which takes water directly from the river for drinking purposes, although local wells elsewhere—as, for example, at Boroughbridge—must almost of necessity be at times affected, as by the flooding of the river or its tributaries. Ripon lies below Masham, where a very substantial pollution of sewage is effected, and below three other places more or less implicated in the same way. As yet chemistry has not discovered any definite evidence that the water-supply of the city constitutes a real source of danger, but the relations of Ripon to the Ure must be regarded as serious in this respect. Ripon pours all its sewage into the river, and though the water-supply taken directly from the stream, more than one mile above the sewage outlet, does not appear at present to be suffering in any marked respect, yet the position of the intake is not free from objection; and there is always the danger of the entrance of specific particulate matter from places above Ripon. But this town is not the only place that is implicated in so far as the domestic water-supply is concerned. Richmond sends the sewage of nearly 8000 people into the Ure; Bedale sends its sewage in; and fifteen miles below Boroughbridge, where the river has becomes the Quse, York draws its supply from the latter river. It is not long since we had occasion to comment on an epidemic of enteric fever in York, reports on the prevalence having been prepared by Dr. Airy and Mr. Parkes; and though there appeared good grounds for [illegible] to other more obvious causes their the use of the Ouse water, yet the water-supply is not the less one that can only be regarded with suspicion. By the time the Ouse reaches York it has received not only all the impurities of the Ure, but, in addition, those of the Swale, and the sum total is unquestionably considerable. The contamination is largely due to fæcal matter, and hence numerous opportunities are afforded for the contamination of the water of the city by specific disease-elements. Whatever grounds of comfort the sanitary authorities of Ripon and York may find in the results of chemical analysis of their water-supplies, there remains the great fact that the sources of supply are largely contaminated by human excreta and other filth, and it behoves the sanitary authorities of both cities to consider earnestly how far they can regard such a water-service as a proper one for their inhabitants to consume. Mr. Sweeting's report, taking as it does a comprehensive glance of an important river basin in its bearing on the sanitary circumstances of the populations affected by it, has considerable local interest, and many of the questions he raises are also of wider than mere local concern.

On Diphtheria in the Rural District of Erpingham.—Dr. Gresswell, also one of the occasional inspectors of the Local Government Board, has presented to that Board another of a series of reports on diphtheria, the affected locality being Erpingham, in the north-east of Norfolk. There was a great epidemic of this disease in Erpingham in 1858, and fatal attacks have been off and on present there ever since; but in 1883 and 1884 there was a recrudescence, 28 diphtheria deaths being registered in addition to 4 from "croup," and a few others from allied throat affections. The population is now about 20,250, and the insanitary conditions discovered in the district raise a suspicion that it has undergone but little improvement during the twenty or thirty years since the first pestilential prevalence to the present date, and there seem grounds for believing that the persistence of diphtheria is intimately bound up with, if not directly traceable to, these insanitary conditions. One of the most interesting points discussed by Dr. Gresswell relates to the recurrence of diphtheria in particular individuals; and as to this, it is pointed out that an attack of the disease often appears to leave the tonsils in a condition in which they are, under the influence of cold and damp, particularly likely to put on a condition of activity and reproductiveness; and that the disease, dormant for a long time, is thus reproduced in an infective form. The poisons of syphilis, of ague, of relapsing fever, and perhaps of scarlet and typhoid fevers, are referred to as similarly causing recrudescences, and it is added that analogy furnished in the manifestations of cryptogamic protoplasm is in its favour. The conditions essential to this new life of diphtheria infection lying dormant in the individual are next discussed, and it is pointed out how certain damp, ill-ventilated, and mouldy dwellings may almost be regarded as "abodes" or "cultivating-grounds" for diphtheria. Whether these places supply the whole conditions requisite for maintenance of the material cause of diphtheria, or whether the persons themselves become, by reason of sustained habitation in such dwellings, exceptionally suitable "hosts" for the maintenance of the virus, is a matter on which Dr. Gresswell is not prepared as yet to express an opinion. The report is thoughtfully prepared, and it affords many highly suggestive hints which aim at explaining some of the most obscure points in connexion with the spread and recrudescence of diphtheria.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6169 births and 3850 deaths were registered during the week ending January 30th. The annual death-rate in these towns, which had been equal to 23·8 and 22·4 per 1000 in the preceding two weeks, further declined last week to 22·1. During the first four weeks of the current quarter the death-rate in these towns averaged 22·7 per 1000, which was 1·9 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 14·4 in Hull, 15·3 in Leicester, 15·9 in Derby, and 17·5 in Brighton. The rates in the other towns ranged upwards to 26·6 in Norwich and Plymouth, 29·6 in Blackburn, and 33·0 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding four weeks from 497 to 407, further fell last week to 360; they included 168 from whooping-cough, 75 from measles, 31 from diarrhœa, 29 from scarlet fever, 28

Digitized by Google

from "fever" (principally enteric), 23 from diphtheria, and 6 from small-pox. No death from any of these zymotic diseases was recorded last week in Wolverhampton, Derby, or Huddersfield; whereas they caused the highest death-rates in Portsmouth, Plymouth, Nottingham, and Blackburn. The greatest mortality from whooping-cough occurred in London, Portsmouth, and Bolton; from measles in Nottingham, Blackburn, and Plymouth; from scarlet fever in Birkenhead; and from "fever" in Newcastle-upon-Tyne and Preston. The 23 deaths from diphtheria in the twenty-eight towns included 13 in London, 3 in Liverpool, and 2 in Portsmouth. Small-pox caused but 1 death among the residents of London and its outer ring, 5 in Liverpool, and 1 in Nottingham. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had declined in the preceding eleven weeks from 70 to 26, had further fallen to 22 on Saturday last; 4 patients were admitted to these hospitals during the week, against 11 and 2 in the previous two weeks. The Highgate Small-pox Hospital contained 3 patients on Saturday last, one case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 534 and 477 in the preceding two weeks, were 478 last week, and were 77 below the corrected weekly average. The causes of 105, or 2·7 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Portsmouth, Birkenhead, and in three other smaller towns. The largest proportions of uncertified deaths occurred in Cardiff, Bradford, and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 23·9 and 23·1 per 1000 in the preceding two weeks, further declined to 22·4 in the week ending January 30th, but was 0·3 above the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 13·1 and 14·0 in Perth and Leith, to 26·5 in Glasgow and 26·9 in Paisley. The 363 deaths in the eight towns showed a further decline of 17 from the numbers in recent weeks, and included 13 which were referred to whooping-cough, 9 to scarlet fever, 7 to diarrhœa, 4 to "fever" (typhus, enteric, or simple), 3 to diphtheria, 1 to small-pox, and not one to measles; in all, 37 deaths resulted from these principal zymotic diseases, against 45, 40, and 36 in the preceding three weeks. These 36 deaths were equal to an annual rate of 1·5 per 1000, which was 0·6 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 15, 9, and 6 in the preceding three weeks, rose again last week to 13, and included 10 in Glasgow and 2 in Edinburgh. The 9 deaths from scarlet fever showed an increase upon recent weekly numbers; 6 occurred in Glasgow, and one each in Dundee, Greenock, and Leith. The 7 deaths attributed to diarrhœa corresponded with the number in the previous week, but were considerably below the average. The deaths from "fever" and from diphtheria showed a considerable decline on the numbers in the previous week; 2 from "fever" and 3 from diphtheria were returned in Glasgow, as was also the fatal case of small-pox. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 145 and 160 in the preceding two weeks, were 156 last week, and were 58 below the number in the corresponding week of last year. The causes of 80, or more than 14 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 28·8, 28·3, and 29·6 per 1000 in the preceding three weeks, rose again to 31·9 in the week ending Jan. 30th. During the first four weeks of the current quarter the death-rate in the city averaged 30·9 per 1000; the mean rate during the same period not exceeding 22·6 in London, and 18·6 in Edinburgh. The 216 deaths in Dublin last week showed an increase of 16 upon the number returned in the previous week, and included 15 which were referred to the principal zymotic diseases, against 15, 30, and 24 in the preceding three weeks, 13 resulted from whooping-cough, 1 from "fever" (typhus, enteric, or simple), 1 from scarlet fever, and not one either from small-pox, measles, diphtheria, or diarrhœa. These 15 deaths were equal to an annual rate of 2·2 per 1000, the rate from the same diseases last week being 0·6 in Edinburgh and 2·5 in London. The fatal cases of whooping-cough, which had been 8, 19, and 17 in the preceding three weeks, declined again last week to 13. The deaths from the other zymotic diseases were exceptionally few. Eight inquest cases and 6 deaths from violence were registered; and 84, or considerably more than a third of the deaths, were registered in public institutions. The deaths of infants showed a decline, whereas those of elderly persons were more numerous than in any recent week. The causes of 31, or more than 14 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ADMIRALTY. — The following appointments have been made: — Staff Surgeon Cecil Drake, to the *Britannia;* Surgeon Henry W. D. Welsh, to the *Defiance;* Surgeon George F. Wales, to the Plymouth Division of the Royal Marines; Surgeon John Hunter, to the *Tyne;* and Mr. John F. Conniham to be Surgeon and Agent at Capper.

RIFLE VOLUNTEERS. — 13th Middlesex (Queen's Westminster): — Acting Surgeon John Gascoigne Webb to be Surgeon; Hugh Webb, Gent., to be Acting Surgeon.

Correspondence.

"Audi alteram partem."

SURGICAL TREATMENT OF EMPYEMA.

To the Editor of THE LANCET.

SIR,—In Mr. Godlee's very interesting and instructive lecture (published in THE LANCET of January 23rd, p. 143), he states that "while after an empyema the dorsal curve is very long and occupies the whole dorsal region, in scoliosis we generally find a compensatory curve beginning at the lower part of the back. ..... The compensatory curves in the lumbar and cervical regions are shorter than those of ordinary lateral curvature, and there is much less rotation of the bodies of the vertebræ." With regard to rotation of the vertebræ, Mr. Godlee's observation of the fact that this condition does exist in curvature from empyema is worthy of note, for hitherto it has been nearly always written that rotation does not take place in curvature from empyema. In the "Surgery of Deformities," p. 166, however, I stated that in the cases of lateral curvature from thoracic disease which I had examined there existed distinct rotation of the vertebræ. This subject must possess importance not only as regards diagnosis from the general form of the parts, but also with respect to changes in the thoracic cavity, and the consequent modifications of the auscultatory and other signs. When there exists severe rotation the bodies of the twisted vertebræ approach more or less the internal surfaces of the ribs, and thus partly or entirely displace the lungs from this region. It is therefore important to recognise the fact of such rotation, and Mr. Godlee has doubtless done good service in recording his observations on this point.

As to the first parts of the above quotation from the lecture, I would remark that curves from other causes than empyema may assume the form described, and that the former vary to a much greater extent than is usually stated. In evidence of this statement I may remark that I once analysed sixty-eight consecutive cases of lateral curvature which I had had under treatment, and the curves were as follows: thirty-nine were sigmoid, twenty-nine were single curves, and in two of the latter there was no deflexion of the spinous processes, but rotation only of the vertebræ. Of the thirty-nine sigmoid, the dorsal curve was to the right in twenty-seven cases, to the left in twelve cases. Of the single curves, the direction was to the right in fifteen, to the left in fourteen cases. Thus, in the sigmoid the proportion of right dorsal curve to left was a little more than two to one, and in the single curves the proportion was nearly equal. Thus, the supposed typical form of lateral curvature certainly does not occur in so large a proportion of cases

Digitized by Google

as to warrant the common assertion that the dorsal curve is almost always to the right, and that there is in these cases always a compensatory curve to the left in the lumbar region. Many of the cases I refer to resembled, as regards the curve of spinous processes, the figure C shown in THE LANCET.

In recording my experience on this subject it has been my desire to add, if possible, to the value of Mr. Godlee's practical observations.—Your obedient servant,

Queen Anne-street, Jan. 1886. NOBLE SMITH.

A HINT ON THE TREATMENT OF RINGWORM.

To the Editor of THE LANCET.

SIR,—Last August a lady asked me to examine her nurse-maid's head. I did so, and found a well-marked patch of ringworm about an inch and a half in diameter. The mistress was naturally unwilling to expose to the contagion her children, who presented no sign of the disorder, and almost equally unwilling to part with the girl for a time. After some reflection I told her I thought the difficulty might be got over with only very slight risk to the children, and treated the case in the following way. Having cut the hair close to the scalp, all round the patch, I first painted it with an alcoholic solution of iodide of mercury—an old-fashioned but excellent remedy, obtained by adding calomel to tincture of iodine and using the supernatant colourless fluid. As soon as the slight soreness it produced had passed off, I applied an iodine plaster, obtained from a formula in Beasley's book and attributed to Roderburg, an ounce of the plaster containing half a drachm of solid iodine. This, spread on kid, was carefully applied to the patch, which it overlapped all round. At the end of a fortnight it was removed, and the ringworm appeared practically cured. To make sure, however, it was again painted with the above-mentioned solution and a fresh plaster applied for another fortnight. Upon being taken off, the whole surface of the patch was found covered with short hairs. No other patch has made its appearance upon the head or elsewhere, and not one of the three children, with whom the patient was in daily and hourly contact, took the complaint. Possibly the plaster alone would have been sufficient, but I thought it safer to use the paint in addition, and I feared that if I used a more powerful plaster the irritation might tempt the patient to remove it. I might also have used a plaster containing oleate of mercury, but doubted whether it could be made sufficiently adhesive. The advantages of this mode of treatment are obvious enough, for by its means the risk of the disease being spread by actual contact, by means of caps and by the common use of hair-brushes, is reduced to a minimum. I find no allusion to this method in the ordinary works on the subject, and therefore infer that, if not new, it is not widely known.

I am, Sir, your obedient servant,

Brixton-road, Jan. 1886. RALPH W. LEFTWICH, M.D.

LIPOMA OF THE MESENTERY.

To the Editor of THE LANCET.

SIR,—The rarity of solid or cystic tumours of the mesentery is well known by the fact that Sir Spencer Wells, whose experience in the domain of abdominal surgery is, I suppose, unequalled, had only met with two cases up to last year: one was a solid tumour of about the size of an adult head, which he successfully removed, and the patient made a perfect recovery; the other was cystic, and, though the operation was successful, the patient died about a month after its performance. The difficulty attaching to the diagnosis of these from other abdominal tumours is almost insuperable, and especially is it so at a time when they are of such a size as to be removable with a fair prospect of the ultimate recovery of the patient. The above remarks constitute my apology for bringing under your notice and that of your readers the following observations made before a meeting of the Société de Chirurgie of Paris by M. Terrillon, on the 13th inst.

M. Terrillon operated and successfully removed a large lipoma of the mesentery. The patient was doing well up to the fifteenth day, but after that date persistent diarrhœa set in and death took place on the thirty-second day after the operation.

The observation of this case caused M. Terrillon to institute researches into the history of these lipomas, of which the following is an epitome.

Sex.—They occur, according to published cases, about twice as often in females as in males.

Size.—They are often of considerable size, ranging in weight from 8 lb. to 62 lb.

Growth.—They are of rather quick growth, attaining the above-mentioned weight in about two or three years.

Development.—They start from the front or sides of the lumbar spines and insinuate themselves between the two layers of the mesentery, which becomes thickened and forms an envelope for them. The bulk of the intestines are displaced to the opposite flank, but in some cases the tumour is in intimate contact with a portion of the intestine, and difficulty is experienced in separating it therefrom, so much so that in one case the surgeon was compelled to resect a portion of the bowel in the course of the operation, and in M. Terrillon's case the intestine was injured during the dissection necessary for the removal of the tumour. Sometimes the tumour, whilst insinuating itself under the lateral peritoneum, displaces forwards and contracts adhesions with the ascending or descending colon; in such cases the large intestine would lie in front, as happens in tumours of the kidney, or it may be folded over to the opposite side, as was the case in the patient operated on by M. Terrillon. The occurrence of ascites is not frequent. Compression of the abdominal viscera, by the progressive increase in size of the tumour, causes the emaciation and cachectic appearance, which is followed by the death of the patient after a few years.

Symptoms.—As to the symptoms, they differ in no way from those of other abdominal tumours of slow growth. On palpation, a sense of false fluctuation is given. In females, as the tumour is often situated near the upper part of the pelvis, it appears to have a dubious connexion with the uterus and its appendages, and it has often been mistaken for an ovarian cyst.

Diagnosis.—Up to the present time the diagnosis has not been made in a single case before the operation or the autopsy, excepting approximately. In males various tumours have been suggested. In M. Terrillon's case he had given as his diagnosis "a solid non-malignant tumour of the abdomen, probably myxomatous"; this diagnosis was based on the absence of any substance in the exploring trocar. The soft consistence, simulating fluctuation, has often caused the surgeon to practise puncturing the tumour in the hope of finding contents of a fluid nature, but ordinarily this has shown nothing, or only a little blood.

Pathological appearances.—The pathological nature of the tumour varies within certain limits; sometimes it has been a pure lipoma, but often the microscope has revealed a mixture of myxoma and lipoma. In one case the fat had the appearance of tallow, and it was a question whether it was a steatoma. Finally, in a case observed by M. Péan, the mass had undergone partial calcareous or osseous transformation. Being ordinarily constituted by lobules of fat more or less separated by tracts of fibrous tissue, the lipoma is but slightly vascular in itself, but its connexions with the mesentery are full of large vessels, which render an operation very troublesome; they necessitate the employment of a large number of forci-pressure forceps and numerous cat-gut ligatures.

Removal of these tumours has always been difficult; it cannot be accomplished without separating them from the mesenteric covering which envelopes them, and to do this necessitates the division of numerous lymphatics and blood-vessels belonging to the mesentery, and laying bare the great vessels in front of the spinal column. From this one can form an estimate of the possible disorders which may follow this operation.

The anfractuous cavity left after this removal of the tumour with its flaps of mesentery is enormous, and from its walls there is copious exudation of fluids. In most of the cases it has appeared necessary to diminish the bleeding surface by resecting the more prominent of the flaps, or reducing their bulk by ligature. It has been attempted to drain this cavity, but without success. Almost always the abdominal wound has been closed as after an ovariotomy.

Mortality.—The mortality after operations of this kind is very high. It would seem to be principally due to the destruction of the mesenteric vessels interfering with intestinal absorption. The gravity of the operation may also be due to the unavoidable division of numerous branches of the great sympathetic plexuses. Many patients have died

Digitized by Google

soon after the operation from traumatic shock or exhaustion; others from acute peritonitis, both septic and aseptic. Finally, some have survived the operation for periods varying from ten to thirty days, and have then succumbed to various intestinal disorders. Amongst eight operations there has been only one averred success. The results so far are discouraging, but it is to be hoped that in the future, the diagnosis becoming more precise, we shall be able to operate at a more favourable time, when the tumours have not acquired so great a size, and that then the chances of cure will be more favourable.

Those who require to investigate this subject more fully may refer to the article on Lipoma by Cornil in the "Dictionnaire Encyclopédique des Sciences Médicales," to the "Traité de Pathologie Externe," by Follier and Duplay, and the "Traité des Tumeurs Abdominales," by Péan. Both of Sir Spencer Wells's cases are related in his work on the "Diagnosis and Surgical Treatment of Abdominal Tumours," pp. 204 and 205.—I am, Sir, yours obediently,

Jan. 1886. G. R. HAMERTON, M.D.

"A CASE OF TUBAL PREGNANCY."

To the Editor of THE LANCET.

SIR,—In reference to the case of supposed tubal pregnancy recorded by Dr. Hay in THE LANCET of Jan. 16th, whatever may be the true explanation of the condition, the theory propounded will gain nothing from reference to the case referred to as having recently been brought forward at the London Obstetrical Society, which on further examination by a committee of Dr. Herman and Mr. Doran was found to be wanting in any kind of corroborative evidence in favour of its supposed nature. There was no abnormality of the woman's pelvic organs to be discovered, and the specimen presented the usual characters of intra-uterine pregnancy (the decidua of which is quite different from the corresponding structures developed in all cases of extra-uterine gestation); there was, in fact, not one particle of evidence in favour of the strange story related.

The history of Dr. Hay's case, as given in THE LANCET, appears to be conclusive in establishing the fact that the fœtus expelled was intra-uterine at the time of examination, for the introduction of the probe was followed by hæmorrhage, and abortion took place three days after. The probability of the passage of a four-months' tubal pregnancy on two occasions into the uterus under the circumstances described is altogether incredible, the supposed gestation cyst being disconnected with the uterus; a dilatation of its tubal pedicle sufficient for the purpose is impossible. The diagnosis of tubal pregnancy is seldom correctly made; the condition is rarely suspected when it does occur, and when it is suspected it usually turns out to be a mistake, and the woman is fortunate who escapes abdominal section for what proves to be a normal intra-uterine pregnancy. I am, Sir, yours obediently,

Harley-street, Jan. 30th, 1886. WALTER S. A. GRIFFITH.

THE SCARLET FEVER OUTBREAK IN MARYLEBONE.

To the Editor of THE LANCET.

SIR,—I have read your article in THE LANCET of Jan. 23rd regarding an outbreak of scarlet fever in Marylebone, supposed to be caused by milk derived from a farm in this district, and must deprecate the publication by Mr. Wynter Blyth of a number of statements respecting a Hendon farm, the majority of which I have reason to know are based on conversations that Mr. Blyth had with Mr. Power and myself. I need hardly say that these conversations, the primary object of which was to protect London consumers from danger, did not contain all or nearly all the facts that are accumulating respecting the relations of milk and scarlet fever, and submit that the public should wait for Mr. Power's report, which will embody the results of our united investigations here, before arriving at any definite conclusion upon the matter under inquiry. Under the circumstances, I cannot but think that Mr. Blyth would have done well to confine his report to matters which came under his own observation in his own district.

I am, Sir, yours truly,

JAMES CAMERON, M.D.,

January 30th, 1886. Medical Officer of Health, Hendon.

BIRMINGHAM.

(From our own Correspondent.)

PRESCRIBING CHEMISTS.

THE Deputy Coroner, at a recent inquest on the body of a child nine months old, expressed his opinion that the question of prescribing by chemists might properly be taken up by the medical associations. There is no doubt that the custom is an evil one, and that a large business is done by prescribing over the counter. Considerable harm, especially to children, is the result of this practice. A sense of responsibility hardly enters with the recommendation to give certain medicines, which are promptly made up, and charged for accordingly. The poor and ignorant appear to accept the belief that a knowledge of compounding drugs is equal to the knowledge required in prescribing them. Certainly there is a vast amount of credulity among the British public in this respect, which affords an extensive market for this vicious practice. Until the law affecting unqualified practitioners is better defined and easier of application, these cases will still frequently occur, and reflect discredit upon the intelligence of those who are made the dupes, and very often the victims, of this mode of treating disease.

INGLEBY LECTURES.

On the 28th ult., the second of the two Ingleby lectures was given by Dr. Wade, before a large and appreciative audience, the subject being "Nervous Diseases of Women." The main characteristics of the two sexes were pointed out, and the subject of hysteria was carefully dealt with. The many and various symptoms were aptly illustrated from the lecturer's experience, while the known shrewdness and attention he has given to the investigation of this class of disorders allowed him to speak with force and authority. The usual vote of thanks was passed.

HOSPITAL SUNDAY FUND.

A project has been mooted to divide *pro rata* the proceeds of this fund among all the charities of the town. Hitherto the two largest—the General and Queen's Hospitals—have divided equally in respective years, and the fourteen amalgamated charities have taken one share. The manifest injustice to the Queen's Hospital, which is sadly in want of additional funds, allowed the matter, fortunately, to fall through, and thus the institution will be relieved of a great source of anxiety. The meeting of the General Committee of the Hospital Saturday movement was marked by the reports sent in from the representatives appointed to the various charities. These reports were unanimous in their testimony as to the efficiency and economy with which the charities are administered, and afford a practical commentary for the working population of the town. In the face of declining subscription lists in many directions, it is of importance that it should be recognised how the many may help the few; and while the suffering poor in the district come from the working class mainly, this movement exhibits clearly the forcible application of the widest charity being not only possible, but of the greatest service to fellow-workmen.

EDINBURGH.

(From our own Correspondent.)

NEW UNIVERSITY LECTURESHIP.

AT a meeting of the Senatus Academicus of the University of Edinburgh held last week it was decided to found a new lectureship on the Philosophy of Natural History in connexion with the natural history department, and Mr. G. J. Romanes, F.R.S., was appointed lecturer. The appointment is for five years, and it is announced that Mr. Romanes will give his first course of lectures, six in number, during next winter session. The lectureship has been endowed by a munificent bequest by Lord Rosebery, who was Lord Rector of the University from 1880 to 1883, and who has always taken the warmest interest in university affairs. This is the second lectureship which has been recently created in connexion with the natural history department, at the suggestion of Professor Cossar Ewart, the first being a lectureship on Comparative Embryology, on which subject one course

Digitized by Google

of lectures has been already delivered by Mr. G. Brook, F.L.S., the present incumbent. The new lectureship will prove a great boon to the University in many ways: by adding a widely-known name to the staff of teachers, by providing instruction on a subject of great importance at the present time, and by further developing the system of intra-mural extension, which can but have the most beneficial effect in widening the range of university interests. Mr. Romanes may feel assured of a hearty welcome in Edinburgh when he comes to deliver his annual quotum of lectures, and the number of those anxious to attend his course of instruction will be by no means a small one.

Edinburgh, Feb. 3rd.

ABERDEEN.

(From our own Correspondent.)

THE CHAIR OF PHYSIOLOGY.

DR. J. W. WILLIAM, Lecturer on Physiology in the London School of Medicine for Women, and Dr. Berry Haycraft, are said to be, as yet, the only candidates for the vacant chair in our University. It will, indeed, prove a difficult task to find a worthy successor to Dr. Stirling, whose removal to Manchester is a serious loss to the Aberdeen Medical School. An enthusiastic physiologist, a brilliant lecturer, a clear and fascinating teacher, he has done much to increase the reputation of the school.

MEDICAL JURISPRUDENCE AND HYGIENE IN NEW ZEALAND.

Dr. Frank Ogston has been appointed Lecturer on Medical Jurisprudence and Hygiene in Dunedin College, Otago, New Zealand. He leaves Aberdeen at an early date to commence his duties in May. Dr. Ogston has, during the last ten years or more, had large experience in medico-legal work, and in his new sphere of labour will, there is no doubt, do credit to his *alma mater* and the name he bears.

PHYSICIAN TO A HOSPITAL FOR FIFTY-FIVE YEARS.

Dr. Ogston, sen., the veteran medical jurist, lately resigned the office of physician to the Boys and Girls' Hospital in Aberdeen, an appointment which he has held for more than fifty-five years. For the vacancy there were five candidates. The final vote lay between Dr. Hall and Dr. MacGregor. Dr. Hall was appointed by the casting vote of the chairman.

Aberdeen, February 2nd.

IRELAND.

(From our own Correspondent)

CARMICHAEL SCHOOL OF MEDICINE.

ON Saturday last a general meeting of the lecturers and students of this School of Medicine was held for the purpose of forming a Medical Society, to be called the Carmichael College Medical Science Association, and for the election of office-bearers for the session. The chairman having briefly explained the objects of the meeting, the rules of the proposed Society were read and adopted. These rules provided that the papers to be read and discussed at the meetings of the Society should be solely on subjects connected with medical science, that the time for reading papers should not exceed fifteen minutes, and that the speeches of those who joined in the discussion should be limited to seven minutes and a half. Dr. Samuel Gordon was elected president, the teachers in the school vice-presidents, and Drs. N. Falkiner and McHugh honorary secretaries.

DUBLIN BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

The ninth annual meeting was held last week at the College of Physicians. The report of the Council referred to a resolution adopted at the previous annual meeting in reference to the condition of the Army Medical Department. Copies were sent to the Secretary of State for War and to the Director-General of the Medical Staff, and a communication was received by the chairman of the Parliamentary Bills Committee from the Permanent Under Secretary of State, stating that the only way in which the promotion to administrative grades could be expedited was to apply a more rigid system of selection, and that steps had recently been adopted with this view. The Council regretted this unsatisfactory reply, knowing that the system of selection referred to was ineffectual in relieving the block of promotion which still exists among the seniors of the executive ranks of the department. The Council had their attention drawn to what they consider a substantial grievance of Irish medical practitioners residing in England—viz., that under the regulations of the Local Government Board for England any practitioner desiring to act as public vaccinator in England must produce a certificate of having been instructed in vaccination at one of the educational vaccination stations named in the regulations of the Board, all of which stations are situated in England or Scotland. A letter in reference to this subject was addressed to the Secretary of the Local Government Board of England; but up to the present no communication beyond an official acknowledgment of its receipt has been received. The President-elect (Mr. Bennett) did not give the usual address, in consequence of a recent illness; and the office-bearers being elected for the ensuing year, the proceedings terminated. The usual annual dinner took place in the evening.

CHARITABLE BEQUESTS.

The late Mr. Francis Donagh, of the County Louth, has left £1000 to the Hospital for Incurables, £1000 to the Adelaide Hospital, £500 to the Rotundo Lying-in Hospital, and £500 to the Convalescent Home, Drogheda.

Dr. John Griffin has been appointed to the commission of the peace for the County Clare.

Dublin, Feb. 2nd.

BELFAST.

(From our own Correspondent.)

ULSTER EYE, EAR, AND THROAT HOSPITAL.

FROM the report presented at the last annual meeting we gather that during the year ending Dec. 31st last the number of patients treated at the hospital was 1977, of whom 1857 were new patients; of these 198 were admitted as intern patients; fifty-four of the patients were admitted as free; the rest were pay patients. Of the patients entered on the books of the extern department 1779 contributed to the funds of the hospital £52 4*s.*, and the remainder were free patients. The total receipts of the hospital from all sources was £562 0*s.* 9*d.*, and the expenditure £540 12*s.* 5*d.* During the past year the hospital has been open to students on operation days, and a large number have availed themselves of the privilege to attend.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

The annual meeting of the supporters of this hospital was held last week. During the past year 486 patients have been under treatment; the payments from those in a position to pay a small sum for medicine amounted to £27 3*s.* 6*d.* Dr. H. S. Purdon, to whom belongs the credit of instituting this hospital, has been elected a member of the consulting staff. While on the subject of consumption, we may state that the Throne Consumption Hospital, which has been largely endowed by the munificent generosity of Mr. Forster Green, is now in full working order, and Dr. James Lindsay has been elected to the post of physician.

THE BELFAST HOSPITAL FOR SICK CHILDREN.

From the report presented at the annual meeting of this the most popular of all the Belfast charities, we learn that during the past year 316 children have been under treatment in the wards, while in the extern department there were the immense number of 8974 new cases. Dr. Nelson has been appointed ophthalmic surgeon, and Mr. Andrew dentist. One of the speakers referred to the paragraph in the report calling attention to the fact that a large number of senior students of Queen's Colleges are receiving practical instruction at this hospital.

BELFAST MAIN DRAINAGE SCHEME.

A great deal of discussion is at present going on here in reference to the drainage scheme which has emanated from the Town Council, and on this subject one of our ablest engineers, Mr. Lanyon, has written with great weight. For several years past, especially during the summer, the inhabitants have been suffering from the foulest smells arising from the Lagan (our principal river), the Blackstaff,

Digitized by Google

and the slob lands on both sides of the Lough, these stenches being due to the deposit of sewage on the banks. The problem is how to get rid of this nuisance. By the new scheme it is proposed to discharge the whole of the sewage of Belfast and Ballymacarret at one spot on the slob lands on the county Antrim side of the Lough. Mr. Lanyon says this will cause a present increase of at least three times the nuisance, and thinks it preferable to let the sewage be chemically disinfected and deodorised, and the solid matter deposited and removed and sold as a manure; then a comparatively pure effluent can be discharged with safety into the new cut, where it will become thoroughly diluted and quite innocuous. It is to be hoped that, in the interests of the public health, no plan of drainage will be undertaken which will not thoroughly rid us of the present offensive nuisances, which are disgraceful to a city of such size and importance as Belfast.

NEW YORK.

(From our own Correspondent.)

HYDROPHOBIA.

THE annual hydrophobia scare has broken out in this vicinity with its usual severity. What gives this epidemic peculiar interest is the craze of the community to send all who have been bitten to Paris to be inoculated by M. Pasteur. The opportunity of testing the value of the inoculation or vaccination is peculiarly favourable. Several children in Newark were bitten at the same time by a dog supposed to be suffering from hydrophobia. Four of the children were immediately sent to Paris, where they were duly operated upon by M. Pasteur. The result of the vaccination was pronounced by him to be entirely successful, and the children have returned to their homes. They have been examined by their physician, who declares that they are in good health. The other children, two of whom were severely lacerated by the same dog on the same day, and who remained at home, are also well. It will be possible now to watch these two groups of children, and determine, possibly, the value of the vaccination.

DEATH OF PROFESSOR DRAPER.

The sudden death of Prof. John C. Draper will prove a great loss to the University Medical College, in which he was Professor of Chemistry. Dr. Draper was the eldest son of Prof. John W. Draper, and brother of Dr. Henry Draper, so eminent for his studies in solar and lunar photography. He was a writer of scientific works, the last of which, on Medical Physics, has just been published.

PUBLIC HEALTH.

The American Public Health Association has recently held its twelfth annual meeting at Washington. It was largely attended, and discussed many of the most interesting subjects in sanitary science. A prize had been offered by the Association for the best essay on School Hygiene; although a large number of papers were submitted, the prize was not awarded, none of the essays being deemed worthy.

PERILS OF PRACTICE.

A case of successful prosecution of a physician for an alleged error of diagnosis has excited much interest in this city. The physician is a reputable practitioner, and the patient a tradeswoman. The physician pronounced an eruption to be small-pox, and so reported the case to the health authorities, who had her removed to the small-pox hospital. The resident physician decided that she was suffering from eczema, and discharged her from the hospital. She recovered $500. It was proved on the trial that the defendant had called as counsel his father (a physician) and one of the inspectors of the Board of Health, both of whom corroborated his diagnosis. The profession is subscribing liberally to a fund to carry the case to the highest court.

New York, Jan. 16th, 1886.

IN view of the large consumption of pork and ham at Christmas time, the St. Petersburg Medical Society took the precaution just before the festive season of establishing two additional stations for the microscopical examination of pig meat in different parts of the city.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Members of the College on the 28th ult.:—

Browne, Oswald Auchinleck, M.B. Camb., George-street.
Limont, James, M.B. Edin, Newcastle-on-Tyne.
Prendergast, J. Moran, M.D. Royal University of Ireland, Victoria, Australia.

On the same day the following were admitted Licentiates of the College:—

Apthorp, East, Gurney-street.
Bartlett, Hedley Coward, Temperance Hospital, Hampstead-road.
Bennett, Frank Albert, St. Paul's-square, Birmingham.
Benson, Matthew, Wigan.
Billups, Percy Christopher Charles, Friern-road.
Bond, Barnabas Mayston, Granville-square.
Burd, Edward Lycett, Gray's-inn-square.
Burnett, Reuben, Onecote, Leek.
Candler, Wallace Harry Charles, Manor-park, Lee.
Cattell, George Trew, Crowhurst-road.
Clarkson, Thomas Harry Frederick, Heathcote-street.
Collingwood, Frederick William, Manor-road, Brockley.
Combes, Reginald Hare, Argyll-square.
Cottell, Reginald James Cope, Cheyne-row.
Counsell, Herbert Edward, Guy's Hospital.
Crisp, John, Kennington-park-gardens.
De Chazal, Edmond Lucien, Albert-street.
Dodd, Henry Work, Royal Free Hospital.
Drew, Arthur John, Gloucester-place, Hyde-park.
Edge, Frederick, Bury New-road, Bolton.
Evans, Oliver Conrad Penrhys, St. Bartholomew's Hospital.
Evill, Frederick Claude, John-street, Gray's-inn.
Ewens, George Francis W., Carey House, West Hammersmith.
Farr, Ernest Augustus, Andover.
Felix, Edward, Shirland-road.
Fountain, Edward Osborne, Hillingdon, Uxbridge.
Francis, Harry Arthur, Priory-road.
Freeland, Freeland John, Kingdon-road.
Freeman, Ernest Carrick, St. George's-square.
Frohwein, Otto Fraser, Portsea.
Gardner, William Thomas, Weddon House, Rosslyn-hill.
Gibson, John Hutchinson, Trinity-square.
Girling, John, St. Peter's-road.
Gostling, John Harry, Granville-square.
Green, Albert, Brickell-terrace.
Greenwood, Edwin Climson, Highgate-road.
Greig, William John, Bernard-street.
Harris, Herbert Elwin, Duncan-terrace.
Hazell, Robert William, Cape Town.
Hill, Alfred William, Vartry-road, Stamford-hill.
Hodge, Sydney Rupert, Fernleigh, Sunnyside-road.
Hope, George, Bramah-road.
Hulke, Frederick Backhouse, Admiralty House, Deal.
Hutton, John Stuart, St. Thomas's Hospital.
Jones, Edward Francis, Hyde Villa, Wrexham.
Jones, Hugh Edward, Trinity-square.
Jones, Thomas Slater, Trinity-square.
Jowers, Reginald Francis, Upper Vernon-street.
Kaka, Sorabji, Manekji, Whitehall-gardens.
King, Edmund Eleazar, Burton-crescent.
Le Quesne, Ferdinand Simeon, Blatchington-road, Brighton.
Liesching, Charles Edward, Elm-park-road.
Maggs, William Adolphus, Hanover-square.
Mandvivala, Fakirji Kavasji, Woburn-place.
Marder, Edward Swan, St. Thomas's-terrace.
Marriott, Henry Tancred, St. George's Hospital.
Martin, Francis George Clifton, Commercial-road.
Meaden, Edward Henry, Westfield-park, Bristol.
Morgan, Frederic James, Westminster Hospital.
Nixon, Edward John, Worcester, Cape of Good Hope.
Okell, John Bathurst, St. Thomas's Hospital.
Otway, Henry Carrol, Kennington-park-road.
Owen, Samuel Walshe, Landeroft-road.
Parsons, Frederick Gymer, Westfield, Lee.
Potter, Edward Furniss, Berners-street.
Reece, Richard James, St. Bartholomew's Hospital.
Reily, Alexander Yates, Charlotte-street.
Rigden, Alan, Brompton-road.
Rigge, John Arthur, Grays.
Roberts, J. Saunders Hughes, Royal Southern Hospital, Liverpool.
Russell, George Herbert, St. Bartholomew's Hospital.
Saunders, Mark Richard, Keppel-street.
Smith, Henry Craven, Fitzroy-street.
Staddon, Walter Joseph, Fentiman-road.
Staveley, William Henry Charles, Akerman-road.
Thomas, John, St. Peter's-street.
Totsuka, Kankai, Lambeth-palace-road.
Turner, Nathaniel Henry, Redcliffe-gardens.
Upham, Charles Hazlitt, De Vere Mansions.
Vincent, John Francis, Church-crescent, South Hackney.
Wacher, Sidney, Guy's Hospital.
Webb, John Bartlett, Leigh-road South, Bristol.
Weir, Frederick William, Dowry-parade, Bristol.
Wheaton, Samuel Walton, Church-terrace, Battersea-park.
Wilkins, Gilbert Hamilton, Brixton-road.
Williams, Thomas Henry, Seymour-place.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of

Digitized by Google

the College at a meeting of the Board of Examiners on the 28th ult.:—

Bateman, Robert Watering, L.S.A., Norwich.
Earle, Walter George, Barton-under-Needwood.
Webb, John Bartlett, L.R.C.P. Lond., Clifton, Bristol.

Admitted on the 29th ult.:—

Adams, Charles Edward, M.B. Lond., Buckhurst-hill.
Allen, Norman, M.D. Toronto, Toronto.
De Charzal, Edmond Lucien, L.R.C.P. Lond., Albert-street.
Ware, George Stephen, L.S.A., Berners-street.

Admitted on the 1st inst.:—

Adye, William John Alexander, L.S.A., Bradford-on-Avon.
Bartlett, Hedley Coward, L.R.C.P. Lond., Bishops Stortford.
Daly, Stephen Joseph, L.R.C.P. Lond., Ireland.
Greenwood, Edward Climson, L.R.C.P. Lond., Highgate-road.
Meaden, Edward Henry, L.R.C.P. Lond., Bristol.

COLLEGE LECTURES.—The annual course of lectures will be commenced on Monday, February 8th, at 4 o'clock, by Mr. John Bland Sutton, F.R.C.S., who will deliver three lectures, "On Evolution in Pathology." Professor Charles Stewart, M.R.C.S., will deliver six lectures, "On the Organs of Hearing," commencing on Monday, February 15th. Professor Alex. Hill, M.D., M.R.C.S., will deliver three lectures, "On the Brain Mechanism of Smell and Sight," commencing on Monday, March 1st. Professor Frederick Treves, F.R.C.S., will deliver six lectures "On the Anatomy of the Intestinal Canal and Peritoneum in the Mammalia." Professor Wm. Arthur Braily, M.D., M.R.C.S., will deliver three lectures, "On the Muscles and Fasciæ of the Orbit." The course will be concluded in June next by Mr. Leonard Charles Wooldridge, M.R.C.S., Professor Henry Power, F.R.C.S., and Professor William Cadge, F.R.C.S. The subjects of the several lectures will be hereafter published. The lectures will be delivered in the Theatre of the College on each Monday, Wednesday, and Friday, at 4 o'clock precisely.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following candidates have passed Part I. of the First Examination, recently held:—

†Augustus Henry Aldridge, Manchester; *Henry Andrew, St. Thomas's; *John Atcherley, Leeds; *Alfred Howell Atkin, Guy's; *Cecil Fowler Beadles, University College; William Edwin Bennett, Birmingham; William Pittillo Birnie, St. Bartholomew's; John William Bowd, St. Bartholomew's; †Charles Stanser Bowker, Middlesex; Arthur Mather Braund, Middlesex; *Charles Butler, St. Bartholomew's; Albert William Caporn, St. Thomas's; George Carolin, University College; Herbert James Carstairs, St. Thomas's; Raymond Theobald Cassal, University College; Isaac Cohen, Charing-cross; Robert Jacob Colmer, London; Charles Edwin Cornwall, St. Bartholomew's; *Willoughby Floud Cotton, St. Bartholomew's; Alfred H. Cresswell, London; James Meadmore Crocker, Leeds; Frederick Wm. Samuel Davies, Guy's; †Cecil Lacy Dawson, St. Bartholomew's; Robert Barsham Debenham, London; Robert Kingdon Ellis, St. Thomas's; Henry Luther Ewens, Bristol; Charles Edward P. Fowler, Bristol; Robert Houle French, London; Thomas William Francis Gann, Middlesex; †George Frederick Glinn, St. Mary's; †Frank Augustus Godfrey, London; Edward Milliken Goldie, University College; Harry Gordon, Manchester; James Gordon, Middlesex; *John Henry Porteous Graham, St. Bartholomew's; James Hake, London; Ernest James Hayford, St. Thomas's; John Grenville Henniker, St. George's; William Higgins, St. George's; Richard Hopkins, London; Gerald Sidney Owen Howes, Guy's; *John Christopher Hughes, Guy's; Walter Evelyn James, University College; *Morgan Jenkins, Guy's; H. Douglas Johns, Charing-cross; Henry Martyn Jordan, Guy's; Arthur Edwin Joscelyne, London; Luigi Walter Keiffenheim, Guy's; *James Keigwin Kempthorne, King's College; Fredk. Wm. Robert John King, Middlesex; Allan Ramsay Lacy, Guy's; George Herbert Lancashire, Manchester; *John Wesley Lloyd, Liverpool; Joseph Johnston MacGregor, St. Bartholomew's; H. Medland Manley, Guy's; Ferdinand Baptist Marin, Westminster; Charles Devereux Marshall, University College; †William Ernest Marshall, University College; Albert E. Martin, London; William Molesworth, Bristol; Percy Thomas Naden, Birmingham; William Roebuck Naylor, Leeds; William Anselm Odling, St. Bartholomew's; Oswald Osborne, London; William Penberthy, London; Herbert Lloyd Penny, London; †Frederick William Pogson, Leeds; George Leslie Howard Revill, Charing-cross; Austin Edward Reynolds, University College; †John Henry Roberts, Guy's; John Maurice Roberts, St. Mary's; Hougel Gough Rosedale, Guy's; *A. Lawrance Roth, Middlesex; Eusebius Rouse Rouse, St. Bartholomew's; Henry Ashton Rudyard, University College; Charles E. Russell-Rendle, St. Bartholomew's; Patrick Joseph Ryan, Private; Edward Rye, Manchester; Edgar Stanley Sanderson, London; James H. Sequeira, London; Edward Wm. Sharman, Guy's; Francis Odell Simpson, Liverpool; William Chearnley Smith, St. George's; Ernest R. W. Spratley, Liverpool; Frederick Chas. Spurgin, Middlesex; †Frank Henry Squire, London; *Percy Stainsby, Leeds; Thomas William Swales, Leeds; John Taylor, Manchester; J. Terry, St. Thomas's; Felix Tinoco, King's College; Herbert Vallance, London; Francis Henry Morgan Vanderpant, Charing-cross; Edward Yates Watson, St. Thomas's; Harry Watts, London; Frank Webb, Manchester; Frederic Hibbert Westmacott, Manchester; †James A. Whistler, St. George's; *Charles Horton White, Middlesex; Sylvester David Willard, St. Bartholomew's; Alfred John Williams, King's College; Robert J. Williams, London; †John Wood, St. Thomas's; Charles Samuel Woodd, St. Bartholomew's; Thomas Sanders Worboys, St. Bartholomew's; Walter Wright, St. Bartholomew's.

†Passed in Materia Medica, Medical Botany, and Pharmacy only.
*Passed in Chemistry and Chemical Physics only.

The following gentlemen have passed Part II. of the First Examination recently held:—

Joseph Brearley, Leeds; Charles Butler, St. Bartholomew's; James Meadmore Crocker, Leeds; Edmund Denison, Leeds; A. H. Venning Duckham, University College; †H. Hargreave Fawcett, University College; Emilien Edward Frossard, King's College; *Alfred Henry Grace, Bristol; Matthew Lewis Hughes, King's College; †Stewart Kirkpatrick, Liverpool; Henry George Lang, St. Bartholomew's; John Wesley Lloyd, Liverpool; Walter Douglas Macdonald, Guy's; William Hugh Macpherson, St. George's; Stephen Luther Martin, London; *Robert Henry Norgate, Bristol; *Carroll O'Sullivan, London; Edward Percy Paton, St. Bartholomew's; *Albert Edward Perry, Cork; Enrique Prada, King's College; †Herbert Fullarton Ransome, Manchester; *John Henry Roberts, Guy's; Harry Romer, St. Thomas's; James William Russell, Birmingham; Cyril Alexander Ryde, London; John S. E. Selby, St. Bartholomew's; Benjamin P. Viret, St. Bartholomew's; Leslie Herbert Walsh, King's College; F. Hibbert Westmacott, Manchester; †Augustus White, Guy's; Charles Williams, King's College; Robert J. Williams, London; John Wood, St. Thomas's; H. E. Worthington.

† Passed in Elementary Physiology only.
* Passed in Elementary Anatomy only.

BRITISH MEDICAL SERVICE.—The following is a list of Surgeons on Probation in the Medical Department of the British Army who were successful at both the London and Netley examinations. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list which follows:—

	Combined Marks.		Combined Marks.
*Yarr, M. T.	5911	Kendall, H. W. M.	4408
Mumby, L. P.	5570	Elkington, H. P. G.	4364
Melville, C. H.	5494	Gordon-Dill, R. C.	4324
Mills, B. L.	5356	Buchanan, J. B.	4314
Rayner, H.	5184	Skerrett, F. T.	4307
Genge, R. E.	5018	Adamson, H. M.	4301
Cardew, G. S.	5006	Ramsay, H. M.	4299
Renny, C. A.	4935	Lavie, T. G.	4299
Thiele, H.	4911	Rose, J.	4271
Cocks, H.	4905	Cox, R. H.	4226
Wilson, J. B.	4877	Brown, H. H.	4191
Lee, W. J.	4849	Corkery, T. H.	4150
Black, J. G.	4818	Locker, E. H.	4142
Kearney, J.	4790	Crooke, W. R.	4018
Hennessy, F. W.	4773	Squire, W. P.	3930
Saw, F. A.	4659	Walsh, C. L.	3923
Stokes, W. B.	4489	O'Donnell, J. J.	3922
Hall, F. W. G.	4181	Hayman, S. J. W.	3893
Kennedy, A.	4113	Hayes, J. P. S.	3730
Tate, G. S.	4410		

* Gained the Herbert Prize of £20, with the Montefiore Medal and Prize of 20 guineas, the Martin Memorial Gold Medal, and the Parkes Memorial Bronze Medal.

INDIAN MEDICAL SERVICE.—The following is a list of Surgeons on Probation in Her Majesty's Indian Medical Service who were successful at both the London and Netley examinations. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list which follows:—

	Combined Marks.		Combined Marks.
†Woolbert, H. R.	5976	Younan, A. C.	5417
Baker, G. H.	5618	Alcock, A. W.	5362
Grainger, T.	5594	Edwards, A. R.	5107
*Adie, J. R.	5487	Cadell, J. M.	4994

† Gained the Prize in Pathology, presented by Sir Joseph Fayrer.
* Gained the Montefiore Second Prize.

SOCIETY OF APOTHECARIES.—The following gentleman passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise, on the 28th ult.:—

Duckworth, Alfred, Eaton Bank, Accrington.

The following passed the examination in the Science and Practice of Medicine, and received a certificate to practise:—

Bateman, Robert Watering, Carlton-terrace, Norwich.

THE seventy-third annual meeting of the committee of the Clifton Dispensary was held on the 3rd inst.

AT the Parkes Museum of Hygiene on the 27th ult., Mr. F. B. Jessett, F.R.C.S., delivered a lecture on Preventable Diseases.

THE inaugural meeting of the National Health Society was held on the 29th ult., under the presidency of Sir Andrew Clark, Bart.

M. LEVRAT, agrégé of the Faculty of Medicine, has been appointed chief surgeon to the Hôpital de la Charité in Lyons.

THE annual winter entertainment to the patients of the British Home for Incurables was given on the 3rd inst.

Digitized by Google

TRICHINOSIS.—Five members of a family at Tarentum, Pennsylvania, are reported to have died of trichinosis. The lives of three other members of the family suffering from the disease are despaired of.

AT the annual general meeting of subscribers to the Dewsbury and District General Infirmary on the 28th ult., a highly satisfactory report was presented by the Board of Management.

PAPERS to hand from the colony contain lengthy accounts of the scare produced at Brisbane by the arrival at that port during December last of a cholera-infected ship. Energetic steps were at once taken to check the disease.

DURHAM COUNTY HOSPITAL.—A bequest of £10,000 has been added to the funds of this hospital, and new wings are to be erected to the memory of the donor, the late Mr. Eden, of Beamish Park.

Nursing Sisters S. Browne and E. Wright, attached to the Military Hospital at Woolwich, have each been presented with a medal for the Soudan with clasps for Suakim, in recognition of their services in the late Egyptian campaign.

PRIZE OF THE PARIS MEDICAL SOCIETY.—The Société de Médecine de Paris has awarded the Duparc prize, value 1200 francs, to M. Dalché, interne of the Paris hospitals, for his treatise on Ovaritis.

AT a general meeting of the Hospitals' Association, held on the 27th ult., the adjourned discussion on the subject of the "hospitals' out-patient" question was resumed. Several members joined in the debate, which appeared to excite great and general interest.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.—A public dinner in aid of the funds of this hospital will take place on Thursday, May 20th, at the Holborn Restaurant, when the Right Hon. the Earl of Rosebery, President of the hospital, has consented to occupy the chair.

THE first class of the Order of St. Ann has been given to Dr. D. E. von Wahl, Professor of Surgery in Dorpat, also the third class of the Order of St. Vladimir has been conferred on Prof. Lazarevich, the well-known obstetrician of Kharkoff.

MR. H. B. NOBLE has offered a large plot of land for the purpose of the erection of a new hospital for Douglas, Isle of Man, and also the sum of £5000 for the purpose of building it, on condition that the institution be called Noble's Isle of Man Hospital. The offer has been accepted.

THE PECULIAR PEOPLE.—A verdict of manslaughter was returned by a coroner's jury at Royston, on Wednesday, against a farm bailiff, living at Foulmire, near Royston. It was stated that the accused belonged to the Peculiar People, and that he declined to obtain medical aid for a child of his who died from pneumonia.

ON the 3rd inst. a Local Government Board inquiry was held at Harrogate, respecting an application by the urban sanitary authority of that town for permission to borrow money for, amongst other purposes, the construction of reservoirs for mineral waters. This scheme originated with the medical men of the town.

STOCKPORT AND DISTRICT MEDICAL SOCIETY.—The first meeting of this Society was held on Thursday, January 28th, at 6.30 P.M., at the George Hotel, Stockport, when rules were passed and the following officers elected:—President: Dr. John Howe (Marple). Vice-President: Dr. Henry Heginbotham (Stockport). Hon. Sec.: Dr. J. Johnson Bailey (Marple). Hon. Treasurer: Dr. Kenneth Maclean (Stockport). The members, numbering between thirty and forty, afterwards dined together under very gratifying circumstances.

BORDEAUX MEDICAL SOCIETY. — The Bordeaux Medical and Surgical Society has decided to offer its prize of 1000 francs for the present year for a monograph on Jacksonian Epilepsy. The Society wishes that all the information on the subject which at present exists in medical literature scattered in numerous journals, summaries, and papers should be gathered into one comprehensive work. The same Society offers another prize of the value of 500 francs, for a popular treatise on Alcoholism. The essays for both the above must be legibly written in French, and sent, with the names of the writers, in sealed envelopes, to the general secretary of the Society, before August 31st, 1886.

VACCINATION GRANT.—Dr. T. Lamont Macartney of the Worthen district of the Forden Union has been awarded the Government grant for efficient vaccination (second time).

HOSPITAL SATURDAY FUND. — The twelfth annual meeting of the supporters of this fund was held on the 28th ult. According to the report of the Council for 1885 the continued progress of the movement is evidenced by an increase of £500 in the awards to the participating institutions; £9500 had been awarded to 71 hospitals, 40 dispensaries, and 19 convalescent homes and charities. During the past twelve years £74,271 has been contributed to the hospitals through the medium of the fund. The receipts have advanced from £6141 in 1874 and £6150 in 1879 to £11,192 last year.

TEMPERANCE LEGISLATION.—The arrangements for the conference to be held on this subject on the 25th and 26th inst. are now complete. On the first day, after an address from the President, Sir Richard Temple Bart., papers will be read on the question, "What reform, if any, is desirable in the Licensing Laws?" and the remainder of the day will be devoted to a discussion of the question. On the second day papers will be read on the questions, "Should compensation be given on the compulsory extinction of licenses, and, if so, from what source?" and "Is prohibitory legislation desirable, and, if so, in what form?"

MANCHESTER MEDICO-ETHICAL ASSOCIATION.—The annual meeting of this Association was held on January 29th, 1886. The report of the committee showed continued prosperity, with a steady increase of members and funds. The following gentlemen were elected office-bearers and members of committee for the year:—President: Mr. F. H. Walmsley. Vice-Presidents: Drs. H. Ashby, W. H. Barlow, S. Buckley, and F. M. Pierce. Treasurer: Dr. D. L. Roberts. Secretaries: Dr. A. Wahltuch, and Mr. J. Broadbent. Committee: Drs. F. H. Collins, A. Emrys-Jones, S. H. Owen, T. C. Railton, E. Rayner, W. Walter, and S. Woodcock, and Messrs. G. Bowring, J. Foster, R. Dacre-Fox, A. Hodgkinson, and D. de Vere Hunt.

BOROUGH HOSPITAL, BIRKENHEAD.—The annual meeting of the governors of this charity was held on the 25th ult. The report stated that the total number of patients treated during the year ending Dec. 31st, 1885, was 9322, of whom 3842 were children. During the year 535 patients had been treated in the hospital wards, 1799 were casualties seen at all hours, the out-patients numbered 3240, the home-patients 2407, and the dental patients 1341. The total expenses for the year were £2655 4*s.* 7*d.*, and the total ordinary receipts £2258 12*s.* 2*d.*, showing that the receipts had thus fallen short of the expenses by £396 12*s.* 5*d.*, and, inclusive of the adverse balance against the institution brought forward at the beginning of the year of £260 19*s.* 6*d.*, left a balance due to the treasurer of £657 11*s.* 11*d.*

THE GERMAN HOSPITAL.—At the annual general court of governors of this institution, on the 27th ult., it was stated that the number of in-patients admitted to the hospital and to the convalescent home during 1885 was 1076 and the total number of out-patients treated at the institution and the dispensaries connected with it was 22,588. The receipts amounted to £9025 and the expenditure to £9163. Though nominally German, this institution opens its doors to patients of all nationalities, and the great majority of the accident cases, which form a considerable part of the whole number, are English. As will be seen by the above statement of accounts, the present income of the hospital does not cover its expenditure, and further funds are urgently needed.

JERVIS-STREET HOSPITAL, DUBLIN.—On the 27th ult. a ball of a very magnificent kind was held in aid of the funds of this institution, and was most successful, an immense number of tickets having been sold, while the citizens and tradespeople made liberal contributions. One of the new wards—140 feet by 30—was utilised for dancing, while two other main wards were used for the convenience of those present. The decorations were extremely handsome, and the building was illuminated by the electric light. It was in order to obtain the necessary funds for furnishing the new wards recently constructed that the ball was held. On Thursday, the 28th, there was a musical promenade and undress ball, on the following evening a promenade with military bands, and on Saturday a dramatic performance.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ATKINSON, T. R., M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Madley Division of the Dore Rural Sanitary District.

BARWISE, SIDNEY, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Second District of the Parish of Birmingham.

BENCRAFT, HENRY WILLIAM RUSSELL, M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer to the Southampton Workhouse, vice Robert Welch, resigned.

DAVIS, HENRY, M.R.C.S., L.S.A.Lond., Second Chloroformist to the Middlesex Hospital, has been appointed Anæsthetist to the National Dental Hospital.

ENGLAND, Mr., L.D.S.Eng., has been appointed Honorary Dental Surgeon to the Home for Female Orphans, St. John's Wood, W.

GIBBONS, ROBERT A., M.D., M.R.C.P., has been appointed Physician for the Diseases of Women and Children to the St. George's and St. James's Dispensary, vice Fancourt Barnes, resigned.

JACKSON, H., M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Barnstaple Rural Sanitary District.

KANE, JAMES R., M.B., C.M.Glas., has been appointed Medical Officer for the Third District of the Parish of Birmingham.

LUCAS, CHARLES, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Fifth District of the Newmarket Union.

MORRIS, DAVID W., L.K.Q.C.P.I., M.R.C.S., has been appointed Medical Officer for the Fulbourn District of the Chesterton Union.

NIVEN, JAMES, M.B., M.A.Cantab., has been appointed Medical Officer of Health for the Oldham Urban Sanitary District; and Medical Director and Attendant of the Westhulme Infectious Diseases Hospital, vice Hill, deceased.

ORCHARD, ALFRED, M.R.C.S. and L.R.C.P.Lond., has been appointed Medical Officer and Public Vaccinator for the Workhouse and Parish of Ashby-de-la-Zouch.

PAIN, T. D'OYLEY, L.S.A.Lond., has been reappointed Medical Officer of Health for the Kentchurch Division of the Dore Rural Sanitary District.

POCKLINGTON, EVELYN, M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Wimbledon Urban Sanitary District.

Digitized by Google

SHARMAN, JOHN, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Schools at Norwood of the Parish of St. Mary, Lambeth.

SHEA, JOHN, M.D.St. And., M.R.C.S., L.S.A.Lond., has been re-appointed Medical Officer of Health for the Wokingham Urban Sanitary District.

THAIN, LESLIE L., M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Longtown Division of the Dore Rural Sanitary District.

THOMAS, WILLIAM LANHAM, M.R.C.S., L.S.A.Lond., has been re-appointed Medical Officer of Health for the Horsham Urban Sanitary District.

WARTENBERG, VICTOR A., L.R.C.P.Ed., M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the St. Anne's-on-the-Sea Urban Sanitary District.

Births, Marriages, and Deaths.

BIRTHS.

ADAMS.—On the 1st inst., at 184, Aldersgate-street, E.C., the wife of John Adams, L.R.C.P.Lond., of a son.

ANDERSON.—On the 1st inst., at Spennymoor, Durham, the wife of Robert S. Anderson, M.B., of a daughter.

BENJAFIELD.—On the 6th ult., at Bletchenden, Church-street, Edmonton, the wife of W. B. Benjafield, M.D.Edin., of a son.

BROOKS.—On the 31st ult., at Beaumont-street, Oxford, the wife of W. Tyrrell Brooks, M.B., of a daughter.

CAMPBELL.—On the 29th ult., at Sheffield-gardens, Campden-hill, W., the wife of Brigade-Surgeon A. D. Campbell, M.D., of a son.

COLEMAN.—On the 29th ult., at Hill View, Streatham-common, S.W., the wife of Charles A. Coleman, M.D., of a son.

GABE.—On the 26th ult., at Mecklenburgh-square, W.C., the wife of John R. Gabe, M.D., M.R.C.S., of a son.

HILLIARD.—On the 3rd inst., at Church-street, Aylesbury, the wife of Dr. R. Harvey Hilliard, of a son.

POPE.—On the 26th ult., at Broomsgrove Villa, Goldhawk-road, W., the wife of H. Campbell Pope, M.D.Lond., F.R.C.S., of a daughter.

PORTER.—On the 29th ult., at Bow-road, the wife of J. Francis Porter, M.D., of a daughter.

RAYNER.—On the 1st inst., at Hanwell, the wife of H. Rayner, M.D., of a son.

SNOW.—On the 26th ult., at Norfolk-terrace, Bayswater, the wife of Herbert Snow, M.D.Lond., of a daughter.

WHITTLE.—On the 29th ult., at Oriel House, Prince's-avenue, Liverpool, the wife of Glynn Whittle, M.A., M.D.Cantab., of a son.

YOUNG.—On the 31st ult., at Rose Bank, Merton-road, Bootle, near Liverpool, the wife of T. Frederic Young, M.K.Q.C.P.I. M.R.C.S., of a daughter.

MARRIAGES.

BOTT—LUKE.—On the 27th ult., at Holy Trinity Church, Dartford, Kent, Joseph Bott, M.R.C.S., eldest son of Joseph Fennell Bott, late of Cammas Hall, White Roothing, Essex, to Elizabeth Ann, second daughter of William Luke, of Portsmouth, Hampshire.

COX—OLDREY.—On the 1st inst., at Kingston, Jamaica, J. Leslie C. Cox, L.R.C.P.Ed., L.R.C.S.Ed., to Florence Nugent, eldest daughter of the late Robert Oldrey, Esq., of Harpole Hall, Northamptonshire.

MILLIGAN—RICHARD.—On the 3rd inst., at 20, Grosvenor-crescent, Edinburgh, by the Rev. James MacGregor, D.D., assisted by the Rev. A. Wallace Williamson, M.A., of St. Cuthbert's, David Milligan, M.B., C.M.Edin., youngest son of the late James Milligan, Solicitor before the Supreme Courts, Edinburgh, to Margaret Isabella, second daughter of John Miller Richard, of Clarendon. At home, 7, West Maitland-street, 18th and 19th inst.

RICHMOND—JEFFERSON.—On the 28th ult., at All Saints' Church, Northallerton, Sylvester Richmond, M.D., of Greenhithe, Kent, to Mary, eldest daughter of W. T. Jefferson, Solicitor, of Northallerton.

WILLIAMS—BEVAN.—On the 2nd inst., at Christ Church, Lancaster-gate, by the Rev. C. Spencer Newham, Llewellyn Leonard Bulkeley Williams, M.B.Glas., son of the late David Williams, Esq., M.P., J.P., D.L., of Dendraeth Castle, Merionethshire, to Antonia Rebecca, daughter of the late William Bevan, Esq., of 74, Lancaster-gate, London.

DEATHS.

BALLS-WOOLBY.—On the 1st ult., at Groot River, Cape Colony, drowned whilst bathing in the sea, James Balls-Woolby, M.B.Lond., M.R.C.S., eldest son of R. J. Balls, of Spexhall road, Halesworth, Suffolk.

BUTLER.—On the 15th ult., at Coventry-street, Brighton, George Butler, Surgeon, A.M.D. (retired), aged 66.

HARRIS.—On the 26th ult., at Guilford-street, W.C., David Harris, M.R.C.S., aged 27.

KITCHING.—On the 2nd inst., at his residence, Enfield, Middlesex, George Kitching, M.D., in his 85th year.

RODGERS.—On the 30th ult., Professor Julian Edward Disbrowe Rodgers, M.R.C.S. and L.S.A.Lond., late of the London Hospital Medical School, in his 72nd year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, February 8.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Mr. J. Bland Sutton: Evolution in Pathology.
SOCIETY OF ARTS.—8 P.M. Prof. H. S. Hele Shaw: Friction (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Bernard Pitts: Subperitoneal Resection in certain cases of Acute Necrosis.—Dr. D. W. Finlay: On a case of Empyema with Cerebral Abscess.

Tuesday, February 9.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. R. Stuart Poole: Naucratis.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. J. Edward Squire: Enteric Fever at Suakim, with some cases of Malarial, Enteric, or Typho-malarial Fever.—Dr. Cayley: A case of Thoracic Aneurysm treated by the introduction of Iron Wire into the Sac.

Wednesday, February 10.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Mr. J. Bland Sutton: Evolution in Pathology.
HUNTERIAN SOCIETY.—8 P.M. Annual Oration by Sir Andrew Clark, Bart.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Rev. Dr. Dallinger will give his Presidential Address.
EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Dr. D. A. Gresswell: Chronicity and Rejuvenescence of Diphtheria in the Individual, and their Bearings upon Sustained Prevalence of Diphtheria in a Community.
SOCIETY OF ARTS.—8 P.M. Mr. Bennett H. Brough: Mining Industry at the Buda-Pest Exhibition.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown. Adjourned Discussion on Dr. Chalmers' paper on Puerperal Septicæmia.

Thursday, February 11.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. W. Chandler Roberts-Austen: Metals as affected by Small Quantities of Impurity.

Friday, February 12.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Mr. J. Bland Sutton: Evolution in Pathology.
CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Tyson: On three cases of Universal Alopecia.—Mr. Bellamy: An Obscure case of Femoral Hernia, operation, (?) double reduction *en masse*.—Dr. Hale White: Hysterical Pyrexia.—Dr. Goodhart: Cases of Meningitis of Obscure Origin.—Dr. Stephen Mackenzie: Two cases with Unilateral Paralysis of Tongue, Soft Palate, and Vocal Cord, &c. (living specimens).
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Prof. Osborne Reynolds: Experiments showing Dilatancy, a property of Granular Material, possibly connected with Gravitation.

Saturday, February 13.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. Archibald Geikie: The History of Volcanic Action in the British Isles.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

VOLUNTEER MEDICAL STAFF CORPS.

IN answer to inquiries repeatedly made to us, we may state that volunteer surgeons will find all the necessary information and instruction for training stretcher-bearers and bearer companies, the training of orderlies for the Medical Staff Corps, and other cognate matters, in the new Manual for the Medical Staff Corps, 1885, just published by the War Office, price 2s., and which can be had of Messrs. Clowes and Sons, Charing-cross, or any other large bookseller.

Medico.—"Gazzetta degli Ospitali" (two numbers weekly); Vallardi, Milano. "Il Morgagni" (monthly); Vallardi, Napoli.

Mr. G. Steel Scott, M.B.—The point should have been made clear in the original agreement. It cannot be enforced now, except by friendly argument.

PEAT SMOKE AND PHTHISIS.

To the Editor of THE LANCET.

SIR,—I should feel much obliged if you would kindly inform me whether you consider the inhalation of the fumes evolved during the combustion of common peat of any value in the earlier stages of tubercular phthisis. I am, Sir, your obedient servant,

Conservative Club, Feb. 2nd, 1886. J. R. S. TAYLOR.

*** We are not aware that "the inhalation of the fumes evolved during the combustion of common peat" is "of any value in the earlier stages of tubercular phthisis." Several years ago, Dr. Morgan showed that the immunity from phthisis enjoyed by the dwellers in the Hebrides and N.W. Scotland, who use peat fires, must be ascribed to the free ventilation of their huts, rather than to the peat smoke, which could be seen escaping from the door and crevices of the building (*British and Foreign Medical and Chirurgical Review*, 1860). Theoretically, such fumes would be antiseptic; but the solid particles they contain would by their inhalation increase the tendency to lung affection. An ample supply of *pure* air is the great prophylactic.—ED. L.

H. C.—We agree with our correspondent that such a mode of advertising is highly objectionable.

THE GENERAL LYING-IN HOSPITAL, YORK-ROAD.

To the Editor of THE LANCET.

SIR,—In your issue of last week the changes on the staff of the General Lying-in Hospital are incorrectly stated. Dr. Champneys is described as having been appointed physician to the Hospital. The facts are that Dr. Williams and Dr. Champneys have been physicians to the Hospital for the past five years; at the end of this time (Dec. 3rd, 1885) Dr. Williams resigned, and has been appointed consulting physician, and Dr. Herman has been elected to the vacancy thus created.

I am, Sir, your obedient servant,

Feb. 3rd, 1886. ANNIE WHYTE, Secretary.

WE are asked to state that the Secretary to the Royal College of Physicians of Edinburgh will be greatly obliged if the gentleman who kindly sent him a cutting from THE LANCET (posted from London, W., on Feb. 2nd) will do him the favour to communicate with him.

Mr. T. D. Harries, F.R.C.S.—It is left to the discretion of a magistrate whether he grants costs to a medical witness or not. It is usual to allow costs to medical witnesses called at the instance of the Treasury or the police, but not to those retained by the defence. The amount generally paid is half a guinea for each attendance; but recently a case occurred at a metropolitan police-court where the magistrate granted £1 12s. 6d. for five attendances of an expert witness.

R. C. B., M.R.C.S.—We know of no special work on the subject other than that mentioned.

Captain O.—Either of the two first-named places would be suitable.

SANTONIN AS AN EMMENAGOGUE.

To the Editor of THE LANCET.

SIR,—As the administration of santonin as an emmenagogue in chlorosis seems to be on its trial, the following case, though an isolated one, may be of interest.

A young lady presenting the usual symptoms—anæmia, pallor, and waxy hue of complexion, with cessation of menses, constipation, loss of appetite, foul tongue, palpitation and breathlessness on slight exertion, headache and depression of spirits—consulted me on Nov. 5th, and was prescribed a mixture containing ten grains of citrate of iron and ammonia, with three minims each of liquor strychniæ and liquor arsenicalis, and a grain of quinine in each dose, to be taken three times daily at meals in orange wine. I also ordered a pill containing two grains of extract of cascara sagrada (Schieffelin's), to be taken three times a day. This treatment was continued till Dec. 9th, by which time the patient's health was apparently completely restored, except that the menses had not returned. She had a healthy colour, was able to take a long walk, and enjoyed life again, feeling in perfect health. I then prescribed ten grains of santonin, to be taken at bed-time after a hot hip-bath, and on the day when it was reckoned that menstruation should recur. The only effect was that she spent a night of sickness and vomiting, and was extremely miserable all the next day, but was in her usual health the following day, when she described to me her symptoms, and added that she thought at the time that I had poisoned her. I resolved then to avoid emmenagogues, and advised her to continue the tonic mixture until the catamenia should appear. This happened four or five days later, when she was charitable enough to say that the medicine had had the desired effect. She has since continued in excellent health.

I very much doubt whether it is at all wise or rational to administer emmenagogues in chlorosis, and think that we should rely on constitutional treatment, regarding the cessation of menses as a symptom of the debilitated and anæmic condition. If the initial mischief be in the intestinal canal, where the blood is (so to speak) starved by the torpid condition of the digestive tract, or poisoned by the absorption of what should be excreted, the most essential part of the treatment is to restore regular and healthy action of the bowels. Cascara sagrada seems to be very effectual in this way. I have found that not all preparations of cascara sagrada are equally efficient. I prescribed quinine with the iron because I have repeatedly found that patients for whom I had occasion to prescribe quinine were unable to take it on account of the excessive menstrual flow which it caused; so that I regard a tendency to menorrhagia as a contra-indication for quinine, but I am not able to say with any certainty that it induces the flow when absent. The fact that quinine acts as an oxytocic, and that it has been sometimes blamed for causing abortion, seems to indicate that it does act through the nervous centres upon the ovaries and uterus.

I am, Sir, yours faithfully,

Jan. 25th, 1886. THEOBALD A. PALM, M.A., M.D.

To the Editor of THE LANCET.

SIR,—As much attention has lately been drawn to the use of santonin in the treatment of amenorrhœa, a few remarks upon it may not be out of place.

Santonin has apparently been used up to the present with a varying amount of success; but I think this is due to its not being continued for a sufficient length of time. Since the publication of Mr. Whitehead's article, I have used santonin freely in the treatment of amenorrhœa, and certainly have reason to be pleased with the results. In a record of seventeen cases there have only been two failures; in only one patient did the drug cause any unpleasant sensations—viz., dizziness, sickness, and headache; in none was there any disturbance of vision. In addition to the santonin, I usually prescribe mustard hip-baths, and a mixture containing some preparation of iron, combined with tincture of iodine and belladonna. Most cases of amenorrhœa that the practitioner treats are caused by anæmia. As the drug becomes more generally used and persevered in, I think practitioners will be pleased with the results. Whether the drug can be called an ovarian stimulant is, I think, uncertain; but that it produces a flow of blood from the uterus is beyond doubt. I have selected the following three cases as examples.

Margaret L——, aged thirty, married, had not menstruated since the birth of her last child, eighteen months. She had been subject to epileptic fits from girlhood. Within the last year the attacks were more frequent. After continuing santonin for six weeks, with an intermission of a week, menstruation occurred. A month after this, a flow appearing

Digitized by Google

two powders of ten grains each were given. Menstruation was restored, and has been regular ever since. The patient was being treated for the epilepsy at the same time, and has been quite free from fits for two months; formerly an attack occurred every fortnight.

Elizabeth B——, aged seventeen, under treatment for pericarditis, had never menstruated. The patient, who was very anæmic, had a leucorrhœal discharge. In this case no flow has been produced as yet; she is still taking the santonin, as well as remedies for the anæmia.

Annie G——, aged nineteen, a chlorotic girl in a very weak condition, had not menstruated for five months. After a fortnight's treatment with santonin and remedies for the chlorosis, menstruation occurred, the flow lasting three days. A fortnight later it returned in increased quantity, and lasted six days; since then menstruation has been quite regular, and the patient is now well.

In giving santonin a fair trial we must not use it alone, but combine its use with other remedies, according to the nature of the individual case; we must continue its use for a longer period before saying it has failed.

I am, Sir, yours faithfully,

Wooburn, Bucks, Jan., 1886. FRED. W. ALLWRIGHT, L.R.C.S.I., &c.,

"THE VENTILATION OF SEWERS."

To the Editor of THE LANCET.

SIR,—In THE LANCET of the 30th ult., under this heading an annotation appeared that left an impression, which may or may not have been intended, but which can scarcely be allowed to pass unquestioned. The possibility of low-level or surface ventilators, as *outlets* for foul gases, becoming disseminators of disease can hardly be gainsaid; and that the judgment of those who are not acquainted with the physical properties of gases and liquids should be fallacious, is not surprising; but are we to accept the judgment of those who are?

"There is only *one* way of effectually ventilating close (*sic*) drains and sewers, and that happily is an easy one." Taken together with some remarks further on the construction to be placed upon this is that sewers should be closed from source to mouth, and then "pipes, which ought to be not less than four inches in diameter, as perpendicular as possible ..... should be carried up from the drain or sewer to a point well above the level of the roofs, ... by means of these pipes the sewers may be properly ventilated." How is this ventilation to take place? Is the air to enter the sewers at Abbey Mills or Barking Creek (or in futurity at Canvey Island), and travel an unknown distance to the thousands of outlets formed by a multiplication of "the two or more ventilating pipes to be constructed by the spirited householder on his own premises"? or, is the physical fact lost sight of that ventilation, aeration, or oxidation (not merely vent to relieve pressure), requires an inlet within measurable distance of the outlet? The latter is the more probable, and confirmed by the enunciation that "the particularly ridiculous notion that pure air can be drawn in at the mouth of a low-level pipe, and foul air ejected at the open mouth of a high-level pipe, is probably one of the most mischievous and obstructive of prevailing misconceptions."

It would not be well to analyse this; but would it not be well to let it go forth from a scientific journal that for the ventilation of tubes—i.e., to maintain a current of air through them—both an inlet and an outlet are necessary, and that given a motive force, such as heat or the suction power of the wind, then a current will take place or not, and its speed be regulated according to the relative levels of inlet and outlet, and the ratio between the length and calibre of the horizontal and the length and calibre of the vertical pipe.

These are matters of calculation and experiment not yet elucidated, and by the medical profession, at least, should be treated in an unbiased spirit of inquiry.

I am, Sir, yours, truly,

JOHN F. J. SYKES.

Camden-road, N.W., Feb. 1st, 1886.

*** There are some undertakings so vast that the only way of achieving success is to grapple with them in detail. The immediate and practical business of the householder is not to ventilate the sewers of the metropolitan district as a whole, but to provide a way of egress for the gases which occur in the special length of drain and sewer with which his particular dwelling is connected—disconnected (?). This may be accomplished, as we have pointed out, by ventilating pipes, *two* or more at proper positions near his house. If short lengths of drain and sewer be thus ventilated, the difficulty of ventilating the sewerage of the metropolis generally would be greatly reduced. We are unable to accept as law the proposition laid down by our correspondent.—ED. L.

RISKS OF ABBREVIATIONS IN PRESCRIPTIONS.

A POLISH physician, wishing a patient to be dry-cupped in eighteen places, wrote the order with the figure "18" followed by the letter "b," to stand for the Polish word for cups. This, again, was followed by the word meaning "dry." The dresser, mistaking the "b" for "6," actually practised 186 dry cuppings on the unfortunate patient. The Russian journal from which we learn this incident, remarks that it is well that it was dry, and not wet, cupping that was ordered.

Mr. Montague W. C. Pulmer.—The man requiring the certificate should pay for it—at least, our correspondent's claim would be against him.

Mr. Treasdy's letter on the Royal College of Surgeons arrived too late for insertion this week.

RUSSIAN REMEDY FOR HYDROPHOBIA.

IN an article in the *Veterinarian* reference is made to a statement recently published by us respecting the alleged value of the alisma, or water plantain, as a remedy for hydrophobia. Our contemporary states that the late Mr. Youatt very early in his professional career gave trial to the alisma as a preventive, and also as a cure of rabies in the dog. A record of his experiments was published in 1829. Experimenting with the English *Alisma plantago*, Mr. Youatt recorded that it griped, purged, and produced some giddiness; but it did not prevent the appearance of the disease, or arrest its progress. He afterwards procured a little of the true alisma, but not in sufficient quantity to try its preventive power. Its curative efficacy was, however, tested. Two drachms of the powdered root, suspended in a little mucilage, were given to a rabid and ferocious dog. The animal became quieter, and after the administration of a second dose, six hours afterwards, its desire to do mischief altogether ceased; the harmless or paralytic stage of the malady supervened, and death occurred in twenty hours after the second dose. Mr. Youatt on other occasions tried the alisma procured from English herbalists, but without any satisfactory result.

THE USE OF SAYRE'S SWING.

To the Editor of THE LANCET.

SIR,—Allow me to call attention to certain objectionable features in the common method of using Sayre's swing for the application of poroplastic or plaster-of-Paris jackets. It is usual to suspend the patient both by the neck and by slings under the armpits, and the latter are supposed to add to the safety of the proceeding. I venture, however, to submit that the use of these arm-slings is inconvenient, unnecessary, and calculated to add to the danger rather than to diminish it. That it is inconvenient must have been felt by many who are in the habit of applying supports to the back; for the slings, if tight enough to assist in bearing the weight, are liable to cause unsightly elevation of the shoulders, and in the case of plaster-of-Paris jackets interfere with the smooth and even application of the material below the armpits. That it is unnecessary is, I think, sufficiently proved by the fact that I have now used the Sayre's swing hundreds of times without the arm-slings, with no more discomfort than is produced by suspension with them. That it is dangerous will, I think, be obvious from the following considerations:—So long as the patient keeps the arms down, part of the weight of the body is undoubtedly borne by the arm-slings; but directly the suspension becomes irksome, there is an instinctive tendency to throw up the arms, in order to grasp the cross-bar, whereby the arm-slings lose their hold and a sudden jerk is produced, the whole, or nearly the whole, weight being suddenly thrown upon the neck. Now, it is well known that sprains and dislocations most frequently occur from sudden and unexpected tension of particular muscles or groups of muscles; and I see no reason to doubt that what is true of muscles supporting the knee or the wrist is also true of those uniting the head and trunk. In either case a much greater strain can be borne with impunity when applied gradually and deliberately than when applied suddenly. Supposing the tension to be equally distributed at first in a patient weighing 9 st., the additional strain thrown upon the neck may be as much as 84 lb. Were the arm-slings firmly united by bands across the back and chest, the slipping might be partially, though not entirely, prevented; but, as far as I know, this is never done, and it certainly would be inconvenient to the surgeon. If the patient is allowed from the first to grasp the cross-bar, the arm-slings are useless, while the accompanying rotation and consequent prominence of the scapulæ necessarily leads to a misfit. That special cases may occur in which it is advisable to support in part from the armpits I do not deny, although I have not yet seen such. But I am convinced that in most cases it is far less dangerous to trust entirely to the neck muscles than to run the risk of slipping of the arm-slings, while suspension from the neck is a far more efficient means of extending and straightening the spinal column than any method depending upon support from the axillæ. In every case the greatest care should be taken to avoid sudden jerks to the neck, and it is also frequently advisable to accustom the patient to the process by a few preliminary suspensions of increasing duration on successive days.

I am, Sir, yours faithfully,

Moorgate-street, Jan. 12th, 1886. F. RUFENACHT-WALTERS, M.D.

NEW MEDICAL JOURNAL IN SPAIN.

THE appearance of a new Spanish monthly medical periodical dealing with the special departments of eye, ear, and throat practice is announced, entitled *Gaceta de Oftalmologia, Otologia, y Laryngologia*, and edited by Dr. Don Frederico Gomez de la Mata. There are at present some twenty medical journals published in Spain, about seven of which are weekly, the rest being trimonthly, fortnightly, and monthly. We have seen two ophthalmic journals, but have never heard of any specially devoted to ear and throat diseases; so that Dr. Don Gomez de la Mata has to a large extent an untrodden field before him.

E. W. is referred to the reply "Æsculap," *supra*.

LIP-READING.

A PAPER on Lip-reading, by Mr. William Van Praagh, appears in the first number of the *Quarterly Review of Deaf-Mute Education*. The great importance of lip-reading to our deaf children is felt by all workers for the deaf; yet, until now, lip-reading has not received so much attention as it ought to have had. Indeed, considering the subject of deaf-mute education historically, it is noteworthy how new in this country the subject is. It is not yet a hundred years since the first public institution for its promotion was established. At the beginning of this century that institution was the only one. Now, however, a very different condition of affairs has been arrived at; and we wish Mr. Van Praagh all success in the efforts he is making to ameliorate the condition of our deaf-mutes.

J. N. W.—1. For the post of police-surgeon, application should be made to the Chief Surgeon of the Metropolitan Police. The pay varies in the different divisions, and is regulated by the number of officers and men, each of whom contributes according to rank.—2. To the Home Secretary.

Rusticus.—A great deal of information and of forcible argument is contained in papers read at the International Medical Congress held in London in August, 1881, by Professor Virchow, Mr. Simon, and Dr. Fraser, reports of which will be found in THE LANCET of Aug. 6th and 20th, 1881.

M.R.C.S. had better refer to Pettenkofer's latest publication on the subject—i.e., "Die Cholera," Deutsche Bücherei, No. xxxvi. Breslau, Berlin, von S. Schottlaender.

Mr. R. Davison Pedley.—The matter shall have attention.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—I beg to call your attention to an error which I notice in the account of my experimental yellow fever, given in your issue of Oct. 10th, 1885, p. 680. The pyrexia observed by me after the successful cases of mosquito inoculations has never exceeded seven days' duration. This term should therefore be substituted in place of the limit, "twenty-one days," mentioned in your annotation. The rectification is so far important as the misconception might deter others from repeating my experiments. I am, Sir, yours truly,

Havana, Jan. 16th, 1886. CHARLES FINLAY, M.D.

Locum.—The question is not a medical one. But we do not see that the principal is ever afterwards bound to treat with B through A because he was first introduced to B through A.

Mr. S. W. Hambleton.—We do not quite see the drift of our correspondent's letter.

Octogenarian should consult his medical attendant in reference to the habit in question.

Mr. Annandale (Edinburgh).—Yes.

A Subscriber for Twenty-six Years.—The claim is a good one in a court of law.

Non-de-plume.—Yes, decidedly.

THE

Erasmus Wilson Lectures

ON

EVOLUTION IN PATHOLOGY.

Delivered at the Royal College of Surgeons.

BY J. BLAND SUTTON, F.R.C.S.,

ASSISTANT-SURGEON TO THE MIDDLESEX HOSPITAL, AND LECTURER ON COMPARATIVE ANATOMY.

LECTURE I.

CORRELATION AND ITS EFFECTS.

MR. PRESIDENT AND GENTLEMEN,—Darwin's greatest disciple in this country, Professor Huxley, has enunciated the principles of evolution in the form of three laws. 1. There has been excess of development of some parts in relation to others. 2. Certain parts have undergone complete or partial suppression. 3. Certain parts which were originally distinct have coalesced. Huxley uses the term "law" as a general statement of facts ascertained by observation. A good example for the illustration of these laws is the female generative organs. Many forms—e.g., the Cirrepedia, land mollusca, &c.—are provided with male and female organs constituting hermaphroditism. Ascending the scale of animated beings, we find that although every animal possesses at some period of embryonic life male and female organs in a potential form, yet normally one set, either those peculiar to the male or those peculiar to the female sex, gain the ascendancy. This serves as an illustration of the first law—that is, there has been an excess of development. Associated with this excess we find suppression and more or less complete disappearance of the opposite set of organs. Thus we obtain an excellent illustration of the second law. In the Icthyopsida (fish and batrachians) and the Sauropsida (reptiles and birds) the female generative ducts are for the most part represented by oviducts (Müllerian), quite separate, although in birds one usually disappears. In mammals the representatives of the oviducts fuse in the middle line through a greater or lesser extent, and constitute a median uterus. This illustrates the third law, or coalescence of parts originally distinct.

My object in these lectures is to endeavour to show that the structural aberrations of animal bodies of which pathological anatomy takes cognisance follow the same laws, which, when expressed in the terminology peculiar to that science, may be reduced to two: — 1. Correlation: (*a*) hypertrophy; (*b*) atrophy. 2. Coalescence.

Correlation leads to abrogation of functions and gives rise to rudiments; these rudiments or remnants may serve as the germs of origin of many forms of cysts and neoplasms. To anyone who has devoted serious attention to the matter it must be evident that the term hypertrophy has come to be used by pathologists, physicians, and surgeons in an exceedingly indefinite manner, to include almost any kind of enlargement of the organs, limbs, or bones of the body, without that careful attention necessary to discriminate between simple overgrowth, functional enlargement, or increased size, the result of adventitious elements in the part affected. True hypertrophy may be defined as "the enlargement of an organ beyond its usual limits as the result of increased function, or of some unusual condition of the corresponding or correlated organ." Before proceeding to discuss the question, it will be well to illustrate the definition with an example. Every known vertebrate normally possesses two kidneys, a right and a left one. In the case of the fowl whose left kidney is here shown, the right one had, from some cause or other, entirely disappeared. Nothing but the ureter remained to inform us of the previous existence of the associated kidney. Such a case as this is by no means rare; I have seen it in five instances in man, also in sheep, oxen, horses, and twice in birds. The important fact in these cases is this. In all instances of single kidney the size and weight of the persistent organ far exceeds the normal, and in the majority of instances is double the usual size. The kidney, in consequence of the loss of its fellow, has had to perform twice the amount of work usually required of it, and has doubled its bulk in consequence of this increased functional activity. Similar changes have been described in the lung, in the testicle, and other organs.

Let us now consider some examples of simple overgrowth as compared with true hypertrophy. Dermal organs supply us with many examples. In old bedridden females it is no unusual event to find the nail of the great toe enormously overgrown, and in texture as in appearance resembling a ram's horn. In animals living in confinement it is no unusual thing to find the hoofs three times their usual length, or the claws of birds enormously elongated. The beaks of parrots, peacocks, pheasants, partridges, &c., are extremely liable to this abnormal growth, on account of deficiency of usage. I have seen one of the claws of the two-toed sloth describe a complete circle. The same kind of excessive growth may also be studied in those mammals whose teeth grow from persistent pulps. From accidental displacement of the teeth in their sockets, or loss of antagonism from fracture of a tooth or of the jaw, the unaffected tooth or teeth will grow unduly, in some instances re-entering its own pulp chamber, or even describe two circles and a half. All such cases as these are loosely alluded to as examples of hypertrophy, but as a matter of fact they should be regarded as instances of simple overgrowth. These cases will occupy our attention later.

Bones are exceedingly liable to enlarge, and it is necessary to exhibit extreme caution in determining whether a given specimen is an example of hypertrophy or simple overgrowth, or enlarged as the result of inflammation. Very many cases described as hypertrophy are no more worthy of the designation than the enlarged sural muscles characteristic of that remarkable disease, pseudo-hypertrophic paralysis. The following will serve as a type specimen of what I consider true hypertrophy. An old man fractured his tibia, and, though he lived for ten years afterwards, the fracture never united. When he died the body came under my observation, and on dissection it was found that so far as actual thickness of the shaft was concerned, the fibula opposite the fracture had the best of it, for the tibia in the neighbourhood of the injury had undergone atrophy, but the fibula had hypertrophied, exceeding its normal thickness two and a half times.

In no structures of the body can hypertrophy be studied better than in muscular tissue, whether of the voluntary, involuntary, or cardiac variety. With regard to the heart, illustrative specimens are to be found in every pathological museum of any pretensions. The urinary bladder, when stricture of the urethra or calculus impede the free flow of urine, submits to this salutary process. The same changes may be seen in the gall-bladder; and the various stages of hypertrophy may be traced with great precision in that remarkable mill of many birds, the gizzard.

Corns are interesting examples of hypertrophy resulting from intermittent pressure, and their anatomy is well known. There are one or two varieties of epidermal thickening which occur in animals, well worthy a few moments' notice. In some monkeys, especially the group Cynomorphæ, which includes the baboons and macaque monkeys, there exists over each tuber ischii a naked pad of dense callous skin known as the ischial tuberosities, upon which the body rests when in a sitting posture. Now, a corn upon the hand or foot is a pathological production beyond dispute; ischial callosities are in structure as well as in function, corns. Ischial callosities differ from corns only in the fact that they are inherited; but, as I shall take occasion to show later on, pathological defects may be inherited as well as any other peculiarity, and hence the view is forced upon me that ischial callosities are pathological productions which have been transmitted so as to become race peculiarities. This opinion is materially strengthened by the fact that dogs, cats, and other carnivora possess five corns in the shape of callous pads on each of their paws, and under the influence of spinal cord lesions these callous pads may become the seat of a perforating ulcer.

Up to this point, we have chiefly devoted our time in indicating the points which guide us in distinguishing simple overgrowth from true hypertrophy; we must now consider the relation, often of the most intimate kind, which exists between hypertrophy and atrophy. It is a thoroughly established physiological fact that those organs which are

Digitized by Google

in most constant demand are richly supplied with blood; hence function and blood-supply are inseparably united in producing hypertrophy. This was well illustrated in the case of the kidney first considered; the right one having disappeared, the work of purifying the blood has now to be performed by one kidney, which, in consequence of increased work and increased blood-supply, hypertrophies to meet the requirements of the organism. Thus there has been a diversion of the nutrient stream, and this is largely brought about by the extreme plasticity of the arteries. Coincident with the enlargement of an organ, the nutrient arteries undergo commensurate development, and lead still further to a diversion of the nutrient stream, which in many instances is detrimental to some other organ. We all bear in our legs a striking example of the truth of this statement. In man the tibia as compared with the fibula by weight is as four to one; if sections be made of the leg of a fœtus at the third month, it will be seen that the transverse section of the fibula is not very much smaller than a corresponding section of the shaft of the tibia. If we examine the legs of menobranchus, who simply uses its legs as paddles, we find the two bones of equal thickness; but when the water animals began to take to the land, the weight of the body was far more conveniently transmitted to the ground by one bone than two, the increased function led to increased blood-supply, and the tibia grew in size—in fact, hypertrophied. The hypertrophy of the tibia, by causing diversion of the blood-stream, leads to atrophy of the fibula—at least, that is how my study of the question leads me to decipher the matter. Nevertheless, so truly does the fibula obey the great law of "heredity," that in the fœtus it does its best to indicate to thoughtful minds its former eminence. We must also remember that in aquatic mammalia the fibula is often no mean rival of the tibia. The relation which exists between hypertrophy of one organ and the atrophy of some associated organ may be conveniently termed "correlation;" and I shall now adduce evidence in support of an opinion that the division of animals into those that are males and females is a consequence of this remarkable law.

Many anatomists are of opinion that hermaphroditism is the primitive condition of the sexual organs. Hermaphrodites are found in every group of the animal kingdom, but, except in some of the lowest forms, self-fertilisation is wholly exceptional. Concerning this matter Darwin makes the following observation: "Turning for a brief space to animals, various terrestrial species are hermaphrodites, such as land mollusca and earth-worms; but these all pair. As yet I have not found a single terrestrial animal which can fertilise itself." The rule in hermaphrodites appears to be this—the male organs in one animal are used to impregnate the female organs of another, or *vice versâ*. From this arrangement it would easily come to pass that if one animal used the male portions of its reproductive organs more freely than the female parts they would, as a result of increased function, hypertrophy. In the first portion of this lecture I emphasised the fact that any marked degree of hypertrophy in one organ, nearly always leads to dwarfing of the correlated organ or set of organs; hence, in the example considered the female portions of the hermaphroditic organs remain dwarfed or *in statu quo*. This peculiarity would in the natural course of events be transmitted to the offspring, until at last the differentiation attains such a high degree that unless hypertrophy of one set of organs occurs in each individual propagation is impeded. Evidence on this point is afforded by the ontogeny of any mammal. Whilst the two sets of reproductive organs, male and female, up to a certain point maintain the same degree of growth, it is impossible to determine the sex of the embryo. As soon as one set begins to enlarge at a greater rate than the other the sex becomes pronounced. The remaining organs may eventually disappear or exist in such a rudimentary condition as to be discerned only by the most diligent search. In the invertebrate form Myzostomum, which occurs parasitic on the arms of feather-stars, the majority are hermaphrodite. It has recently been discovered by Dr. von Graaf, whilst working over the *Challenger* Myzostomida, that in certain species which occur in pairs in single cysts, one would have the male organs only functional, the other the female, and it is possible to trace every stage from typical hermaphrodites up to forms where the individual may be classed as a male or a female. Somewhat analogous conditions were detected by Darwin in the case of the Barnacles, but the conditions in these animals are even more remarkable than in the Myzostomida, for the males in this case are minute animals attached to the female, and often difficult of detection. In these complemental males the entire organism is modified for sexual function, for, as Darwin describes it, there is no mouth, no stomach, no thorax, no abdomen, no appendages, no limbs of any kind, yet all these parts are represented in the female. It seems to be simply a bag of spermatozoa, furnished with a few muscles, an eye, the pupal antennæ, and a probosci-formed penis, which, when uncoiled, is equal to eight or nine times the length of the animal! Darwin's observations have recently been confirmed by Prof. Hoek's observations on the Cirripeds collected by the *Challenger*.

Among mammals, the most striking examples of the peculiar value of hypertrophy are the curious malformed generative organs which occur in the cattle known as "free-martins." Hunter carefully investigated the condition of the reproductive organs in these cases; and the valuable dissections he made, now in the Hunterian Museum, are striking monuments of his investigations in this matter. Careful comparison of the detailed descriptions of the dissections of these malformations, and similar cases in sheep and goats which have come under my observation, show most conclusively that in these cases we have to deal, not with any one malformation common to all examples of free-martins, but rather with instances in which both sets of organs have attempted to attain a functional condition, with the result that both have failed to reach it. In some cases the Wolffian ducts have advanced many stages towards making a fairly complete set of efferent ducts for the testicles, and the calf approaches somewhat to a bull calf. In other instances the Müllerian ducts have made greatest progress, and a diminutive uterus can be made out, and in this case the calf most resembles a cow calf. Between these extremes there is every gradation and variation. Similar cases occur in fishes, reptiles, amphibians, birds, &c. I have seen many cases, and numberless instances have been recorded out of curiosity. They show most conclusively how impossible it is for both sets of reproductive organs to attain a functional condition in the same individual. Hypertrophy of one set must arise, and establish pre-eminence over the other.

The facts on which the argument rests that hypertrophy is one of the causes of division of sexes may be summarised as follows: — 1. In the lowest forms of animal life hermaphroditism is the prevailing condition. 2. Cross-fertilisation in hermaphrodites is the rule, and may, as in some of the Myzostomida, lead to a division into sexes within the limits of a single group. 3. Sporadic cases of adult hermaphroditism are far more common in the lowest forms of life. 4. If in mammals both sets of organs grow concurrently, the individual is sterile. 5. Both sets of organs grow equally to a definite period in embryonic life. 6. Reproduction in vertebrata, so far as is known, is impossible unless hypertrophy of one set of organs occur.

Among other remarkable examples of the wonderful correlation which exists between hypertrophy and atrophy must be mentioned the disappearance of gills in all forms above the Ichthyopsida (fish and amphibia). Balfour has pointed out that the allantois can be regarded in no other light than that of an enormously hypertrophied urinary bladder, which, having become a vascular sac, assumed the function of respiration in the embryo. Hypertrophy of one organ or set of organs leads invariably to atrophy of some other organ. Before the work of embryonic respiration was performed by the allantois, many and various contrivances existed for the performance of this important function—e.g., by means of external gills, the tail, and vascular adhesions of the yelk sac; but when once a functional allantois appears on the scene, all these methods are rendered obsolete, and gills for ever disappear.

It is to be hoped that the examples of what should be considered as hypertrophy, as compared with simple overgrowth, have been sufficiently convincing to impress upon my audience the importance of the distinction. Viewed in this light, hypertrophy shows itself to be a process of extreme beauty, utility, and interest, especially so when we reflect that the same process which enables one kidney to recompense the organism for the loss of its fellow is only an instance of the method by which the tibia has outgrown the fibula. The disappearance of gills in all forms of vertebrates above Ichthyopsida (fish and batrachians) has been brought about by the allantois. The division of reproductive labour, the institution of sexes, and many other equally important results, are the effects of the

Digitized by Google

indisputable correlation which exists between hypertrophy and atrophy.

Let us now proceed to consider certain examples of simple overgrowth, which appear to have been transmitted so as at length to become race characters. In no structure is this so admirably studied as in the teeth of mammals. I have already referred to those instances of teeth which grow from persistent pulp, and from lack of antagonism occasionally exceed their normal dimensions many times, describe circles, re-enter their own pulp chamber, or even penetrate the skull of their owner and bring about death. One of the most remarkable forms of dentition among mammals is that of the babirussa. The extraordinary canines of this animal have afforded plenty of scope to imaginative minds to account for their strange mode of growth. These teeth grow from persistent pulps, and from some cause or other the upper and lower canines failed to antagonise each other, and in consequence became enormously elongated. This abnormality frequently recurring, the peculiarity became transmitted to the offspring, eventually becoming perpetuated as a common feature in the males of this particular species. This isolated case does not carry much weight, but it must be remembered that in all members of the pig family, the common boar, the peccary, the wart hogs, the hippopotamus, as well as the babirussa, the canines have a great tendency to overgrowth and to describe circles. Thus in the wild boar the upper canine is slightly curved; in the wart hog its curve is very extensive, and clears for some distance the upper lip; whilst in the babirussa the curve is so exaggerated as to *pierce* the upper lip. Hence the careful consideration of these facts forces me to the conclusion that these peculiar canines were brought about in the first place as an example of overgrowth due to loss of antagonism, and the defect has been transmitted to the offspring. The remarkable teeth of the mesoplodon, the narwhal, and other of the cetacea are probably examples of the same process. [Lastly, when considering hypertrophy, it was shown that this process led to dwarfing of other organs associated with the enlarging organ, in that it led to diversion of the nutrient fluid.] This is well shown in the teeth; for in all cases the teeth which are immediately adjacent to these overgrown examples are, as a rule, the smallest functional teeth possessed by the animal, and in very many cases they fall out early, and in some instances are suppressed whilst yet embryonic, and never appear above the gums.

Introductory Lecture

TO THE COURSE OF

CLINICAL THERAPEUTICS.

Delivered at King's College Hospital.

BY I. BURNEY YEO, M.D., F.R.C.P.,

PHYSICIAN TO THE HOSPITAL, AND PROFESSOR OF CLINICAL THERAPEUTICS IN KING'S COLLEGE.

(*Concluded from page 238.*)

ANOTHER valuable observation in practical therapeutics derived from the clinical method is the necessity, in many instances, when we desire to produce diuresis, to combine together two or more diuretic remedies: give them singly, and you fail to produce any diuretic effect; combine them together, and free diuresis may be produced. Dr. Long Fox has alluded to this well-known fact in his suggestive paper on the "Action of Diuretics," read at the last meeting of the British Medical Association, and he concludes his paper with these words: "In most cases the union of remedies that cause a flow from the glomeruli with those that excite activity of the renal cells leads to a more complete depuration of the blood; and herein, again, we may give honour to our predecessors, in that they discovered by observation (by the clinical method) what we now are able to explain physiologically."

I might instance numerous other facts of a like nature, but I prefer quoting to you a sentence from Dr. Wilks' address at the last annual meeting of the British Medical Association, because it seems to me to express with complete accuracy the true relations of therapeutics to practical medicine. "It might be worthy to remark," he says, "how treatment accompanies and follows pathological discoveries, *in opposition to the mistaken idea* which many seem to hold, that there is a science of therapeutics gained by simple observation of the action of drugs on the body. It is sometimes said that therapeutics stands still or lags behind other departments of medicine. I think this is not true, and cannot be true; in fact, *I am at a loss to know what pure therapeutics is apart from disease and pathological states.* It seems to me it is the study of external agents on various diseased conditions, and it is not so much new remedies, but a better indication and knowledge of how and when to use them, which is required." It was a source of great satisfaction to me to find so philosophical a physician and thinker as Dr. Wilks expressing with so much point and force the very same views which were in my own mind.

The same thought seems to have been in the mind of Sir Wm. Roberts, of Manchester, although he approaches the subject from rather a different point of view, for in his address on the section of Therapeutics at the same meeting he pointed out the error of attempting to base our investigation of dietetics exclusively on the physiology of digestion and nutrition. He says: "I doubt if this is always, or even generally, the best starting-point. There are problems in human dietetics which appear to be beyond the reach of physiological research." I can illustrate this remark of Sir Wm. Roberts by some observations that I have often had occasion to make, and which could only have been the result of the clinical or practical method.

You will not very infrequently encounter, in treating cases of typhoid fever, especially if you are too much addicted to the use of an exclusively mild diet, that every now and then the patient has attacks of intestinal pain accompanied with large semi-solid motions consisting almost entirely of curd of milk. I have seen this several times in children, and occasionally, but less frequently, in adults. Sir William Jenner called attention some years ago to the same fact. So that in cases of typhoid in some patients milk is by no means the perfect food it has been represented to be. I have long been in the habit of giving to such patients whey, which I usually have rapidly prepared by boiling milk with a little lemon-juice, and flavouring with a little grated lemon-peel and straining. I have several times, also, encountered persons to whom eggs in any form, and however disguised or mixed with other food, were absolutely intolerable, and invariably caused digestive disturbances. Quite recently I have had occasion to observe the excellent effects of a diet composed almost exclusively of butter-milk in some of the most severe and protracted cases of intestinal dyspepsia. The hint first came to me from the practice of Dr. Mezger of Amsterdam, the celebrated advocate of massage for the relief and cure of various chronic maladies. He told a patient of my own that whenever he himself became the subject, as he occasionally did, of severe gastric catarrh, he took no medicine, but simply restricted himself wholly to butter-milk for a fortnight, and he was always cured. My own patient certainly derived the greatest possible advantage from this diet, and was able to accomplish far more work, intellectual and physical, than on any other system of feeding. Another case in which it has proved of great use and efficiency is one of locomotor ataxy, with severe gastric crises. In this case the gastric crises have disappeared with this regimen.

There is another curious observation it has occurred to me to make in connexion with the disturbing influence of tea on digestion. You will find that certain persons can at certain times take tea in moderation without its producing any disturbing effect on their digestive processes, while at other times its use leads to much distress and discomfort, causing annoying palpitation and an uneasy sensation often amounting to actual pain about the upper part of the cardiac region, generally on the left side. Now you will find that this difference in their capability of tolerating tea is often dependent on some emotional disturbances of the nervous system; the instant there is any worry or anxiety or mental uneasiness tea will at once disagree with such persons, and when the emotional wave has passed by and a condition of nervous calm has been re-established, the use of tea can be resumed. It is often important to be able to recognise this disturbing influence of tea and coffee, especially on cardiac innervation, and particularly in the production of that peculiar præcordial pain which I have

Digitized by Google

described above, and to which I am not aware that attention has been previously called. A gentleman, a neighbour of mine, the subject of aortic regurgitant mischief, called one morning just after his breakfast, complaining of most distressing palpitation. His pulse was beating 200 to the minute, and his heart was thumping distressingly against the chest wall. Having inquired into the particulars of the attack, I said to him, "You are poisoned by tea or coffee"; and then he told me that, contrary to his usual habit, he had taken a quantity of both strong tea and strong coffee at his breakfast. Once warned, he never did so again, and so avoided a return of the attack.

It has also occurred to me to make another practical observation with regard to the influence of different wines, especially on gouty persons. You will find that with such persons the wine which most rapidly and most freely stimulates the renal secretion is the wine which will agree best with them. With some persons it is champagne, with some it is claret, and with some hock; but with all, the wine that fails to promote diuresis will almost invariably do them harm. I was staying one autumn with a friend at his châlet in Switzerland, when he paid a visit to an old wine grower in the neighbourhood for the purpose of buying some of his wine; the old man, speaking in commendation of some particular vintage, said, as the highest praise he could think of, and in words which sound coarser to us than they do to a French-speaking people: "Vous buvez une bouteille, et vous pissez une bouteille." Thus bringing the testimony of a long experience to the corroboration of the fact I have stated.

I have just mentioned the word "massage," and that suggests an allusion to another undoubtedly great gain to practical therapeutics arising purely from the clinical method of observation. I believe massage is destined in the future to play an important part in the treatment of chronic maladies. To Dr. Weir Mitchell of Philadelphia we are greatly indebted for informing the profession of the extraordinary value of this method of treatment in certain nervous maladies, and especially in cases of so-called neurasthenia. To Dr. Wm. Playfair we are also indebted for adopting and following up Dr. Weir Mitchell's suggestions, and with eminent success. Dr. Mezger of Amsterdam has acquired more than European celebrity by the very remarkable results which, in his hands, have followed this method of treatment. I shall hope in some future lectures to describe to you fully this mode of treating chronic maladies, and to indicate the cases to which it is most appropriate.

And here let me warn you against hastily and ignorantly hurling the word "quackery" at every mode of treatment which you may yourselves be indisposed to carry out, or with the *modus operandi* of which you may be unacquainted. In doing so we put ourselves in an entirely false position with the public, who, you must remember, are, after all, to a certain extent the best judges of what they want, and you lay yourselves open to the retort I once heard a clever lady make. "Why," said she, "am I to be told that everything that does me any good is 'quackery,' and that the only thing that is not 'quackery' is taking nasty medicines, which do me *no* good?" This leads me to say a few words on the *personal* element in therapeutics, which we cannot and should not ignore. The power of adding to the influence of our remedies, the influence of personal sympathy and force of character, should be cultivated to the utmost by everyone who desires and aims at being a successful practitioner of medicine. Those who affect to despise or disregard such influences have mistaken their vocation, and although they may be men of science they are not physicians, for they have left out of their studies the most important of all subjects—the study of the human heart. You will remember, probably, the story that is told of Sydenham, who when asked by a young physician what was the most useful book for him to read, said, "Read 'Don Quixote.'" "And after that?" said the young man. "Read 'Don Quixote' again." "And after that?" "Read 'Don Quixote' a third time," was Sydenham's answer. I should like to mention to you a remarkable instance of the effect of personal influence that happened to myself. I was called, in the middle of the night, to the bedside of a gentleman who was just beginning to convalesce after an attack of typhoid fever, and his wife and his nurse, who were at his bedside, said they had sent for me because he found it impossible to sleep, and he was becoming irritable and distressed at his restless condition. I felt his pulse, and in a somewhat oracular tone directed the nurse to give him a tablespoonful of brandy with one of water; within two minutes, while we were standing by his bedside, his wife amazed me by whispering, "Look, he is asleep!" and he was, indeed, fast asleep! The next morning he greeted me with the words, "You must be a magician." He was amazed himself at what had happened.

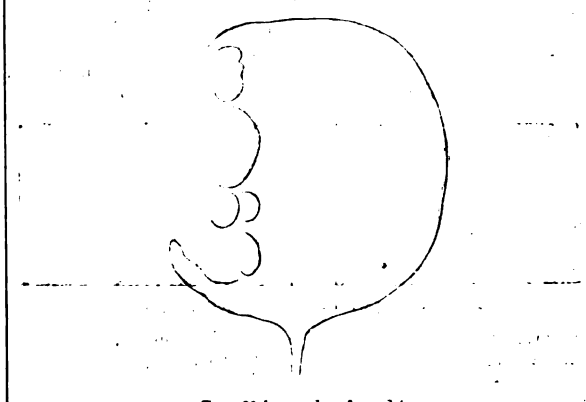
For the successful study and profitable pursuit of clinical therapeutics there are three mental qualities which are essentially necessary; they are: (1) absolute openness of mind; (2) what is almost the same thing, absolute freedom from prejudice; and (3) insight. Probably no physician ever reached great eminence in his art without the latter; it is the most precious of all gifts, and one which we should early attempt to cultivate. It is the power of penetrating through phenomena and divining their causes and meaning; the power of at once distinguishing the real from the unreal, the semblance from the reality; the power of distinguishing deceptions of all kinds, conscious or unconscious. I found a short time ago in one of my note-books the following story, the source of which I have, however, forgotten:—"An old Scotch minister was awakened out of his sleep to go to see a great lady in the neighbourhood, who was thought to be dying, whose mind was in dreadful despair, and who wished to see him immediately. The old man, rubbing his eyes and pushing up his night-cap, said, 'And when were her leddyship's bowels opened?' and on finding, after some inquiry, that they were greatly in arrears, he said, 'I thocht sae. Rax me ower that pill-box on the chimney-piece, and gie my compliments to Leddy Margaret, and tell her to tak those twa pills, and I'll be ower by-and-by mysel.' They did as he bade them—they did their duty and the pills did theirs, and 'her leddyship' was relieved." This, gentlemen, was insight; this was clinical therapeutics.

In conclusion, the point I wish to insist upon is this: The clinical method in therapeutics is, from the very nature of the investigations concerned, of necessity the ultimate and final appeal in all therapeutic questions. Whoever cares to think out this subject will see that this proposition is self-evident. To the clinical method all other methods are subservient and tributary. To extol the physiological or pharmacological method of investigation and to speak slightingly of the clinical method is to forget or to overlook the foremost and essential element in every therapeutic problem. The clinical method may be complex, difficult, and in a sense evasive and disappointing. That we cannot help; it is in the nature of therapeutic inquiries that they should be so. But I have instanced many most valuable and encouraging results obtained by this method; and I would ask most seriously and pointedly the following question: When have we, as a profession, seriously, and with something like a definite organisation, attempted to *methodise* the clinical method of investigation in therapeutics. With the establishment of the collective investigation movement in connexion with the British Medical Association the organisation and machinery needed for this purpose would seem to be at last afforded us; but the fascination of the pharmacological method is so great for some minds that it is at present difficult to obtain a hearing for the method which is far more within their means of operation, far more appropriate to the practical ends this movement seeks to accomplish, and far more likely to be productive of immediate and lasting gain to the practice of the healing art. And to you personally I would say, in necessary connexion with this subject, that it is your duty to focus, as it were, all your acquired knowledge upon one object, to concentrate all your acquirements to one end. It should never be your chief object to be a great physiologist or anatomist; or to be well versed in morbid anatomy and histology; or to be brilliant as a manipulator of surgical instruments; or to possess great diagnostic skill. I repeat, neither of these things should be your chief object, nor followed as an end in itself; but if you intend to be *medical* men, you must regard all these as but means to one chief end, and that is "healing the sick." In the zeal and ardour for the attainment of what is called a "scientific reputation" this cardinal truth is occasionally lost sight of, and I rejoiced to see that so wise and so philosophic an observer and thinker as Mr. J. Hutchinson, in his remarkable address on the "Uses of Knowledge," thought it necessary to say: "First, unquestionably, and as a thing which admits of no excuse for its neglect, you are to acquire a matter-of-fact familiarity with the common diseases and accidents to which the human frame is liable, *and their means of remedy*. Your first duty is to advise people for the best when they are ill,

Digitized by Google

and from this duty there must be no shrinking whatever." In the multiplicity of subjects which the student of medicine has to study, there is a real danger that his attention may be turned aside and his likings fixed too exclusively on one or other of the scientific subjects of collateral interest and of minor importance so far as his life-long calling is concerned; and there is, at least, an imagined superior dignity about purely scientific acquirements, acquirements that do not directly bear on the vulgar needs of suffering humanity which we must not allow to seduce us from our *real* calling. I invite you, then, to come voluntarily and examine with me the means of alleviation and cure which we possess in the treatment of those diseases which fall under the care of the physician. I do not propose to make any great demand upon your time; an hour once a fortnight through the winter and summer sessions is all, at present, I ask from you, because I wish to enter upon this subject with ample time for deliberation, selection, and preparation. I do not intend to run over hastily each year the whole range of practical therapeutics: that is what it will be my particular care to avoid. It is not my business, in any special way, to prepare you for examining boards, but to help you to prepare for the actual work of your lives. I propose, year by year, to take the treatment of some special maladies, or groups of maladies, and to endeavour to handle each subject fully and completely; and I shall, from time to time, turn aside to examine and discuss special modes of treatment, or the action and uses of special remedies. No one can, I imagine, pretend to doubt that there is a great need that a work of this kind should be undertaken, for your and my life-long work is the treatment of disease and the healing of the sick. Let us bring to that work all the acquirements that the truly marvellous progress of experimental physiology has furnished to us; all the intimate knowledge of disease which recent pathological investigations have disclosed; all the skill in the recognition and diagnosis of morbid states which our new and improved methods of physical examination supply; all the coolness and insight of the well-trained and well-equipped mind; and last, but by no means least, that sympathy with the human soul under suffering which, although it may lack "scientific precision," is dearest of all things to the human heart, upon which it falls like the "gentle rain from Heaven," and soothes, refreshes, strengthens, and heals.

THE AFTER-HISTORY OF A SUCCESSFUL CASE OF OPERATION FOR REMOVING A VESICAL TUMOUR.



BY SIR HENRY THOMPSON, F.R.C.S.,
SURGEON EXTRAORDINARY TO HIS MAJESTY THE KING OF THE BELGIANS, LATE PROFESSOR OF SURGERY AND PATHOLOGY TO THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, CONSULTING SURGEON TO UNIVERSITY COLLEGE HOSPITAL, EMERITUS PROFESSOR OF CLINICAL SURGERY, ETC.

IT is not always easy to trace the history of cases after operation, especially when successful, and to have the anatomical result verified by unquestionable evidence. I have just been favoured by Mr. J. L. Crisp, of South Shields, with the following account of a case of vesical tumour operated on by me, being Case 20 in my work on Tumours of the Bladder.

It is there recorded that, on May 30th, 1884, R. S. R——, aged sixty-three, had a firm multilobular tumour (examined by Dr. H. Gibbes) removed by me "almost level with the walls of the bladder" (*vide* sketch in the work named on page 111, and reproduced here by way of illustration), in the presence of Dr. Shippen, of New York, and Dr. Charamis, from Paris, by the perineal opening of the urethra. He made a slow recovery.

R. S. R——, wrote to me thirteen months after—viz., June 13th, 1885—"I have not the slightest sign of any return of the bleeding, have got over all effects, and am in as good health as ever I was in my life."

Mr. Crisp now informs me that owing to a bad suppurating bursa over the elbow, and severe cellulitis, the patient's arm was amputated a few weeks ago, and that he died. Mr. Crisp removed the bladder and kidneys and sent them to me, writing "that there was not the slightest sign of any return of the growth, and, in the fresh state, the cicatrix was very distinct." He adds that lately "R. S. R. occasionally passed a little blood; the specific gravity of the urine was

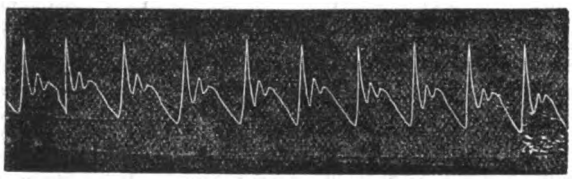
Case 20 in work referred to.

low, with traces of albumen: I suppose to be accounted for by the cirrhotic condition of both kidneys."

This is the first post-mortem examination which has come before me of a successful case, and it appears to be sufficiently interesting to be placed on record. The other successful cases are living and enjoying good health.

Wimpole-street.

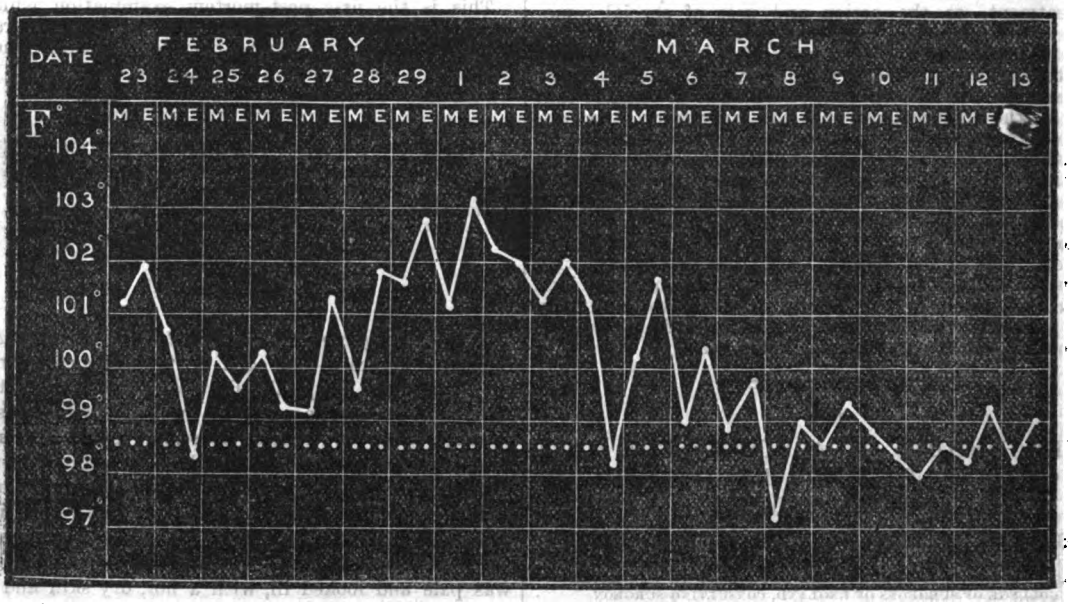
ACUTE PARENCHYMATOUS MYOCARDITIS.



BY SAMUEL WEST, M.D., F.R.C.P.,
PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK, AND TO THE ROYAL FREE HOSPITAL; MEDICAL TUTOR AND MEDICAL REGISTRAR TO ST. BARTHOLOMEW'S HOSPITAL.

(*Concluded from p. 243.*)

CASE 7. *Myocarditis associated with valvular lesions: recovery.*—James M——, aged thirty, was an in-patient in the Royal Free Hospital. He was attacked on Feb. 15th, 1884, with rheumatic pains in the hands, which lasted till the 21st, when they became worse, and pain commenced in the præcordial region. He had had three previous attacks of rheumatic fever: the first at the age of twenty-one; the second at twenty-four, and the third at twenty-six (four years ago). Since the first attack he had suffered from palpitation, and since the second with dyspnœa. The patient was pale and looked ill, with a hot, dry skin and coated tongue; the fauces were red and congested. Temperature 101·4°; respiration 40; pulse 120, bounding. There was strong visible pulsation in the carotids; cardiac dulness much increased; apex-beat one inch outside the nipple in the fifth space; impulse diffuse, and to be felt and seen as far as an inch inside the nipple in both the fourth and fifth spaces. The area of dulness extended from the apex to the middle of the third space and to the right of the sternum. A blowing systolic murmur was audible over the whole præcordial region, and there was doubtful friction near the base. Both wrists were red, swollen, and painful. There was a trace of albumen in the urine, and the bowels were constipated. A purge was administered, and twenty grains of salicylate of soda every two hours prescribed.—24th: Temperature, morning, 101·6°; evening, 98·2°.—25th: Temperature, morning, 100·2°; evening, 99·8°. Pulse 120; respiration 28. Pain less; perspiration profuse; pulse tremulous and feeble. Cardiac dulness somewhat further increased; sounds tumbling in character and indistinct; no distinct friction, but the systolic murmur was audible at the apex.—26th: Delirium last night, with horrors. Temperature 100·2°; pulse 116. Salicylate stopped.—27th: Wandering continues. Temperature varies between 99° and 101·2° during the day; pulse 108. Patient looks very ill.—28th: Wandering continues; cardiac dulness increased still further, and now reaches the second rib. A distinct friction-rub is now audible at the base of the heart, and a diastolic murmur along the sternum, but very faintly at the apex; the first



Digitized by Google

sound is reduplicated at the apex. Pulse 112, very weak; face very livid; temperature 104·4°. The albumen has been completely absent from the urine since the 26th. Fifteen minims of tincture of digitalis with ten grains of tartrate of iron were prescribed. — 29th: Pulse 128, collapsing; respiration 40. Heart as yesterday, and reduplication of apex. First sound still marked. The lividity is less, and also the wandering. The patient on the whole is better, but extremely feeble. (See Chart.) — March 1st: Patient

Pulse tracing with Dudgeon's sphygmograph.

improving. Temperature 101·6°; respiration 40; pulse 124. Cardiac signs the same.—3rd: During the night the patient became very feeble and his breathing bad, but he rallied with the administration of brandy and ether. Temperature between 103·2° and 101·4°. Blister on præcordium. — 4th: Morning temperature 100·2°, evening 101·6°; pulse 116; respiration 32. — 5th: The patient was very restless and delirious, and was constantly trying to get out of bed. A quarter of a grain of morphia was administered subcutaneously, and a second dose an hour later, after which the patient slept for a few hours. Friction-rub more marked. 6th: Six leeches ordered to præcordium, and ten minims of tincture of opium three times a day. Morning temperature 99·8°; evening, 98·6°.—7th: Patient much better, but complains of slight joint pains in shoulder and elbow. Pulse 96, stronger; respiration 24. Has had from six to eight ounces of brandy in the twenty-four hours for the last few days.—8th: The patient is still better, but extremely feeble. The cardiac dulness now extends above the second rib. The diastolic murmur is distinct, and friction still audible. Morning temperature, 99·8°; evening, 98·2°.—9th: Morning temperature, 98·4°; evening, 98·8°.—10th: Morning temperature, 98·6°; evening, 98·2°. The patient is improving, heart cardiac dulness less. Brandy reduced to four ounces. Maximum cardiac impulse in fourth space just below the nipple. From this time the temperature remained normal except on one occasion, when it rose to 101°, probably due to constipation. The patient grew rapidly improved. On March 17th the cardiac dulness had receded greatly, and now did not rise above the middle of the third space, nor extend beyond the nipple. The systolic murmur was loud and audible in the axilla, and the diastolic murmur heard over the whole præcordium, but most distinctly at the fourth left costal cartilage.—April 2nd: The patient was up for half an hour last night, but to-day the systolic murmur is louder, and it was thought wise to keep him longer in bed.—7th: The patient was up again for an hour, and the heart was beating more forcibly.—9th: Heart quieter. From this date there was rapid and uninterrupted improvement, and the patient was discharged on May 16th, feeling strong and well. The murmurs were still audible, but the diastolic had much diminished in loudness. (See Chart below.)

In the next case, the last of the series, the myocarditis was associated with extensive valvular changes. Both were acute, and the myocarditis more extreme than in any of the previous cases.

CASE 8.—*Rheumatic fever; endocarditis and myocarditis; death; extreme fatty degeneration.*—A lad aged sixteen was admitted into the Chest Hospital, Victoria-park, on April 23rd, 1881. He had been in good health until March 1st, when he was seized with rheumatic fever, and confined to bed for a week. This was his first attack. After this he was an out-patient at the hospital, complaining of præcordial pain, palpitation, and dyspnœa, and, becoming gradually worse, was admitted. He was then extremely anæmic, somewhat dusky, and suffered much from dyspnœa and vomiting, the latter having been very frequent for the last three days. The heart's action was rapid and irregular, the impulse diffused, the dulness increased, the apex being in the left nipple-line, the right border one inch beyond the middle line of the sternum; the upper border was displaced upwards, but could not be accurately marked out. At the apex was a well-marked presystolic thrill; a loud double murmur, thought to be a friction-rub, was audible over the whole præcordium. At the apex were two murmurs, one a low-pitched presystolic, the other higher pitched, rough, and systolic, and heard as well at the angle of the scapula. The liver was two inches below the ribs in the nipple-line, and there was slight œdema of the feet. On April 28th and 29th the patient was sick, and had much epigastric pain. On the 30th he became a little jaundiced. On May 1st the jaundice was deeper, and he brought up a little bright blood. On the 2nd he brought up some more bright blood, and was sick several times; the jaundice became deeper, the legs more œdematous, and in the evening the patient died.

The following is the record of the post-mortem examination:—Slight anasarca; slight jaundice; serous fluid in both pleural cavities (a pint and a half in right and half a pint in left). Slight old consolidation in apex of right lung, the lower lobe being œdematous. Liver and spleen and kidneys congested, but not otherwise abnormal. Heart weighed fourteen ounces; great dilatation of all the cavities, especially of the ventricles. No trace of pericarditis. The tricuspid orifice admitted four fingers easily; the mitral still more dilated. Aortic valves all slightly thickened, with small recent vegetation along semilunar lines, the valve most affected being that behind which there is no coronary artery.

Digitized by Google

The mitral valve is in the same condition; the chordæ tendineæ much thickened; several had ruptured, all of them belonging to the septal cusp of the valve, which was most affected. From one of the chordæ tendineæ a fragment nearly an inch long seemed to have disappeared. In the left auricle the endocardium near the appendix showed some recent thickening. The whole muscular substance of the heart was in a condition of extreme fatty degeneration; the speckling was visible both on the exterior and the interior, and on both sides. On section the fat oozed out from the surface and ran off in fine drops. The change seemed most marked in the pericardial half of the section. Under the microscope the usual appearances of advanced fatty degeneration were found. The coronary arteries were healthy.

Although the clinical record of this case is not so complete and full as it should be, it still, in connexion with the necropsy, presents many features of interest. 1. The extreme change in the heart. 2. The history which traces back the illness to the first attack of rheumatic fever. 3. The clinical condition of the patient. 4. The jaundice and epigastric pain. 5. The sickness and hæmatemesis.

The present series of cases stands as follows:—1. A case diagnosed as one of myocarditis, the necropsy demonstrating the presence of that lesion, and that only in the heart; the only other organ in the body found diseased being the liver. 2. A similar case quoted from a paper by Professor Leyden, with these minor differences—first, that in addition to recent change in the myocardium there was also evidence of antecedent disease in the presence of small fibroid patches only visible on microscopical examination; and, secondly, that the liver, which was also cirrhotic, was small instead of large, as in the first case. 3. A case of a first attack of rheumatic fever with sudden death, in which the only lesion in the heart was an acute fatty change of the muscular tissue. 4. A case similar in clinical respects, which was also fatal, but in which no post-mortem examination could be obtained. 5. A case also occurring in a first attack of rheumatic fever, which recovered completely. 6. A case in which, after a desperate struggle, recovery also took place, but a faint systolic murmur persisted. 7. A case of old morbus cordis, in which, after a similar clinical history, recovery occurred, but the evidence of the old lesions of course remained. 8. Lastly, a case of a first attack of rheumatic fever in which similar symptoms gradually developed and ended in death, and the post-mortem disclosed, in addition to acute valvular disease, the most extreme muscular degeneration of the series.

The resemblance between all these cases is too striking to be mistaken, and justifies the reference of them all to the same family group, for which I prefer to retain the usual name of "acute myocarditis." An analysis of them presents us with the following facts:—

Sex.—All the cases occurred in males, except the third. This is remarkable, for the liability to rheumatic fever is about equal in the two sexes, and it seems to indicate that there is no necessary connexion with this disease.

Age.—Male, aged fifteen (Case 5); male, sixteen (Case 8); female, twenty-four (Case 3); male, twenty-seven (Case 1); male, thirty (Case 7); male, thirty-four (Case 2); male, thirty-six (Case 4); male, forty-four (Case 6). All the cases occurred therefore before the middle period of life, and some at quite an early adult age. This serves to mark off distinctly the acute affection of the heart described in them from the gradual failure of the heart due to fatty change in old people—i.e., from the common form of so-called fatty heart.

Cause.—In four cases the attack could be distinctly attributed to rheumatic fever; in three of these there had never been a previous attack, and two of them died. In the fourth there had been three previous attacks, which had left extensive valvular mischief behind. In another case the patient had suffered previously from rheumatism, but not at all during the present illness. In a sixth case there was a doubtful history of rheumatism. In the two remaining, a rheumatic history was absent. Both were heavy drinkers and had been in want recently, and one of them had suffered not long before from syphilis. Both of these died.

Mortality.—This is high. Out of the eight cases recorded here, five died, three quite suddenly. In two cases recovery was, so far as could be judged, complete.

These facts would seem to prove what is commonly stated that myocarditis generally occurs in the course of rheumatic fever, but pains in the limbs are noted in many of the recorded cases, and in some the ordinary signs of rheumatic affection of the joints are distinctly stated to have been absent, so that the mere occurrence of indefinite aches and pains in the limbs is not conclusive proof that the case is one of rheumatic fever; and both Kühle and Köster describe these pains as part of the disease, and as not being necessarily those of rheumatic fever.

Clinical symptoms.—All the patients excepting one, were desperately ill. In this one exception (Case 3) there seemed to be nothing in the patient's condition to cause alarm, until she suddenly turned faint, fell back, and died. The prominent symptoms in all were duskiness, panting dyspnœa, with extreme feebleness of the heart and pulse. The temperature was raised in nearly all. In Case 7 the temperature chart was mislaid, and in Case 8 the temperature was normal. In the others it varied much, but never reached a great height, averaging about 101° or 102°, and that for no prolonged period. As there was a rise in temperature in one of the non-rheumatic cases, the explanation must be looked for, not in the rheumatism, but in some other cause, and we may compare with it the rise which is not uncommon in valvular disease of the heart, especially in cases of aortic regurgitation. Although no anatomical explanation of this is forthcoming—i.e., no inflammation or infarcts are found in many cases,—its grave import is well known, and it may turn out that we shall be justified in referring the rise of temperature to the condition of the heart itself. The rate of respiration was rapid in all the cases. In four there was distinct evidence, in the presence of bronchitic sounds, of congestion of the lungs; but in the other four the cause of the dyspnœa and cyanosis must be looked for elsewhere. The dyspnœa was not of the laboured obstructive kind common in bronchitis, but of that panting character which has sometimes been plainly called cardiac dyspnœa. Jaundice was present to a slight extent in three cases; in two of these there proved to be gross disease of the liver (viz., cirrhosis), but in the third the jaundice was probably due to congestion, for in this, as also in two others in which jaundice was absent, the liver was enlarged at first and gradually diminished in size as the patient's condition improved. Œdema of the feet was absent in four cases and present in four, though to a slight extent only, and without any ascites in three cases and with ascites in the fourth. The urine was usually diminished in quantity. In five cases it contained albumen in slight amounts, varying from day to day and disappearing with recovery. In the other three albuminuria did not occur. There was no relation between the albuminuria and œdema, the former being present sometimes when the latter was absent, and *vice versâ*. Delirium of a low, wandering kind occurred in six out of the eight cases, and appears to be one of the most constant phænomena. The delirium was associated with drowsiness and heaviness in four out of these six cases, and in three of them uræmic-like twitchings of the limbs and body occurred. In Case 1 these twitchings almost amounted in severity to fits, but although in that case there was a slight amount of albumen in the urine, the twitchings occurred in other cases where it was absent, and hence they cannot be attributed rightly to uræmia. They are probably evidence of asphyxia. The first case suffered greatly from attacks of faintness, with cold sweating; but though the faintness occurred in other cases, the cold sweats did not. The pulse was in all cases extremely feeble, fluctuating greatly in force and frequency; the tension in the vessels was low, and the pulse wave small and ill-sustained. The rate in most cases was rapid, the slightest effort or excitement sending the rate up many beats in the minute. The extraordinary effect which digitalis had in reducing the pulse-rate observed in Case 6 was also observed and commented on by Prof. Leyden in his case (Case 2). Præcordial pain was a prominent complaint in five cases, and palpitation was frequent. It was to the heart, as the source of all trouble, that the symptoms seemed to point, and it was in this organ that most clinical evidence of disease was found. The cardiac dulness was increased in seven out of the eight cases. In this one the obesity of the patient prevented the cardiac area being determined accurately. The apex was displaced to the left. The increase of dulness was chiefly to the left and upwards, indicating dilatation of the left side of the heart. In Case 6 the diagrams show an increase also to the right, and the dilatation was therefore general and very considerable. As the patient recovered, the area of cardiac dulness contracted in all directions, and at last did not extend towards the right beyond the left edge of the sternum,

Digitized by Google

though it was then somewhat increased towards the left. The sounds were extremely feeble in all the cases. This enfeeblement affected especially the first sound, which in one case could hardly be heard at all. There was no murmur or friction audible at any time in four cases. In another a soft-blowing systolic murmur was audible for a time over the whole præcordial region and subsequently disappeared. In one other a faint systolic murmur at the apex was audible throughout and persisted after recovery. This was in an old rheumatic case. In the remaining two there were the permanent murmurs characteristic of gross valvular disease. The clinical symptoms seemed all to point to the heart as the organ in fault, and in those cases in which death took place and a post-mortem examination was made, it was in the heart that the chief, or in some cases the only, lesion was found; and in three out of the five fatal cases the pathological change was confined to the myocardium, so that the history of the disease is complete.

The present series of cases appeared to me worthy of being put on record together for these reasons: (1) that, although the difficulties are great, the diagnosis of myocarditis can often be quite correctly made; and (2) that myocarditis is, as I believe, not by any means so rare an affection as is commonly stated.

Wimpole-street, W.

FIVE ADDITIONAL CASES OF CHOLECYSTOTOMY.

BY LAWSON TAIT, F.R.C.S.

THE following five cases complete a series of twenty-one cases of cholecystotomy, in all of which recovery has taken place.

CASE 17.—This patient is a male, practising as a physician in London, and aged forty-eight. His first trouble, in February, 1882, was a severe attack of colic occurring after dinner, and lasting some hours. During the spring of that year he had several similar attacks, always commencing about midnight, when asleep in bed. He was free for some months until August, when after a day's hunting an attack commenced about six o'clock in the evening, followed by obstinate vomiting, which left the patient very prostrate. The winter of 1883 he passed in the Riviera, and was free from any attacks. He returned to London in the middle of May and resumed his work, and very soon had a similar attack, quite as severe as any of the former. This was followed by repetitions at about a fortnight's interval, in many of which death appeared imminent; and an endless number of therapeutics were resorted to in vain, relief being obtained only from hypodermic injections of morphia. All who were consulted regarded it as a case of gall-stones, but the patient himself did not concur in this view. The attacks were sometimes, but not always, followed by jaundice, and occasionally an ill-defined tumour in the region of the gall-bladder could be discovered. In his own words, throughout the illness the most obviously exciting cause of the attacks was posture, stooping over a writing-desk; and he ultimately had to do such work either kneeling or at a standing desk, and in lying he had to be on his right side whenever possible. Active physical exercise, such as tricycling, fishing, and hill-climbing, seemed to have considerable effect in warding off the attacks. I saw him on October 2nd, and found that during two years he had gone off from being a man of nearly fifteen stone to very little more than ten. He had a distinctly jaundiced appearance, and on examination I believed I could feel the gall-bladder distended. The palpation under this necessary examination brought on a severe attack of pain, and with it something almost of the nature of a convulsion. His temperature went up to 104°, and the pain was so severe that chloroform had to be administered. It was thought by all of us advisable that cholecystotomy should be performed next morning, and, in the profound belief that I should find a calculus obstructing the cystic duct in a valve-like fashion, I performed the operation next day, but found no stone. I established a biliary fistula, and the patient made a very easy recovery. His temperature never exceeded 37° C., and the highest pulse record was 79. There has been no attack of pain or distress of any kind since, and the patient is rapidly regaining health and strength. We have sent him away on a six months' voyage, with the fistula still open, and with instructions to let it close if it likes, but on the recurrence of any symptoms to have it reopened.

CASE 18.—R. J——, aged forty-eight, resident in Birmingham, was placed under my care by Dr. Rogers, with a well-defined tumour in the region of the gall-bladder, extremely tender on pressure, and with a history of several years' suffering from severe gall-stone colic—her life, in her own words, having been miserable for years on account of incessant discomfort and pain. I found the gall-bladder distended with about two-thirds of a pint of pus, and the neck blocked up by a large solitary calculus firmly impacted in it. I had to break it up to remove it. A few hours after the operation bile flowed freely through the wound, and the patient made an easy and uninterrupted recovery. The fistula has now healed, and the patient is perfectly well.

CASE 19.—E. S——, aged thirty-two, resident in Birmingham, was sent to me by Dr. Hoare with all the symptoms of gall-stones, but I could not discover any indication of distension of the gall-bladder. I therefore diagnosed it as a case of multiple small gall-stones. I operated upon her on November 11th, and found my view correct. I removed eight small stones; but, as her sufferings had existed for many years, the probabilities are that she had passed the great majority of the calculi with which she was troubled. The attacks came on at intervals of two or three months, and lasted for two or three weeks; so that if I had left her alone, nature would probably have cured her in about two or three years; but as we had no guarantee of that, and as the patient was completely exhausted by suffering and desirous of obtaining relief, the operation was performed, and, I think, even for the sake of shortening her sufferings by two or three years, was completely to be justified—at least, that is her opinion.

CASE 20.—M. B——, aged fifty-seven, placed under my care by Drs. Quirke and Wade. The lady had passed a large number of gall-stones, having had severe attacks at short intervals for several years; the gall-stones were all of moderately small size. I opened the gall-bladder on December 12th, 1885, and removed eighty-four stones, which varied not a very great deal in size. She made an easy recovery, and is now completely well, although the fistula is not yet healed.

CASE 21.—On December 21st, 1885, in the clinical wards of the Royal Infirmary of Edinburgh, I performed cholecystotomy on a man at the request of Professor Grainger Stewart. The symptoms were those of suppuration, not very clearly those of gall-stones. After a consultation with Professors Chiene and Annandale, and others of the staff, I opened the abdomen rather with the belief that I should meet with an abscess of the liver than what turned out to be the case—a suppurating gall-bladder full of gall-stones. The patient is still under treatment, and on the whole is progressing very well. The details of the case will be shortly published, with remarks by Professor Grainger Stewart himself.

By far the best of the recent papers upon cholecystotomy is one by Dr. Augustus C. Bernays of St. Louis, which appeared in the *Weekly Medical Review* for Oct. 31st. The title is one which is a little puzzling until the paper is read—"Ideal Cholecystotomy"; and the author discusses three possible operations for the surgical treatment of gall-stones. His "ideal cholecystotomy" is that where he can close the opening into the gall-bladder and drop the cyst back; and for the first time in his hands this operation has been successful. The second operation of which he speaks is what he calls "natural cholecystotomy"—that is to say, the operation I have performed successfully twenty-one times, imitating the process of nature by securing the adhesions of the gall-bladder to the abdominal wall, and the formation of a fistula as part of the treatment. The third operation is "cholecystectomy," which, he says, should be limited to cases of otherwise incurable or malignant disease of the gall-bladder.

One or two points in the paper are worth a little discussion. The last which I have mentioned—the limitation of cholecystectomy—I should extend further than Dr. Bernays has done; because nothing would induce me to remove a cancerous tumour of the gall-bladder, for there could be no reasonable amount of hope that the disease would not return. I cannot imagine any other kind of disease of the gall-bladder which would be incurable; for in some of my cases suppuration has led to almost complete disorganisation

Digitized by Google

of the organ, and yet after drainage for some weeks it was completely restored to its functions, whatever they may be. Dr. Bernays says that ideal cholecystotomy is indicated when the bladder is normal in structure, and when the gall-ducts have been cleared of obstructing calculi. But he seems to be perfectly well aware of the validity of the conclusion which I have completely established, that it is absolutely impossible to be sure that the gall-ducts have been so cleared. His own case of successful ideal cholecystotomy was an example of which I have seen a considerable number, where, by the chronic inflammatory change effected by long impaction of gall-stones, the duct was practically obliterated. In such cases the regurgitation of bile after the operation does not take place until the inflammatory effusion has subsided, many days after the operation, sometimes two or three weeks; therefore it was not really a fair chance to test the efficacy of his ideal operation; and supposing that the accident of subsequent suppuration took place, a not unlikely thing after such an operation, nothing could happen but that the suppurating gall-bladder would discharge its contents through the aperture made at the time of the operation. One other point is the consideration of the possibility of a subsequent formation of gall-stones, and is a very strong argument in my own mind against Dr. Bernays' ideal cholecystotomy; for if such a thing should happen the whole operative process must be gone over again. On the other hand, if my proposal, characterised by Dr. Bernays, and very appropriately, as natural cholecystotomy, had been carried out, a single incision into the adherent gall-bladder, guided by a tattoo mark, which can be very easily left to identify the site, would enable complete and effectual relief to be given without any risk at all. This is an argument in favour of the operation I advocate, which I have frequently pointed out, and which I desire again to put into prominence. In all other respects I entirely agree with Dr. Bernays, more particularly in his condemnation of the transcendental cholecystotomy of Dr. Gaston.

Birmingham.

STUNNING AND BURN BY AN ELECTRIC LAMP.[1]

BY GEORGE BUCHANAN,
PROFESSOR OF CLINICAL SURGERY, GLASGOW UNIVERSITY.

INJURIES from electric lamps are becoming not infrequent. In most of the cases related death has been instantaneous. In a case reported on Jan. 22nd as occurring at Liverpool the man was stunned and remained unconscious for a time and on recovering was found to be quite blind. The case here related is very curious as to its causation and its effects.

William C——, aged forty-four, a workman in Clydebank building-yard, was engaged at a crane on Nov. 19th, 1885, At the extremity of the wooden arm of the crane was an iron pulley, over which hung an endless chain for raising weights. The man had occasion to pull at the chain, and while so doing an electric lamp, which was suspended above, by some mischance was lowered till it touched the iron pulley. The lamp was one of the arc kind, worked on the brush system. The instant this occurred the man felt a shock pass through him, became "doubled up," and then lost consciousness; but he did not fall to the ground, being held up by the chain which his hands firmly and involuntarily grasped. Some three or four minutes elapsed before the electric current was cut off at the machine, when the man dropped down on the ground stunned. He was taken to the Western Infirmary about an hour afterwards, by which time he had recovered consciousness and could give a distinct account of what had happened. The injuries received were not very severe. There was a vesication on the palm of his hand where it held the chain; also one on the side of his neck, which rested against the chain during his pulling it down. On the sole of his right foot in front, where the chief weight of his body rested in the act of pulling, was a spot about two inches square, where the tissues were completely charred by the heat of the current passing into the ground. There were no nails in the boots, and there was no perceptible evidence of heat on them, but the sole of the stocking was charred opposite the charred part of the foot. Sir William Thomson, who questioned the man after his recovery, explains that the moist foot of the stocking must have acted as the medium of conduction between the man's body and the ground, and so determined the seat of the burn.

The symptoms complained of were not very severe; they consisted of a slight amount of general shock, a feeling of heat in the abdomen and chest, and dimness of vision, all of which passed off in twenty-four hours. The wounds were treated in the ordinary way. A large slough separated from the sole of the foot, followed by rapid granulation and cicatrisation, and the man was dismissed cured in about six weeks.

Sir Wm. Thomson suggests that if any of the bystanders had taken the man by the clothes and drawn his feet from contact with the ground, or had thrust a bit of dry clothing of any kind under his feet, the contact would have been broken, and the hand relieved from its grasp of the chain. The wonder is that an electric current powerful enough to char the thick integument of the sole of the foot, passing through the man, did not produce any internal mischief.

[1] From notes by John Macdonald, M.B.

LARGE FIBROID TUMOUR OF THE UTERUS.

SPONTANEOUS EXPULSION; CURE.

BY W. H. JALLAND, F.R.C.S.,
SURGEON TO THE YORK COUNTY HOSPITAL.

ALTHOUGH spontaneous expulsion is one of Nature's ways of performing a cure in this condition, still, as it of so comparatively rare occurrence for large fibroids to be got rid of in this way, I think this case worthy of record. I first saw the case in consultation with Mr. Aylward, of York, on Jan. 2nd, 1885, on account of severe hæmorrhage from which the patient was suffering, and which at one time looked as if it might prove fatal. When I first saw her she was in such a feeble and blanched state that very little examination could be made, all our energies being directed to stopping the bleeding. This was fortunately done with the aid of ergot, ice, and opium, together with absolute quiet. I may say the bleeding had almost stopped before I saw her, through the active measures Mr. Aylward had adopted. I saw the patient again with this gentleman on Feb. 7th; the bleeding had then almost ceased, but she was apparently getting into a septicæmic condition, with a temperature of about 102°, tenderness over the abdomen, fetid discharge, and brown tongue. Thinking I should have her more under control in case the hæmorrhage returned, I advised her removal into the York County Hospital, which was accordingly done on Feb. 12th; and the following notes were taken during her stay there by Mr. T. Birt, junior house-surgeon.

Mrs. B——, aged forty-one, married. One sister died from recurrent tumour of arm; other relations healthy. Previous history good. Had three children; one died in infancy. No miscarriages. Two years ago (five or six years after the birth of the last child) she noticed a small lump in the lower part of the abdomen, which never gave her much inconvenience, but gradually increased in size till last Christmas, when she was seized with an attack of severe flooding, and since then has been subject at intervals to similar though slighter attacks. On admission, the patient was emaciated and very blanched, the mucous membrane of the lips being white. She complained of pain in the lower part of the abdomen, which kept her awake at night. She said she had a discharge of blood, which was not so profuse as it was a week ago. The vaginal discharge was very fetid, being noticeable for some distance from her bed. There was present an enlargement, dull on percussion, roundish in outline, and smooth, passing upwards out by the pubes to a point about three fingers' breadth above the umbilicus, and occupying the median line; from the tumour there bulged outwards at its upper part towards the right hypochondrium a smooth swelling about the size of an orange, giving a semi-fluctuating sensation on palpation. The whole mass could be moved slightly from side to side. On examination per vaginam the os was patulous and open, readily admitting the finger; discharge purulent and fetid. The sound passed readily into the cavity of the uterus for 6½ in. Temperature 101·2° at 8 P.M. She was ordered a

Digitized by Google

mixture of cinchona and ammonia, an ounce to be taken three times a day; carbolic acid lotion (1 to 60) to be used as an injection every four hours. To have a diet of mutton, strong beef-tea, and milk, and half a point of porter daily.

Feb. 14th: Patient much the same. Discharge very profuse. Complains of much pain. Ordered half a grain of opium pill three times a day. Only one slight occasional hæmorrhage. Temperature ranges between 99·2° and 101·8°.—19th: Same condition. Mixed with the discharge have been a few waluut-sized irregular masses of white fibrinous-looking material (she passed one or two of these before her admission). One of these was examined under the microscope and was found to be identical in appearance to the fibroid tumour, only that no bloodvessels could be detected in it. As she complained of feeling sick, she was ordered a mixture containing bismuth and soda.—23rd: Sickness gone. Still passes flocculent masses about every other day. Size and external outline of uterus remain about the same; discharge still very fetid. Ordered half a drachm of iodoform and glycerine to be used with the injection. Temperature on two mornings below 99°, at night between 100° and 102°.

March 2nd: Irrigated uterus by means of uterine douche, iodoform being used in the injection; douche used for the next two days.—5th: The following was noted to-day: Sound only goes in for about three inches and a half; fundus uteri two fingers' breadth below umbilicus; not half so much discharge, and not so fetid.—8th: Discharge still further lessened in quantity. Ordered some ergot and nux vomica.—11th: Discharge odourless. The uterine douche, which had been used every other day, was now discontinued on account of difficulty of introduction. During the last seven days one or two fibrinous masses have been expelled. Temperature normal in the morning, and only occasionally rising at night.—25th: Got up to-day. Regaining colour. Still a slight inodorous leucorrhœa. Ordered some steel.—29th: Catamenia commenced, ushered in with characteristic and normal prodromata. This discharge was lighter than usual, and continued always very moderate in amount for five days.

April 8th.—Getting fat. Walks in the garden daily. Uterus normal. Ordered some tincture of steel and nux vomica.—12th: Went out to-day well.

July 18th.—Has been seen several times since her discharge. Has had her usual monthly periods with only an average loss. Has gained flesh, looks well, and has regained her natural colour.

A CASE OF

EMPYEMA WITH CEREBRAL ABSCESS.[1]

BY DAVID W. FINLAY, M.D., F.R.C.P.,

PHYSICIAN TO THE MIDDLESEX HOSPITAL, AND TO THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

THE subject of the following communication was a young man aged twenty, who came under my care in the Middlesex Hospital on Dec. 17th, 1884. On admission his temperature was 99·6° F.; pulse 80, of good force, and regular; respiration 24; tongue clean and moist. He was described as fairly well nourished, but rather anæmic, with clubbed finger-ends, and complained of a discharge from an opening in the left side. On examination of the chest the left side was markedly retracted, and did not move in respiration; the right front moved more freely than normal. Resonance and breath-sounds over the right front were excessive. As regards the left front, the resonance was marked as far down as the third rib and as far out as an inch and a half beyond the vertical nipple-line. Past these limits resonance was rather abruptly replaced by absolute dulness, which extended right round to the back. Over this dull area the breath-sounds and tactile fremitus were wanting, while both, together with vocal resonance, were rather exaggerated over the resonant area above the nipple. There was a small opening discharging pinkish-coloured pus in the fourth interspace of the left front in the parasternal line. The discharge was small in quantity and not offensive. Turning to the back, there was impaired resonance on the left side from the spine of the scapula downwards, and the breath-sounds were wanting, except towards the spine, where they could be faintly heard. Over the right back the breathing was harsh; there were no adventitious sounds to be heard anywhere. The heart's maximum impulse was apparent in the third interspace immediately to the right of the sternum. The first sound was accompanied by a blowing murmur in this situation, the second sound was clear and sharp. The patient had no cough and no sweating at night. The urine had a specific gravity of 1015, was faintly acid, and contained no albumen or sugar. The family history was quite satisfactory, and he had enjoyed fairly good health up to the present illness, which began in an attack of pleurisy in July, 1883, about eighteen months before his coming under observation. He had been tapped three times at weekly intervals, and after the lapse of a month his side was incised and irrigated daily. Under this treatment the discharge had gradually diminished and he was sent to the seaside as cured; but it had become more profuse again, and had continued so for a year or more, being variable in quantity but showing no tendency to dry up. It should be noted that before being incised the empyema had pointed, and the skin over it was, as he described it, "as thin as paper." There was nothing abnormal in the abdomen.

As it was quite obvious that the only chance of curing the empyema lay in establishing a free exit for the pus and endeavouring to get the side to contract, so as to abolish the abscess cavity, he was taken into the operating theatre five days after admission (Dec. 22nd), and had a free opening in the chest made, at my request, by Mr. Gould, who removed a piece of the fourth and fifth ribs at the seat of the discharging sinus. An abundant escape of rather fetid pus took place; a large drainage-tube was inserted and the usual dressings applied after the pleural cavity had been irrigated with a warm solution of permanganate of potash. This irrigation was continued daily, and he went on perfectly well for a time, the quantity of discharge gradually diminishing. He had a good appetite, slept well, and had no rise of temperature or other untoward symptom. On Dec. 30th, however, eight days after the operation, he was seized at three o'clock in the afternoon with a convulsion of an epileptiform character, which lasted with more or less severity for about fifteen minutes. The fit was repeated six times within the next twenty-four hours. I did not see him in any of the attacks, but the following was the description of them given to me by those who did. The first thing observed was clenching of the teeth and spasm of the muscles of the neck, and this was followed by rigidity of the muscles of the trunk and extremities, the legs being extended and the arms flexed. His head was turned to the right, to which side the eyes also deviated, and there was twitching of the lips and eyebrows; the face became cyanosed, and he bit his tongue. When the spasm passed off, the patient lay in an almost collapsed state, with slow stertorous breathing. During the attack the pupils were contracted, but dilated afterwards, and were inactive to the stimulus of light. The urine was passed incontinently. All the other fits were stated to be similar to the above, only lasting longer. He was very drowsy and stupid between the fits, and after they passed off he complained of headache. When these attacks finally passed away, it was noticed (Jan. 2nd) that the tongue was protruded to the left and the face drawn to the right, and that he complained of shakiness of the left arm, in which there was considerable loss of power, the grasp of the left hand being also very feeble. Otherwise, on this day he was improved; the pupils were equal and active; he had slept well, and taken his food well; there was very little discharge from the wound, which looked healthy. He was brighter as to his mental condition. On ophthalmoscopic examination the optic discs appeared quite normal. I should have stated that the irrigation of the pleura had been discontinued on the first appearance of the convulsive attacks.

I need not take up time by tracing his condition from day to day. It will be sufficient to say that the face remained paralysed, the paralysis of the arm increased (particularly as regards the muscles of the forearm), and was followed in four days by progressively deepening paralysis of the left leg. With all this the pulse was slow, about 60; frontal headache was complained of, and the temperature was rather subnormal. On January 9th he had an attack of vomiting, and he was noted to be becoming duller in intelligence: he could not be made to understand or answer questions. On this day also another ophthalmoscopic

[1] Read at the meeting of the Medical Society of London, Feb. 8th.

Digitized by Google

examination was made, but nothing abnormal discovered. From this point onwards his stupor gradually deepened; he had a slight return of the vomiting, became profoundly comatose, and died quietly on January 13th, at 12.45 A.M.

The necropsy was made by Dr. Fowler, sixteen hours after death, and the following was the condition of things:—There was the opening of a sinus in the fourth left interspace in the mammary line, admitting the little finger, and leading to the sac of an empyema, which

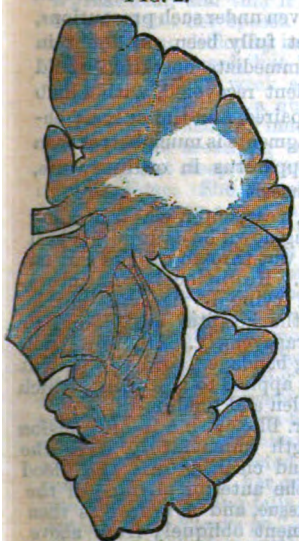


FIG. 1.

Lateral view, showing seat of abscess.

occupied the lateral and posterior aspects of the left side of the chest. The side was much contracted, the lower intercostal spaces being almost obliterated by the coming together of the ribs. The pleural layers were converted into dense fibrous walls nearly half an inch thick, enclosing a space about seven inches and a half in vertical measurement, lined by a soft and highly vascular membrane. This contained scarcely any pus, but on pressure of the chest-wall above the external opening, about half an ounce of pus oozed out. This was found to come from an abscess sac situated over the third interspace. As for the lung itself, both lobes were collapsed posteriorly, but the anterior part of the upper lobe was crepitant. The right lung was crepitant throughout, but presented some adhesions posteriorly, and slight œdema of the base. The heart was found displaced to the right; the pericardium was normal; the heart's valves were also normal in appearance and competent; the muscular substance was rather soft. There was nothing noteworthy found in the abdomen. The right side of the brain on removal of the membranes was seen to be much enlarged, bulging towards the left, with much flattening of the convolutions of the surface. (Fig. 1.) There was no meningitis. After being hardened in spirit, the brain was divided by vertical sections, one of which is shown in diagrammatic form in Fig. 2. The abscess was found to begin at the middle of the anterior border of the ascending frontal convolution immediately beneath the grey matter, extending backwards in the centrum ovale underneath the fissure of Rolando into, but not beyond, the ascending parietal convolution. It was nearest to the surface just in front of the fissure of Rolando, where it encroaches upon the grey matter. The abscess cavity was widest from side to side immediately beneath that fissure, where in the hardened brain it measures two inches, extending inwards to a point just above the lateral ventricle, and about a quarter of an inch from the caudate nucleus. The whole brain measured seven inches and a quarter in length, the length of the abscess being three inches. The abscess had no limiting wall or lining membrane, the cavity presenting a rough and ragged surface.

FIG. 2.

Vertical section from upper part of fissure of Rolando to optic commissure, showing seat of abscess.

Regarding the empyema little need be said, the chief interest of the case centring in the cerebral abscess. Nevertheless, I may briefly refer to one or two points.

Irrigation of the pleural cavity has been followed in a number of cases by attacks of an epileptiform character, and speedy death. I can recall very vividly a case of this kind, which occurred in the Middlesex Hospital ten years ago, and which is recorded by Dr. Cayley in the tenth volume of the Clinical Society's Transactions. In such cases, however, the attacks have come on when the pleura was actually being irrigated or injected, and no lesion has been found in the brain after death. In the present case the fit did not occur till about three hours after the irrigation of the pleura; and although, as a precautionary measure, I ordered the discontinuance of the irrigation, I cannot say that I look upon the relation of the two things to each other in the light of cause and effect. At the same time it is conceivable that they might have such a relation, the manipulations necessary during the irrigation possibly loosening a thrombus, which a subsequent movement or coughing on the part of the patient finally detached. And I think it is quite worth while considering whether the washing out of the pleura, except in special cases—those, for example, in which the pus is very fetid—is worth the risk run. I think that if a free exit is provided for the pus, the washing out in the general run of cases is not necessary, and may be mischievous. Towards securing this free exit, I should say that there are few cases in which the removal of a portion of rib can be advantageously dispensed with; and if this course were followed early in cases of empyema, I believe that the results generally would be more satisfactory.

As to the ultimate cure of the empyema in the present case, had the complication of cerebral abscess not cut short the patient's life, the abscess cavity in the pleura was so large, and the bony case enclosing it on one side so absolutely unyielding from the contact of the ribs and thickening of the pleura, that nothing but a very free removal of ribs, and probably not even that, would have availed to produce obliteration of the sac, for it must be remembered that but little help would have come from the collapsed lung. If, however, more than a year had not been practically lost in the effective treatment of the case, I cannot help thinking that the result might have been widely different.

So much for the empyemal side of the case. As regards the brain when the epileptiform attacks occurred, followed by left hemiplegia, it was not difficult, having regard to the empyema, to read aright the cerebral symptoms—there was little doubt that an abscess had formed in the right side of the brain. On the subject of cerebral abscess little, if anything, has been added to our knowledge since the publication of the article by Gull and Sutton in "Reynolds's System of Medicine;" and the present case is chiefly interesting in that it exemplifies one of the rarer conditions under which the disease occurs. Of seventy-six cases tabulated in the article referred to (and this appears a fair number on which to establish a rule of proportion), three only were consequent upon empyema. As to symptoms in the present case, the chief in diagnostic importance, after the convulsions and consequent hemiplegia, was pain in the head, referred mostly to the frontal region; but it was seldom very marked, giving the impression rather of a dull aching than positive pain. Vomiting was present only to a very trifling extent. There was no rigor, and the temperature was almost always subnormal, exceeding 100° F. on one occasion only. This point, the absence of pyrexia in cerebral abscess, has, I think, been noticed by several recent observers.

Regarding etiology, the abscess must be supposed to have owed its origin to some minute coagulum carrying septic infection from the suppurating focus in the chest, or from the divided rib ends. This, of course, is in general only a matter of reasonable inference; but the missing link has in one case been supplied by Boettcher, who is said to have found lung pigment in the cavity of a cerebral abscess, which followed abscess in the lung. But we do not thus

Digitized by Google

get rid of all difficulty; for to infect the brain the septic material must first have been carried to the right side of the heart, sent through the lungs, returned to the heart, and then propelled to the brain.[1] But how did it pass through the lungs without leaving pyæmic abscesses there to attest the route of its progress? We know that in ordinary cases of pyæmia the lungs are prone to be the seat of metastatic abscesses. Why should they escape in such cases as this? Is it because particles not fine enough to escape arrest in the brain are yet able to pass through without lodging in the lungs, or because cerebral tissue is in some cases more apt to take on inflammatory action? If the latter, it may be that the long-continued suppuration of the empyema may induce a more than ordinary liability to suppuration in the brain. But these are matters of speculation.

Finally, as to treatment. I need hardly say that the question of surgical interference was discussed more than once. One thing in its favour was that there was little difficulty in saying where the seat of the abscess would be found. The symptoms noted during life pointed to the neighbourhood of the fissure of Rolando. But there were other points to be taken into consideration. First, the contents of the abscess might not have been so liquid as to have been readily removed when found, resembling, perhaps, more a diffused softening than completely formed pus. Secondly, the progress and extent of the paralytic symptoms led to the belief that a large area of brain was involved, to which probably permanent damage had been done, and even if the dangers of the operation itself had been safely surmounted, the ultimate prospects were not encouraging. Notwithstanding these considerations, however, I regret that the evacuation of the abscess was not attempted, although, perhaps, the result would have been of more advantage to medicine than to the patient himself.

DRY DRESSINGS FOR INTERNAL CAVITIES.[2]

BY CHARLES F. HUTCHINSON, M.D.,
MEDICAL OFFICER TO THE ROYAL NORTHERN SEA-BATHING INFIRMARY, SCARBOROUGH.

DRY dressings being now all the fashion, and to my mind most justly so, I wish to draw the attention of the profession to a very simple method of applying, in the dry state, dressings, styptics, &c., to such cavities as the vagina, uterus, and rectum.

The only apparatus required is a hollow cacao-butter suppository, which suppositories are made in various sizes, the largest of which will just about hold one drachm of any ordinary powder. These hollow suppositories are filled with the powder that may be wished to be used as a dressing; the small lid, after being gently heated, is put on; this when cool remains fixed, and the whole apparatus is then ready to be introduced into the vagina or rectum. The heat of the body soon melts the cacao butter, and the powder is then brought, in as dry a state as possible, into direct contact with the parts. During the last six months I have used these suppositories most freely, and have been more than satisfied with the result. I have tried all sorts of powders, and as the result of my own experience strongly recommend the following, either alone or in various combinations as required.

Firstly, as a styptic I most strongly recommend powdered iron-alum. I generally order one drachm of powdered iron-alum and five grains of iodoform, to be well mixed together, the powder to be inserted into a hollow suppository and used as directed. In the treatment of uterine hæmorrhage I am convinced there is no remedy of more universal application, and none on which I could with greater confidence rely. I have used it in severe hæmorrhage from uterine fibroid, from uterine polypus, from uterine cancer, bad miscarriage, and in several cases of menorrhagia at the change of life, and it has never yet failed me. All that is required is to introduce the suppository as high as possible into the vagina, and there leave it. It is as easily applied by the nurse as by the doctor, and is in every way perfectly safe and harmless.

Secondly, as a dressing iodoform stands pre-eminent; in fact, I now seldom use anything else. This, when combined with from a quarter to half a grain of morphia, forms by far the best dressing for uterine cancer that I have yet tried.

Thirdly, morphia, either alone, or, as I generally now use it, in combination with either or both of the above, is a great aid to the physician and comfort to the patient.

After attention has once been drawn to this simple mode of applying these various applications, the numerous uses to which they might be put in the various vaginal, uterine, and rectal discharges and diseases will occur to all. I have only very briefly ventured to suggest the use of those which in my own hands I have found deserving of confidence. I have no doubt that hundreds of the profession are at present using this mode of dressing; but, on the other hand, I know that there are hundreds who are not, and it is to persuade those who have not yet tried them that I venture to bring this subject forward.

[1] There is always, of course, the alternative previously referred to and preferred by Dr. Broadbent, of thrombus by the direct route of the pulmonary vein; but this would not cover the case of the divided rib-ends.

CHARING-CROSS HOSPITAL.

TRANSVERSE FRACTURE OF THE LEFT PATELLA; OPERATION; CURE.

(Under the care of Mr. J. ASTLEY BLOXAM.)

THE question as to the best treatment in cases of fracture of the patella is one which still occupies the attention of practical surgeons: whether to treat the fracture by means of splints, strapping, Malgaigne's hooks, or other apparatus, or to operate, as in this case, sewing the fragments together, using strict antiseptic precautions and drainage. Could the element of danger which follows a compound fracture in which the knee-joint is opened, even under such precautions, be eliminated, as it has not yet fully been, no doubt in healthy subjects this cause of immediate operation would be generally accepted. This patient recovered, with a limb the utility of which is hardly impaired, and the success obtained with close union of the fragments is much better than after the employment of the apparatus in ordinary use, excepting in a few isolated instances.

Walter T——, aged twenty-five, a carpenter, was unloading a van on July 19th, and on getting down he caught his heel between two pieces of wood and was thrown off the cart on to an iron grating in the roadway. He distinctly remembers hearing something snap, and on trying to rise was unable to do so. He was brought to the hospital and found to have fractured his left patella transversely. On admission a back splint was applied, the leg bandaged, and the patient put to bed, an ice-bag being kept applied to the joint, which felt hot, and was somewhat swollen and tender.

July 24th.—This afternoon Mr. Bloxam made an incision two inches and a half in length immediately over the patella, opening up the bursa and clearing out the blood and clots. He then separated the anterior surface of the patella from the aponeurotic tissue, and a hole was then drilled through the upper fragment obliquely from above downwards, and a similar one in the lower fragment in the opposite direction. A piece of stout silver wire was then passed through the holes and tightened, and the edges of the fractured patella brought into close apposition. A counter-opening was made to the outer side of the knee-joint, and a drainage-tube inserted. The edges of the incision were then stitched together with silver wire sutures, another drainage-tube being inserted. The whole operation was performed antiseptically, and the limb placed on a long back splint and slung.

25th.—Patient passed a restless night, and was given a one-grain opium pill at 8 P.M. and again at 12. He has no pain in the knee. Temperature 100·8°.

Digitized by Google

27th.—Patient is feeling comfortable, and takes his food well. Temperature 99°. Tongue clean.

28th.—Wound was dressed to-day with antiseptic precautions; it looked healthy, and the edges seemed to be healing by first intention. The drainage-tube was shortened by half an inch. Patient slept well last night, and is in no pain. Temperature 98·8°.

31st.—Patient is doing well. The drainage-tubes were removed and the wound syringed, and everything looked healthy.

Aug. 12th.—The wound was dressed again this morning and the sutures taken out. The wound into the joint is quite healed, and the one over the patella is reduced to a point. Zinc ointment was applied to several inflamed patches in the neighbourhood. Antiseptic dressing was reapplied.

24th.—Patient can bend the knee with ease, and everything seems to be going on well.

28th.—The splint was removed to-day and fastened on to a pillow. Patient was allowed to get up this afternoon, but not to use his leg.

Sept. 1st.—Patient left the hospital to-day with good union of the patella. He was instructed to use his leg very carefully for some time to come.

OSTEO-SARCOMA GROWING FROM THE SECOND CERVICAL VERTEBRA AND PRESSING ON THE SPINAL CORD.

The following case of retro-pharyngeal growth is very interesting, the symptoms pointing to pressure on the spinal cord and its membranes, with some irritation of the medulla oblongata. It is to be regretted that the further progress of the disease with the sequence of the symptoms which developed later, and a post-mortem examination, could not be added to the account.

Ann D——, aged forty-eight, a widow, was admitted on July 22nd, under the care of Mr. Bloxam, with the following history. She had been quite well up to the last two years, when she noticed that she was getting very drowsy during the daytime—to such an extent, indeed, that she could not accomplish her household duties. She was, moreover, continually being bruised by tumbling against the furniture in consequence of her falling asleep when standing still for a moment. Three months later she felt a lump in her throat, which did not cause her much pain, but inconvenienced her a great deal, and this it has continued to do since. Nine months later her speech began to be involved, the patient experiencing difficulty in articulating distinctly. Her eyesight also suffered, but her hearing was not sensibly impaired. About a week ago her head began to drop to the right, and she had a numbness or want of feeling in her hands. She had an "indescribable feeling" at her heart, and at times her breathing was very short. Curiously enough, she does not sleep well at night, although so drowsy during the daytime. She says she is a good deal thinner than she was two years ago. Family history *nil*. She had several miscarriages after her first child, but no history of syphilis can be elicited. She has had several living healthy children since. The patient herself has only had typhoid fever and small-pox since childhood.

Condition on admission.—Patient is thin and ill-nourished, and her appetite is poor. Pulse slow, regular, and non-compressible. She suffers from constipation, but passes a good deal of urine. Her tongue is furred, and deviates to the right when protruded. Her head also is tilted towards that side. She appears to have great difficulty in keeping awake. Her speech is thick, and can scarcely be understood. When requested to grasp anything, she can do so momentarily, but her grip is soon relaxed, and any object she may be holding falls without her being conscious of any intention to "leave go." Patient says the lump in her throat does not interfere with her swallowing. The pupils are contracted. She can walk steadily. The soft palate is relaxed and deviated.

July 25th.—The patient's condition is the same as on admission. On opening the mouth widely and depressing the tongue, an elastic but firm tumour is seen situated at the back of the pharynx on the right side and pushing forward the palate, which itself does not appear to be involved. The swelling extends across the median line, and as far outwards as the palatine arches; it reaches upwards as far as the hard palate, and downwards below the level of the soft palate. The growth is firm, fixed, and nodulated. No glandular enlargement can be detected in the cervical region. The patient can blow freely through both nostrils. She declined to allow any operation to be performed, and left the hospital. She died within a month or two after her voluntary discharge.

HOSPITAL FOR CHILDREN, PENDLEBURY.

ULCERATION INTO THE GREAT VESSELS OF THE NECK, LEADING TO HÆMORRHAGE, IN A CASE OF SCARLET FEVER; DEATH TEN DAYS AFTER LIGATURE.

(Under the care of Dr. ASHBY).

EXTERNAL hæmorrhage from the great vessels being in scarlet fever a condition of some rarity, the following record will prove interesting both on account of its clinical and of its pathological features. For the account of the case we are indebted to Mr. Macalister, senior resident medical officer.

The patient was a little boy aged two years, admitted into the fever ward on the fourth day of the disease, presenting the usual symptoms of scarlet fever. There was nothing remarkable about the case except that the neck was much swollen on either side, hard, and painful (cellulitis and enlarged glands), and had become so on the day before admission. It is worthy of note that the throat affection was of a mild character, the tonsils being enlarged and injected, but having no deposit upon them. The temperature gradually fell after the sixth day, and on the eighth day was normal, the child apparently becoming convalescent.

On the tenth day the temperature again began to rise, but nothing could be discovered to account for this, except the condition of the neck. Three days later, fluctuation being suspected on the right side, a careful incision was made over the softer part down to the deep fascia, which in turn was opened, and the wound enlarged with dressing forceps. Plenty of serum, but no pus, escaped at the time, but on entering a director on the following morning a quantity of thin watery-looking pus flowed along its groove, and the wound was drained and continued to discharge freely during the following week. During this period the temperature became better, varying between 97·6° and 101·6° in twenty-four hours, but the child continued very weakly, and showed no tendency to improve, although treated with appropriate remedies.

On the twenty-fourth day of the disease, the nurse, who had left the child but a few minutes previously, discovered him saturated with blood, which was freely escaping from the external wound in the neck. She very promptly arrested this flow by plugging the wound with the finger. When seen almost immediately afterwards, the child was extremely collapsed and blanched, restless, and sighing deeply. No radial pulse was perceptible. Pressure having been applied over the vessels, stimulants were given both by mouth and hypodermically, the pelvis was raised and the extremities bandaged, and in the course of an hour the wound was enlarged and explored. The muscles and glands were found bared and the surrounding tissues softened; the fascial structure had in great measure disappeared. On removing the pressure the bleeding did not of itself recommence, owing to the collapsed state of the boy, but on an attempt being made to plug the wound with strips of carbolised lint, at once a flow of bright arterial blood took place, and in such amount as to render it evident that either the main vessel or a large branch must be the seat of hæmorrhage, and further and deeper exploration failing to discover the bleeding point, it was decided to ligature the common carotid. This was done immediately below the omo-hyoid, which was divided to give more room. The discovery of the vessel was rendered a matter of great difficulty, partly owing to the inflammatory matting together of the tissues and in part to the absence of pulsation, so that there was little to guide one in distinguishing between the vein and the artery. As a result of this the sheath of the vein was at first opened slightly, the blue colour being the first indication of the mistake. A small opening was made in the carotid compartment and a strong catgut ligature applied. No anæsthetic was given, and the patient showed no indication of pain throughout the operation. Judging roughly from the amount of blood on the surroundings about seven ounces (fluid) must have been lost. At 2·30 P.M., an hour after the operation, the patient was still pulseless and unconscious. Ether was injected together with two minims of solution of sulphate of atropine. At 4 P.M. he seemed to be dying, gasping at long intervals, and extremely blanched. Temperature 95·6°, and

Digitized by Google

as a *dernier ressort* two ounces (fluid) of a solution of sulphate of soda (two ounces to the pint) at 100°F. was slowly injected into the loose cellular tissue of the axilla, where it formed a large swelling. It was very rapidly absorbed and the child became better, took some peptonised milk, and at 8 P.M. was quite conscious and taking his nourishment well. At midnight he was very restless, but less blanched. Pulse 180, quite perceptible at wrist. The feet and legs were now enclosed in a thick covering of cotton-wool, the bandages reapplied, and one minim of tincture of opium given. Temperature 102°.

Twenty-fifth day.—Passed a restless night, sleeping at intervals. The pulse is full, bounding, and hard, 176. He takes his food well. Temperature 103°. The wound looks rather red; dressed with iodoform. On removing the coverings from the extremities, the toes of the right foot were found to be almost black, and colder than the surrounding parts. Some bullæ had also appeared on the dorsum of the foot and ankle, and there was no sensibility in these parts. Warm cotton-wool was applied.

During the next few days there was continued improvement. The wound kept sweet and looked healthy. The toes recovered in great measure, only about half of the terminal phalanx of each drying up, and a line of demarcation forming between this and the recovered portion.

On the thirtieth day, at 7 A.M., some oozing took place from the wound, which at once stopped on the application of cold, and was at first thought to have occurred from some granulations; but four hours later a sudden gush of dark venous blood took place, and, on exploring, the vein was found in part bared, but the bleeding point could not be determined. The hæmorrhage recurred three times within the next twenty-four hours (plugs being employed to arrest it each time), and at 4 P.M. on the thirty-first day, during a fourth attack, Mr. Wright made a careful examination, and found a small opening in the sheath of the vein from which the blood escaped; this he enlarged, and, two points of hæmorrhage becoming evident, he ligatured the vein above and below these, but immediately afterwards the blood flowed from a perforation still higher up, and he applied a third ligature above this. The tissues of the vein were soft and friable, tearing away in the forceps.

At midnight on the thirty-second day hæmorrhage again occurred, and this time from a part of the vessel lying so high up and deep in the neck as to be inaccessible to ligature. It was at this time noted that the child had complete paralysis of the left upper limb and paresis of the left leg. He could not shut his left eye. Sensibility was also impaired on the left side. The intercostal muscles and diaphragm acted equally, and the pupils were equal and reacted readily. He had remained in a condition of great prostration since the venous hæmorrhage commenced.

Thirty-third day.—Purpuric spots appeared on the right ear and cheek; he now, for the first time, absolutely refused nourishment, and nutrient enemata were given. He gradually became weaker, and died on the thirty-fourth day of the disease.

Necropsy.—There was general bloodlessness of the organs, which appeared otherwise healthy. The blood was pale, and the spleen enlarged (weighed three ounces). The brain was anæmic. No emboli were found. The thoracic viscera and structures on the right side of the neck were removed *en masse*, and on subsequent dissection presented the following characters:—The carotid artery, from the seat of ligature up to the point of bifurcation, had entirely disappeared, and the walls of the remaining upper part were so thinned and soft as to tear like wet tissue paper when seized with the forceps. Below the ligature the vessel was filled with clot. The vein was in a similar softened condition and had four perforations, one of these almost immediately above the highest ligature and beneath a gland. The sheath, which had disappeared both from vein and artery from a little below the point of carotid ligature to the bifurcation, was separated from the vessels above and below these points, and in the anterior mediastinum, immediately over the pericardium, was expanded into a small cavity containing thin purulent fluid.

Remarks.—Although sloughing into the internal carotid from the throat is comparatively common in scarlet fever, there are very few cases recorded where the hæmorrhage has occurred from without. Among others, Dr. Kennedy in his account of the epidemic in Dublin 1834-42 reports three cases, in two of which the vein alone was opened into, and in the third there was no post-mortem. In the latter and one of the other cases the blood escaped from an opening which had been made into an abscess some days previously; in the remaining case a large slough formed, dissecting out glands, muscles, and bloodvessels. Fatal hæmorrhage through the external auditory meatus has occurred several times, as recorded by Graves, Professor Porter, and Dr. P. J. Hynes, and in one such case the child recovered after the carotid had been ligatured by Mr. Bennett May. It would seem that the destructive processes leading to this perforation of the vessels are of two kinds. In the one, the peri-glandular cellulitis and abscess is followed by softening and dissolution of the tissues (colliquative necrosis). In the other, large sloughs form and separate, laying bare many of the deeper structures; but, generally speaking, the vessels, and more particularly the arteries, are the last to be destroyed, and several times complete recovery has ensued where the sheath of the carotid and the internal jugular has been exposed without the occurrence of hæmorrhage.

NEWCASTLE-ON-TYNE INFIRMARY.

LARGE LOOSE CARTILAGE SUCCESSFULLY EXTRACTED FROM THE KNEE-JOINT OF A PATIENT AGED EIGHTY YEARS.

(Under the care of Mr. FREDERICK PAGE.)

M. G——, a woman aged eighty, was admitted into the infirmary on Nov. 5th, 1885, with the following history. For the last five or six years she had suffered from pain in the left knee-joint, and was aware of a loose body in it which she was able to push from one part of the joint to another. On Nov. 1st she fell upon her knee. Considerable pain and swelling of the joint followed, and for this she was admitted into the hospital. The limb was kept at rest on a MacIntyre splint.

Dec. 15th.—All inflammation having subsided, a free incision was made into the joint under carbolic acid spray, and a loose cartilage extracted. The cartilage was peculiar in appearance, not unlike a flat oxalate of lime calculus. In length it measured 2 in., in breadth 1¼ in., and ¾ in. in thickness. It weighed 250 grains. The wound healed kindly.

29th.—The patient was able to move about the ward readily.

The case is interesting from the age of the patient, and from the size and peculiar appearance of the loose body.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Enteric Fever at Suakim.

AN ordinary meeting of this Society was held on Tuesday last, Dr. George Johnson, F.R.S., President, in the chair. Drs. Robert Maguire, Harrington Sainsbury, John McDonagh, and Messrs. C. H. Golding Bird, and B. Wainewright were elected Fellows of the Society.

Dr. J. E. SQUIRE read a paper on Enteric Fever at Suakim, with some cases of Malarial Enteric or Typho-malarial Fever. By the courtesy of the medical officers of the Suakim Field Force, the author was entrusted with the charge of a division of the Base Hospital at Suakim, and was thus enabled to see much of the fever which occurred among the troops. The analysis of nearly eighty cases shows that, though the large majority—about seventy—were of the ordinary enteric fever type, as verified in two cases by necropsies, some were so modified by climatic causes as to merit the designation of malarial enteric. Two or three showed stronger evidence of malaria. One of these, believed to be enteric during life, was found post mortem, after four weeks' illness, to have no specific enteric lesions at all; to this class of cases the term "typho-malaria" might be restricted. In two of the fatal cases hæmorrhagic effusions occurred under the conjunctivæ or in some parts of the skin; these cases were not due to scurvy, the diet of the troops being varied with fresh meat and vegetables. Typhus was unknown in the force. Diarrhœa was a prominent symptom in all the cases. As regards the cases of enteric fever, it would seem that the disease was imported from Cairo, and that the infection was spread by the air; the use of none but condensed water for

Digitized by Google

drinking and cooking purposes excluding water as a means of transmission. In opposition to the views of some Indian and army medical authorities, the seasoned troops, represented by the East Surrey Regiment from India, were attacked earlier than those unused to tropical climates, as represented by the Guards who came direct from England, and the mortality was not proportionally greater among the younger soldiers. Cases of enteric fever were admitted into the Base Hospital soon after it was opened, in March; the malarial cases did not occur till some two months later. Seventy-three temperature charts and some cases in full were given in illustration of the points referred to in the paper.—Dr. GEORGE JOHNSON considered that enteric fever could originate from other sources than contaminated water, and mentioned some cases in illustration of its origination from sewer-gas.—Surgeon-Major MEYERS said at the commencement of the campaign he had seen cases of "dysenteric diarrhœa" at the Base Hospital, but this epidemic disappeared when the Guards moved to Tambouk. Whether true enteric fever was the nature of the majority of cases of febrile illness at Suakim he felt himself in doubt, but was inclined to think it was not true enteric, and was rather disposed to regard dysentery as at the bottom of it, which would not be surprising when we bore in mind the sort of emanations from a soil composed of dry fæces and sand, the latter constituent having no deodorising properties. Rose spots during life and typical ulceration after death were, in his experience, rarely met with. The peculiarity of many necropsies was a remarkable form of extensive sloughing round the ileo-cæcal valve, totally different from what he had seen in enteric fever in this or any other country.—Dr. MARSTON dwelt upon the great influence of age and recent arrival in a tropical or subtropical country in increasing the susceptibility to enteric fever, and he illustrated this by some forcible figures showing the percentage liability to die of this fever of men under twenty-five years of age during their first and second years of service in India, as compared with older men of longer service in that country. The amount of enteric fever in a newly-arrived regiment, as compared with a more acclimatised one, showed the same thing. The facts came out year after year with a monotony which left no room for doubt. And it was the same thing in war; in Afghanistan and Egypt, and in the French Army during the campaign in Tunis. As the second case of enteric fever occurred at Suakim in the Shropshire regiment the day after that of the Surrey regiment, it was impossible for the latter to have been the cause of it. It must be remembered that recent experience has proved that the incubationary period could be prolonged to six or even seven weeks. The cases of fever seen in tropical climates were, in his experience, true enteric fever, presenting its clinical features during life and its morbid appearances in fatal cases. As regards typho-malarial fever, there was no evidence of its existence as a new and perfectly distinct disease, although, of course, a malarious subject might be attacked with typhoid fever and exhibit symptoms of both diseases.—Dr. D. DREWITT had seen cases of fever at Palermo and Sicily in which there were definite sets of symptoms; suggesting that we had to deal with a "chemical" union of typhoid and malarial fevers, rather than with a mechanical mixture. In Dr. Whipham's history of the American rebellion there were narratives showing the great variety of types of disease that were constructed of the union of apparently different maladies; any combination of typhoid, dysentery, and ague being liable to be met with.—Dr. SINCLAIR THOMSON believed that the nature of the soil determines the form of typhoid of which he distinguished various types; the abdominal and diphtheritic being two chief ones. When water was the source of the poison the abdominal symptoms prevailed; but when sewer gas, then the throat was more affected and nervous symptoms were prominent.—Dr. DON had had twenty years' experience of typhoid fever, and had written a paper in a Blue-book for 1870 on the subject. Speaking of typhoid fever in subtropical latitudes, he recognised the civil view which interpreted an outbreak of enteric fever as due to some pre-existing case, and the military view which allowed that the disease could originate *de novo* under certain climatic, dietetic, and like causes. He believed that a nutritive intestinal change preceded the appearance of typhoid fever, and considered that it was just a chance whether this precedent intestinal disease should develop into typhoid fever or not. He declared emphatically his opinion that enteric fever could originate *de novo*.—Brigade Surgeon GRIBBON had medical charge of the *Ganges*, and had no doubt whatever that the disease was enteric fever, for he saw characteristic ulcerations in some necropsies. Most of the cases on board were convalescent; some had been sent with the diagnosis of "remittent fever," "heat apoplexy," and the like, but he believed they were really enteric also. Suakim was not, in his opinion, a malarial locality; northerly winds tend to empty the harbour and southerly winds to fill it, but there was no actual tide; stenches arose during the prevalence of northerly winds. The first case on the *Ganges* occurred in one of the orderlies, curiously enough, and only convalescent patients were then abroad; the orderly had been ashore a few times, but his dietetic and hygienic arrangements aboard were sound.—Dr. BROADBENT said the paper was valuable for the discussion that it had raised, and when coördinated with the larger set of observations of Dr. Marston was still more valuable. The fact of the occurrence of enteric fever at certain ages and on recent arrival in a country teaches nothing as to the specific or non-specific nature of the disease. He felt convinced that there was some other fever met with in tropical and sub-tropical climates, and distinct from, though simulating to a certain extent, the course of typhoid fever. The second tropical fever could hardly be enteric fever modified by climatic and other conditions. Experience has shown that we require some distinct name to express this second affection, and "typho-malarial" was perhaps the best one that could be discovered for a fever which was even more protean than enteric fever in its clinical course. Reference was made to a history in which five officers figured, and had been under the same conditions in Malta; of these, three developed an illness soon after—one was said to have subacute rheumatism, another enteric fever, which lasted three months and ran an irregular course; the third case came under Dr. Broadbent's own care, and it had nothing in common with enteric fever, if we except the fact of protracted high fever with some intermissions. He said that Murchison in his Indian experience had remarked on the protracted duration of the high temperatures of these cases, which resembled in nothing the pyrexia of enteric fever. He considered that it was very necessary to differentiate these fevers, which are still confused, for the typho-malarial form departs in the most complete way from enteric fever, being really a distinct fever that simulates typhoid fever only to a very limited extent.—Dr. HARDIE considered that an epidemic limited to a few individuals in the community attacked was evidence of the typhoid nature of the illness; the appearance of the "typhoid tongue" on the third or fourth day he regarded as of considerable diagnostic significance.—Dr. SQUIRE, in reply said he was glad to hear Dr. Broadbent express the opinion that there were two distinct diseases to deal with, for it concurred with his view stated in the paper.

MEDICAL SOCIETY OF LONDON.

Subperiosteal Resection for Acute Necrosis.—Cerebral Abscess and Empyema.

AN ordinary meeting of this Society was held on Monday last, Dr. W. M. Ord, President, in the chair.

Mr. BERNARD PITTS read a paper on Subperiosteal Resection for Acute Necrosis, and exhibited a living specimen of the first case, which was that of a girl aged fifteen, who was admitted to St. Thomas's Hospital on Nov. 25th, 1882, with swelling of the lower end of right tibia. For one week the swelling and pain had been present, and an incision was made above the ankle, a quantity of matter escaping. At the time of admission the girl was in a prostrate condition, with a temperature of 102°. The incision was freely enlarged and the limb placed on a Neville's splint. The patient steadily lost ground, and on Dec. 16th, or thirty-five days from the beginning of the disease, an operation was performed, in which the lower two-thirds of the tibia and ankle-joint were exposed. The lower half of the tibia was found to be necrosed, with separation at the lower epiphysial line; the epiphysis was almost entirely destroyed, a mere shell of bone representing the external malleolus remaining; the upper surface of the astragalus had lost its cartilage, and was granulating. There was a line of separation at the upper end of the necrosis; this fact decided Mr. Pitts to try to save the limb, which it was till then thought required amputation to save life. The tibia was sawn through a little above the line of demarcation, so that three-fifths of

Digitized by Google

the tibia (measuring five inches and a half) were removed, the periosteum at the back of the bone being carefully preserved; it was felt to be roughened by the presence of a fine layer of osseous granules; the surface of the astragalus was thoroughly scraped, and the epiphysial remains removed. Recovery proceeded rapidly, and on April 28th the patient left the hospital, the wound being healed, with the exception of two sinuses at the upper part. On June 23rd a small residual sequestrum was removed, and on August 21st a sinus of the foot was scraped. Since then the leg had remained perfectly sound. It is now in a very useful condition, with but slight deformity—shortening of three-quarters of an inch, and a tendency to varus, with increased mobility at the tarsal joint. Four years have elapsed since this case came under Mr. Pitts' care, so that he has had time to observe the ultimate result. The second case, a boy aged seven, had been under Sir William Mac Cormac's care from October 11th, 1881. The disease was situate at the same site as in the previous case. An incision was made over the internal malleolus, which allowed the escape of some exudation. Twenty days after the first onset of symptoms Sir William detected separation at the epiphysis, and two inches and a half of the tibia were excised. Regeneration of the bone rapidly took place, and the patient was up on Dec. 23rd. Some months later Mr. Pitts saw the case, and there was but little shortening or deformity. Mr. Pitts said he divided cases of acute necrosis into five classes and indicated the treatment:—1. Acute necrosis of the entire shaft, with separation at the epiphyses, ought to be treated by removal of the dead shaft. 2. Where one or both joints were implicated also, early interference was more imperatively demanded, but in some cases amputation would be required. 3. For limited necrosis, time for complete separation of sequestrum might usually be given. 4. Acute necrosis of either end of a long bone was illustrated by the second of the cases related. 5. Of acute necrosis with total destruction of the epiphysis and involvement of the joint, the first case was an example, showing that the limb may sometimes be preserved.—Mr. H. H. CLUTTON said Mr. Pitts' case proved that the surgeon need not hesitate to remove living bone with the dead, for a good result could still be obtained.—Mr. J. H. MORGAN mentioned similar cases, and some that came under his own treatment.—Mr. WALTER PYE said the case was precisely like one that he had shown at the Royal Medical and Chirurgical Society. The fibula may act as a direct splint in maintaining the shape of the limb, and in cases of entire necrosis of the diaphysis of the tibia he thought that the fibula was most useful in the further course of a successful case; indeed, he doubted whether a good result could be obtained without it.—Mr. PEARCE GOULD remarked on the adhesion of the new bone to the dead, and questioned how far this might be taken as evidence of the life of the original bone, whether, indeed, the whole of the shaft of the tibia was dead. The difficulty of knowing how deep the necrosis extended was rather against the early removal of sequestra, for much new bone might be removed, and the ultimate issue of some cases showed that the sequestrum was very small compared with what was expected. Cases illustrating these points were narrated. The general condition rather than the state of the local lesion should probably guide the surgical treatment.—Mr. BERNARD PITTS, in reply, said that he ought to have added a further division in his classification—viz., to include entire necrosis with complete destruction of the epiphysis. He did not quite know how to determine the depth of necrosis unless the surgeon adopted the plan of M. Ollier of Lyons; but such an operation was of doubtful value, and a bloodless exploration hardly possible.

Dr. D. W. FINLAY read a paper on Empyema with Cerebral Abscess which appears in full in another column.—Dr. HADDEN narrated a similar case in a man aged twenty-eight, in whom the pyo-pneumothorax was due to a phthisical cavity; abscesses were found in the frontal and occipital region of the brain.—Dr. DE HAVILLAND HALL also related a similar case in a young woman, in whom the cerebral abscess appeared to have existed for some time.—Mr. BERNARD PITTS said that in the case Dr. Hadden referred to he found that the drainage-tube was kinked by new bone, necessitating extensive resection of the ribs.—Dr. J. J. PRINGLE read the notes of a somewhat similar case, which differed, however, in the important particular that it recovered. It is published in the Middlesex Hospital Reports for 1883.—Dr. BROADBENT remarked that the embolism started from the pulmonary circulation: a portion of a thrombus became detached from a thrombosed pulmonary venule, and so rapidly reached the left ventricle. He agreed that frequent washing out of empyemic cavities was to be deprecated.

ACADEMY OF MEDICINE IN IRELAND.

Albuminometry and Esbach's Tubes.—Embolism of the Central Artery of the Retina.

AT the meeting of the Medical Section on Dec. 18th, 1885, Dr. CRUISE read a communication on the Quantitative Determination of Albumen and Urea in Urine. The simple clinical methods which he demonstrated were those of Dr. G. Esbach, and which have recently been described in our columns (THE LANCET, Jan. 23rd, p. 153).—Dr. A. W. FOOT, having used Esbach's test for two or three years, found one source of dissatisfaction with it. Esbach's direction was to read the number of grammes per litre on a graduated scale after allowing the urine and reagent to stand for twenty-four hours; but in twenty-four hours more a very much less degree would be registered. So far as he had read, Esbach had not noticed the fact that the precipitate condensed day after day into smaller bulk.—Dr. TICHBORNE did not think this objection had been proved. The test was an approximation for practical purposes, and Dr. Esbach had graduated his tubes to be read after standing a given time. Of course, precipitates standing would gradually get more dense; but the tubes were graduated on the understanding that they would be read after standing twenty-four hours. When picric acid came out, he tried some experiments as a qualitative test against the old nitric acid test, which, when properly applied, was one of the best. When poured down the side of the test-tube, he found the nitric acid test was slightly more sensitive than picric acid. At the same time, picric acid had the great advantage that, when visiting, it was easily carried in one's pocket. In urine there were occasionally albuminoid bodies that could not be got at by the ordinary methods of coagulation or boiling.—Dr. J. A. SCOTT pointed out, as an objection in connexion with picric acid, that other things besides albumen came down in the cold solution if added to it—for instance, where the patient was taking quinine. In estimating the quantity of urea there was some trouble in calculating according to the tables supplied. Other methods enabled an estimate to be made by percentages, thus dispensing with book-work.—Dr. WALTER G. SMITH had himself twelve years ago, in the Adelaide Hospital, tried picric acid as a qualitative test, and he saw no reason for preferring it to the better-known and more old-fashioned test which had not yet been dispossessed from practice. Experiments made in Christiania showed that the most delicate qualitative test was the old nitric acid test, and accordingly Heller's method of using nitric acid as a test had maintained its pre-eminence for the recognition of small amounts of albumen.—Dr. FALKINER said the test might be clinically correct as regards the state of albumen in the urine, but it was not absolutely correct. The nearest approach to a correct quantitative clinical test was Oliver's method, whose basis was also citric and picric acid, the quantity of albumen being estimated by the disappearing point of a dark line which was placed behind a test-tube of known dimensions. With regard to urea, Professor Emerson Reynolds had some years ago made a complete apparatus for estimating the amount of urea, not by measuring the gas but the quantity of water displaced by the gas evolved, and he gave a table of calculations.—Dr. FINNY said he had tried Esbach's method, and, not considering it useful even in the way of saving time, he had discontinued it. Indeed, it was no safer than the old method of boiling the urine and allowing it to stand. There was one great objection to its use which he had found in testing urines—namely, that where there was a large amount of albumen the test lost much of its readiness as a clinical method, as it had to be so frequently repeated before the urine could be sufficiently diluted to render it an accurate test for albumen. Having tried both picric and nitric acid, he found that in the majority of cases the nitric acid test was the most accurate and trustworthy.—The PRESIDENT, like Dr. Foot, had observed the progressive condensation of the coagulum. According to Esbach's notion, the reading should be made after twenty-four hours. As to the albuminoids, it was true that a certain amount of confusion and difficulty would arise, but the method sufficed for general

Digitized by Google

clinical purposes without seeking scientific accuracy. The same difficulty had been raised by Dr. Scott with regard to quinine and peptones, but when it was known the patient had taken quinine allowance could be made. There was no difficulty in reading from the tables the results in the urea test, as where the two numbers crossed it could be seen at a glance. He had been using the hypobromine solution for some months, and it had kept. Whenever he had a doubt as to the efficacy of the solution, he added a little more; thereupon, if it effervesced or fresh decomposition set in, it was clear there had not been sufficient; or if the solution lost any of its olive-oil colour, he added a little bromide. The absolute quantity of the hypobromine solution was unimportant, provided it was rather in excess. He had tried Oliver's test for the quantitative analysis of urine and of sugar, and he found it difficult to determine from the obscurity of the light the exact point. Besides, Oliver gave only a percentage, from which it was necessary to calculate back, and his test of sugar was still more difficult. The great advantage Esbach's instrument possessed was that the analysis could be made in about five minutes, and probably with as much accuracy as any other.

Mr. ARTHUR BENSON read a paper on a case of Partial Embolism of the Inferior Division of the Central Artery of the Retina associated with repeated attacks of Chorea. The patient, a house painter, aged twenty-one, had had rheumatic fever seven years ago Three years ago he had an attack of left hemichorea. Two years ago another attack of more general chorea, and last year a third attack of chorea. On the 14th of last October he suddenly became blind of the right eye; in a few minutes vision began to clear from below upwards, and in fifteen minutes the lower half had quite cleared to the horizontal line, passing through the fixation point. There the improvement abruptly ceased, and has not since proceeded. The ophthalmoscope showed œdema of the lower half of the retina and "a cherry-red spot" at the macula. The vessels (veins and arteries) were all filled with blood, and pulsation could be produced with pressure, showing circulation had been re-established at that time—i.e., fifteen hours after the eye became blind. The vessels of the lower half of the fundus were not quite so plumply filled as those of the upper half. In a few days there were evidences of atrophy of the disc and shrinking of the retinal vessels in its lower half; and as the œdema of the retina diminished, the atrophic changes increased and the vessels shrank markedly. The diagnosis was that an embolus for a time partially blocked the central artery before its bifurcation, and subsequently got shifted into the inferior division and partially blocked it, for the vessels were all carrying blood in the right direction, showing that the obstruction was not complete. The patient had never had any similar attacks. His heart and kidneys were carefully examined, and nothing abnormal discovered. He was in other respects healthy, and there was no evidence to show where the embolus came from. The case was of interest as bearing upon the embolic theory of the pathology of chorea.—Dr. NIXON said there had been no suggestion where the embolism came from. The patient was stated to have had a history of an attack of rheumatic fever, yet the heart was perfectly sound. However, the fact that the patient had had an attack of hemichorea in the left side, and that he had an affection of the right retina, clearly showed that the disease was embolic, and it was difficult to say where it came from, except from the heart. Where there was no peripheral disease with which to connect the embolism, it must be assumed that it came from the heart.—Dr. PURSER observed, as regards Dr. Nixon's assumption that the existence of embolism necessarily proved disease of the heart, that not one out of fifty cases came from the valves of the heart. In a great many cases the deposits on the valves of the heart were too firm to be washed off. It was much more likely to have resulted from thrombi which became broken up and were carried away in the current of the circulation. The examination of the emboli showed that they do not come from the valves of the heart, but from coagula in the bloodvessels.—Dr. POOR said the patient had been under his care, affected with hemichorea on the left side, in his arm, then the leg, and lastly the face. At that time he had no cardiac murmur, but he gave a history of rheumatism, and that he had had a rheumatic ailment about nine months before the attack of hemichorea. It was then the "fad" to treat chorea hypodermically with arsenic, and the patient was injected with it twenty-six times, beginning with five and going up to thirty minims. At fifteen the strength was doubled to minimise the bulk, nor was it stopped until a quarter of a grain of arsenic had been injected under the skin. He believed that camphorated water would have done as well.—Dr. BENSON, in reply, said he had seen but a very small percentage where a distinct heart lesion was discoverable.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Jan. 15th, Professor Jessop, President, in the chair.

Thrombus.—Dr. CHURTON showed a heart containing a softening thrombus the size of a large walnut in the apex of the left ventricle, and two smaller masses as large as beans. The bases of the latter were not entangled in trabeculæ, but lay upon perfectly even surfaces on the septum and posterior wall. Another heart was shown in which there was a broad patch of endocarditis covered with vegetations, extending from the anterior flap of the mitral valve to the upper limit of the auricle, the rest of the auricular endocardium being quite smooth.

Antiseptics in Operations on the Eye.—Mr. BENDELACK HEWETSON read a paper on this subject, in the course of which he dwelt on the value of the eucalyptus spray, which he suggested some time since as an additional aid towards making cataract and other major operations on the eye completely antiseptic. He has observed in a large series of cataract operations that there has been less irritation and pain following the operations, the wounds have healed more quickly, and mishaps, such as eyes suppurating after the performance of such operations in hospital as well as private cases, have largely decreased. In the case of cataract operations the following precautions were taken:—1. Immediately before operation the eye was washed with carbolic lotion, 1 in 80. 2. Cocaine, if used, was applied in an aseptic solution. 3. All instruments were washed in carbolic lotion, 1 in 60. 4. The operations were performed under the eucalyptus air spray. 5. The eye was subsequently covered by a layer of salicylic silk enclosed in two layers of absorbent wool, and freely exposed to the eucalyptus spray.

Removal of Os Calcis &c. for Strumous Disease.—Dr. ALFRED SWANN, showed a patient aged eight from whom he had three years previously removed the os calcis, astragalus, and the malleoli, on account of strumous disease of eighteen weeks' duration, which had originated without any apparent cause. The child was able to run and walk perfectly, the movements of the ankle-joint appearing normal. Dr. Swann also showed the bones removed, which presented the appearance of strumous ostitis.

Labio-glosso-laryngeal Paralysis, with Atrophic Paralysis of the Hands.—Dr. BARRS read the report of this case. The patient, a man aged twenty-nine, had been continuously under Dr. Barrs' observation since Aug. 25th, 1885, when he presented himself in the out-patient room complaining of nasal voice and some slight difficulty in swallowing. In addition to the marked alteration in the voice, there were noticed a want of movement of the palate when touched and impaired lip movements for all purposes of articulation and other functions. At this time no appreciable impairment of the tongue movements was noted, and beyond passage of food into the nose there was no affection of deglutition. There was no history of syphilis, diphtheria, or lead poisoning. In September the tongue was first noticed to be tremulous and unsteady, but it could be protruded to normal point, and there was marked increase in all other symptoms. In October some loss of power in the left thumb was reported, and in November there was marked wasting of the muscles of both hands, but much more pronounced on the left side. The electrical reactions of both hand and face muscles were normal, and had continued so up to dates though all manifestations had rapidly increased in intensity. At present there is entire loss of all articulation, his attempts at speech being quite unintelligible; phonation is unaltered, and the laryngoscope shows no change in cord movements. The "visage pleurard" is well marked, and the mouth is large from falling of the lips. The tip of the tongue can just be made to advance beyond the line of the teeth; the organ is the seat of marked fibrillous contractions, and is, perhaps, smaller than natural. The atrophic palsy of the hands is well marked, and the left is assuming a slightly clawed attitude. There is well-marked increase of the

Digitized by Google

wrist and elbow tendon reflexes. The knee-jerks are also increased, and the patient states that now and again the legs become stiff, but no suggestion of any spastic condition is at present to be noticed. The case is now clearly progressing very rapidly towards its complete development, though of only eight months' duration. Dr. Barrs suggested that the case might ultimately develop into one of amyotrophic lateral sclerosis as described by Charcot.

Dr. JACOB showed by the lime-light some lantern views of patients suffering from Bulbar Palsy, and the histological lesions found in such cases. He also related a case at the time under his care, in which there were symptoms of bulbar paralysis combined with wasting of the arms and greatly increased reflex movements of the legs, with a staggering gait.—Dr. CLIFFORD ALLBUTT referred to the views of Duchenne, the first describer of the disease, and remarked on its identity with progressive muscular atrophy being now established, although this was strenuously denied by its original discoverer.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on December 17th, 1885, Mr. R. J. Pye-Smith, President, in the chair.

Extra-uterine Fœtation.—Mr. EDWARD SKINNER related this case, occurring in a woman aged thirty-four. She had good health previously to marriage. She recovered well after a severe labour in October, 1883; menstruated eight weeks afterwards, and then not again for nine months. At the end of February, 1885, the first bone was passed per rectum; several have been passed since. She suffers little or no pain, except after a hard day's work, and just before passing a bone. In August last one of the bones of the head was removed from the rectum. The vagina and rectum were examined, but no opening could be detected. She menstruates regularly, and is still well and going about her duties. Mr. Skinner exhibited the fœtal bones.

Calculi in Kidney.—Dr. LAW related this case and showed the specimens. The patient, a woman aged thirty-seven, had a good family history. She caught cold in August, which was followed by pains in the legs, cold sweats, and great prostration. Pain suddenly commenced on Aug. 28th, whilst lying down, in the hypochondriac region, and was followed very shortly by jaundice. The post-mortem revealed a large abscess in the under-surface of the right lobe of the liver connected with another in the upper part of the right kidney, which latter was filled with irregularly shaped dark-coloured calculi; one of these also lay loose in the lower abscess. The right pleura contained fetid pus, which had made its way through a perforation in the diaphragm. The kidney was opened, and calculi were found *in situ*. The kidney was enlarged and thickened.

Cases of Lead-poisoning from Drinking-water. — Mr. THOMAS related a few cases, out of a number which had come under his observation during the last three years, of decided lead-poisoning from drinking-water. He had in three instances carefully ascertained that no other cause was present. The water usually drunk had been from a pipe coming direct from the main, and having been allowed to run for five minutes a specimen was taken and analysed, when lead, ·21 gr. per imperial gallon or more, was found by Mr. Allen, the analytical chemist, who took great interest in the subject. An average specimen of urine passed during twenty-four hours contained from ·19 gr. to, in one case, ·28 gr. of lead per imperial gallon. In many of these cases the blue line on the gums was not present, but was substituted by a red line. Dr. Thomas had found this not at all uncommon. The indications of the presence of lead had been griping and colicky pains, with constipation, aches in back and limbs, the blue or red line along the gums, disinclination for mental or bodily exertion, dropped wrist, &c. He considered that the condition of water was owing to the acid which the water from one source contained acting on and making soluble the lead of the pipe reaching from the main to the house, and proposed as a remedy in houses the use of a certain filter which deprived the water of its lead and of its acidity. To the water might with advantage be added some carbonate of lime. As a general remedy for the town he suggested for consideration the advisability of utilising charcoal as a filtering agent, carbonate of lime as an antacid, or of both. The question of having the interior of leaden pipes lined with some material not easily acted upon by acids might be considered, but if the former plan were adopted, the latter would not very likely be required.

Dr. PORTER read notes of six cases of Lead-poisoning due to Contaminated Drinking-water, five of which had occurred within the last six months. Three of his patients were employed in the same workshop, where the water had to pass through 300 yards of leaden service-pipe. In every case the symptoms were characteristic, and the water was found to contain more than one-twentieth of a grain of lead per gallon. Dr. Porter alluded to the so-called protective coating produced by hard waters, which was itself a source of danger, a hot dry summer favouring its decomposition. Sulphate of lead was soluble to the dangerous extent of three grains per gallon, and though the carbonate was less so, it might be influenced by water containing an excess of CO_2. Referring to Dr. Thomas's paper, Dr. Porter said he believed a red line on the gums had no connexion with lead, but was often a symptom of dyspepsia. As to the effects of the use of a tooth-brush on the blue line, he had often remarked it was only partial, due to the removal of the tartar, which facilitated its formation, this tending to prove that the deposit of sulphide of lead was interstitial. He had often seen the blue line around molar teeth, disproving the assertion that light was essential to its formation.

The discussion of this subject was adjourned to the next meeting.

CHESTER MEDICAL SOCIETY.

A MEETING of this Society was held on January 8th.

Mr. JAMES TAYLOR, the President, delivered an address, in which, after reviewing the work of the Society during the past year, and alluding to the first death amongst its members, that of Mr. Allan C. McEwen, he passed on to examine the condition, successes and deficiencies of the medical profession, as painted by Bacon at the beginning of the seventeenth century, and to consider how a study of these might still guide us in our means of learning and applying our knowledge.

Aborted Ovum.—Dr. DOBIE exhibited an ovum aborted about the eighth week. The amniotic sac was filled with coagulated blood by which the embryo was surrounded, and which presumably was the cause of the abortion.

Glioma of Brain.—The SECRETARY read notes of a case of Mr. Taylor's and the report of the Pathological Committee upon the brain of a patient, aged forty-two, who was admitted into the Chester Infirmary on Nov. 10th, 1885. He complained of pain on the crown of his head. He walked in an uncertain manner, spoke in an hesitating way, and could not without help raise himself to a sitting posture in bed. He had often fallen down, and on Nov. 16th he walked across the ward and fell suddenly. After that he could not stand without help. After the 20th he had incontinence of fæces, and spoke little. From the 24th he had attacks of violent spasmodic twitching, which were set up by any stimulus such as changing the bedclothes or the cry of a patient in the ward. He died on Nov. 27th. On examination of the brain, a glioma was found in the right frontal lobe, an inch and a half in diameter, and extending about an inch inwards from the surface. The brain-tissue surrounding it was firm and dense, and at its posterior extremity was a cyst containing two or three drachms of clear fluid. Microscopic sections of the tumour made by Mr. Henry Dobie were shown.—Mr. R. S. ARCHER related a case somewhat similar.

Estimation of Urea in Urine.—Dr. KING gave a demonstration of Dr. Squibb's process for the approximate estimation of the quantity of urea in urine. A solution of hypochlorite is made to decompose the urea and liberate its nitrogen, from the measurement of which the amount of urea is calculated.

PRESENTATIONS.—The Committee of the British Hospital at Buenos Ayres have presented Dr. Hanly with a jewel case and an illuminated address as a mark of their appreciation of his important and zealous services to the institution.—The ladies who have attended the recent ambulance lectures at Greenock have presented Dr. W. A. Wilson with a carriage clock, and Dr. J. R. Black with a pocket aneroid, in token of their appreciation of the valuable services rendered in connexion with the classes by those gentlemen.

Reviews and Notices of Books.

Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques. Tome 38: Vac-Vei. Par le Dr. JACCOUD. Pp. 886. Paris and London: Baillière et Fils. 1885.

THE more important articles in this volume of the Nouveau Dictionnaire, which is now rapidly approaching completion, are:—1. Vaccine, by D'Espine. 2. Vagina and Vulva, by Levrat. 3. Varicocele, by Paul Second. 4. Variola, by Balzer and Dubreuilh. 5. Vaso-motor Nerves, by Duval. 6. Vegetations, by Mauriac. 7. Veins; by Beurnier, for their Anatomy, Physiology, and Development; and by Schwartz, for their Surgery and Pathology.

It is pleasant to find that the researches and observations of M. D'Espine have not created in his mind the slightest doubt in regard to the utility of vaccination as a safeguard against small-pox. He gives a rapid sketch of its introduction by Jenner, and discusses, first, the animal origin of vaccine lymph, its evolution in man, and the nature of the virus; and, secondly, the process of vaccination. Vaccine is found in the natural state in the cow, constituting cow-pox, and in the horse, forming horse-pox. It is uniform in its characters, and produces an inoculable but not contagious disease, always benign and creating an immunity for either vaccinal or variolous inoculation. M. D'Espine gives a good and very full description of the two forms above mentioned, and shows how two affections have been confounded under the common name of the grease or horse-pox. The laws in regard to vaccination are more stringent in Germany than in any other country, the act being rendered obligatory before the end of the first year, and revaccination in the course of the twelfth year being also compulsory. The most important recent fact in the history of vaccination is undoubtedly the frequency with which, in view of the danger of propagating syphilis, resort is now had to vaccination direct from the animal. This proceeding, practised in Naples from the very commencement of the century, has only been generally adopted in the principal cities of Europe since the year 1866. No success has attended the experiments of Chauveau to induce vaccine from inoculation of either the horse or cow with variolous lymph. Variola continues to produce variola, and vaccinia vaccinia. M. d'Espine adduces many statistics of interest. Thus, in the State of Würtemberg, the experience of thirteen years and of nearly half a million of vaccinations, shows that the failures occur once in 129 vaccinations, or 0·7 per cent. Again, in relation to the duration of immunity from variola after vaccination, the revaccinations in Germany show that at the age of twelve to fourteen the influence of the first vaccination is singularly enfeebled. One patient is known who has been vaccinated five times at intervals of several years with success. It appears that vanity is so strong in some of the gentler sex that they prefer to be vaccinated on the thigh to the arm, on account of the disfigurement occasioned by the scar. M. D'Espine, we know not with what amount of truth, accuses the Americans of this peculiarity. He recommends the vaccinal powder of Reissner of Darmstadt as very serviceable. It is obtained by desiccating the lymph obtained from several pustules, and when employed is mixed with a little glycerine and water. A fragment the size of a pea is sufficient to inoculate fifty persons. The bibliography is classified and complete. The articles on the Vagina and Vulva and on Varicocele seem to be very fully and carefully written, the most recent researches, even those published during the last year, being incorporated in the text. No less praise can be assigned to the article on Variola by MM. F. Balzer and W. Dubreuilh.

The most interesting article in the present volume is, however, the very long one devoted to the Vaso-motor Nerves, by M. Duval, which extends over 160 pages. In this the learned author deals successively with the anatomy and development of the sympathetic nerve, with its general functions and those of the vaso-motor nerves, with the vaso-constrictors and the vaso-dilators, the existence of which he fully admits, giving the demonstration of their existence, the theory of their mode of action, their course, their centres, and their distribution in the bucco-labial region, the liver, the ear, and the limbs. He discusses also vaso-motor reflex actions and the general part played by the vaso-motor acts in local circulation, vascular tonus, and animal heat, as well as in some special functions, such as erection, absorption, exudation, and secretion. He then considers the action of the vaso-motor nerves in pathology. Lastly, he institutes a comparison between the innervation of the vessels and that of the heart. The evidence demonstrating the existence of vaso-dilators is, on the whole, satisfactory. It may be reduced to the following points: First, the experiments of Claude Bernard on the effects of stimulation of the chorda tympani on the secretion of saliva; secondly, the experiments of Cyon on the depressor nerve, showing dilatation of the abdominal vessels; thirdly, those of Vulpian on the glosso-pharyngeal nerve, showing dilatation of the vessels of the posterior part of the tongue; fourthly, those of Eckhard, showing the effects of division and stimulation of the distal extremity of the erector nerves; and, finally, those of Bernard on the auriculo-temporal of the fifth, and of Schiff on the nervus petrosus superficialis minor. The first interpretation given was that of Duchenne, that there were longitudinal and circular fibres in the vessels, the former being under the influence of the vaso-dilator, the latter under that of the vaso-motor nerves. This view was, however, promptly overthrown by the histologists, who showed that there were no longitudinal fibres. The next suggestion was that of Grünhagen, that the dilator fibres caused an active elongation of the muscular fibre cells, but no satisfactory evidence on this point is forthcoming. A third hypothesis has been advanced, to the effect that vaso-dilatation is due to contraction of the venules, but there is strong opposing evidence to this view. Several other explanations have been given, but M. Duval adduces recent evidence to show that the action of the vaso-dilators is not on the muscles of the vessels directly, but on the vaso-constrictors, on which they exert a restraining or inhibitory influence like that of the vagus on the heart.

The last article on the Veins, occupying 270 pages, is quite a treatise in itself, and may be read with advantage by the most experienced surgeon. The pathology of Varices is particularly well given.

A Manual of Animal Vaccination, preceded by Considerations on Vaccination in General. By Dr. E. WARLOMONT. Translated and Edited by ARTHUR J. HARRIES, M.D. London: J. and A. Churchill.

ALL who are desirous of reading Dr. Warlomont's work in the English language will welcome Dr. Harries' translation of the new Manual of Animal Vaccination which Dr. Warlomont states in the preface was written for the English medical world, and from which he has excluded everything that has not directly to do with this special subject. There is little that is new in this edition, and the manual, although interesting, can scarcely lay claim to rank as a scientific work. It is disappointing not to find more exact evidence of the value of different methods of preserving calf lymph. The statement that 500 cases of vaccination with lymph preserved on ivory points met with 499 successes loses much of its value on account of the omission of any reference to the success in each 100 of insertions. But the author credits vaccine emulsion and pomade with possessing an activity nearly approaching that of living vaccine, and maintaining this activity during a mont

Digitized by Google

Later he quotes Dr. Allard, of the African Association, who obtained sixteen vesicles for every 100 insertions of stored calf lymph, a result which is far below the success attained with calf lymph produced in this country. A perusal of the work leads to the conclusion we have before expressed, that the use of stored calf lymph does not produce greater success than the use of stored humanised lymph, and that both should give place where possible to direct arm-to-arm or calf-to-arm vaccination. The translator in an appendix has described his own method. We fully endorse his objection to the vaccination lancet being used for other purposes; but we do not agree with the opinion he apparently holds, that the lancet cannot be thoroughly cleansed with the exercise of reasonable care, nor do we think that its unnecessary sharpness is incapable of remedy.

OUR LIBRARY TABLE.

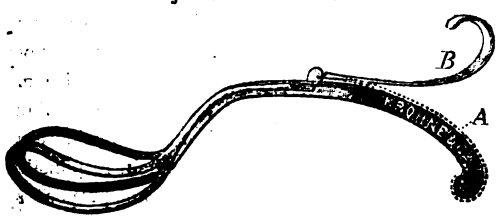
The Asclepiad. No. 9, Vol. 2.—Chilblain circulation is mostly of congenital origin; in many examples it is traceable to premature birth, and in some instances it occurs in those who are of twin birth, but in others the cause of chilblains "runs in families" as if some specific and original taint were at the root of it, like specific disease or struma. This is Dr. Richardson's summary of the pathology of what he aptly calls chilblain circulation. It will be seen that nothing positive is asserted as to the etiology of the affection, which is both difficult to treat and hardly possible of scientific explanation. Many authorities look on the affection as a weakness of the vaso-motor nervous system; others, again, consider that there is an inherent want of vitality in the actual working tissues of the body, and the malady is only met with at those parts farthest from the centre of the circulation because their blood-supply is precarious; but a precarious circulation in distant parts may assuredly be regarded as a predisposing cause of the poor vitality of the tissues. "Temperance and Young Physic" was the address delivered by Dr. Richardson on the occasion of presenting the prize of 100 guineas from the British Medical Temperance Association to Mr. Coryn, student of Charing-cross Hospital; it is an urgent appeal to medical men to prosecute vigorously the war against intemperance. The next chapter is an important physiological one on Pulse-tracings and Cardiac Sounds with the Body Inverted. "As regards the pulse-tracings, the fact that the pulse with the body inverted gives a third or additional wave indicates that the aortic valves, opening back after the arterial recoil has ceased, may allow a column of blood to pass their orifice, under the auricular systole and before the next ventricular systole, with sufficient pressure to cause a second back stroke from arterial tension." There was marked reduplication and accentuation of the second cardiac sound when the body was inverted, and the tracings would seem to show that accentuation and reduplication may be produced by increased vibration of the aortic valves under the influence of augmented pressure. William Cheselden is the subject of the biographical notice, introducing the new era of British surgery, and illustrated by a portrait and an illustration of the house in which his birth took place. Experiments towards the Animal Battery by Compound Synthesis and Micro-electroscopy is a sequel to an essay on an analysis of animal structures by electrical conduction and resistance, in which some particulars were given by Dr. Richardson of an attempt to determine what parts of the animal body are best and worst conductors of electricity. Every organ surrounded by membranes appears to possess condensing powers proportionate to the amount of blood going to the organ; the membranes seem to oppose the dissipation of electrical energy.

The Year-book of Treatment for 1885. A Critical Review for Practitioners of Medicine and Surgery. Cassell and Co. (Limited), London, Paris, New York, and Melbourne.—The second volume of Cassell and Co.'s Year-book of Treatment fully maintains the reputation gained by the first. The list of contributors is almost the same. We miss Dr. Mahomed, Mr. Knowsley Thornton, and Mr. Warrington Haward; but we welcome as new writers for this publication Dr. Sidney P. Phillips and Mr. Walsham. The articles vary in value. Where the writer has freely exercised his own critical faculty the result is more valuable; but the mere reference to a paper or an abstract of it is of little use. As a whole, the book is sure to be popular; it presents a large amount of information in a very compendious form, and as the title of every paper quoted is given in full it forms a very useful book of reference. We have found one or two errors that have escaped the editorial eye. Thus, on p. 127, we read of an incision to be made "in *right median line*, commencing four centimètres below xiphoid cartilage, extending downwards and outwards to three centimètres from cartilage of ninth rib." On p. 138 Mr. Treves is made to state that, in his opinion, "a tight ligature around a damaged nerve would increase rather than diminish its prospects of restoration," when of course the reverse is what he meant. On p. 149 we read of "perpeating" for "perforating." These, however, are errors which appear the more conspicuous from the general excellence of the work. No doubt they will be corrected in later additions.

The Student's Guide to Clinical Medicine and Case-taking. By FRANCIS WARNER, M.D., F.R.C.P. London: J. and A. Churchill. 1885.—We are pleased to see that a second edition of this work has been called for, since its object is the very meritorious one of assisting the clinical clerk to be accurate and ample in his note-taking, and also to arouse his mental faculties and powers of observation. Certain additions have been made in the section upon the nervous system, and a scheme is added for taking notes of children's disease.

Sunshine and Sea. By a COUNTRY DOCTOR. Illustrations by F. T. London: Kegan Paul, Trench, and Co. 1885.—This is an account of a yachting visit to the Channel Islands and the Coast of Brittany, and the Country Doctor, who made up one of the party, brings charm to his story by a style of writing which can only result from a cultured education. He has succeeded in showing that a yachting tour in pleasant company constitutes the best, most healthful, and most enjoyable form of holiday, and we should advise those who have the opportunity to follow the Country Doctor's example and get as much good out of their holiday as he did during his brief one around the neighbouring coast. Before starting, they should read his book, which teems with the bright surroundings of sea, air, and sun, and is attractive by reason of the excellent descriptions of special scenes, and the habits and costumes of the people he met with, and also of the amusing daily incidents attaching to life amongst a merry party on board a yacht. The book itself affords recreation, the more so as it avoids everything that would give it the stamp and monotony of a guide-book.

Whitaker's Almanack. 1886.—We have received the current issue of this really excellent work. It contains an amount of varied information which is not, to our knowledge, to be found in any similar publication, and the editing has this year been, so far as we can judge, done most thoroughly; indeed, we have not been able to detect any inaccuracy in the numerous facts which are briefly summarised in its pages. The most important alteration in the issue for 1886 is the list of members of the new House of Commons. Being the first election under the new Reform Bill it may be regarded as historical, and accordingly the names of all the candidates have been given, with the numbers polled. Under the name of each county is the number of members returned to the unreformed House, and the numbers under



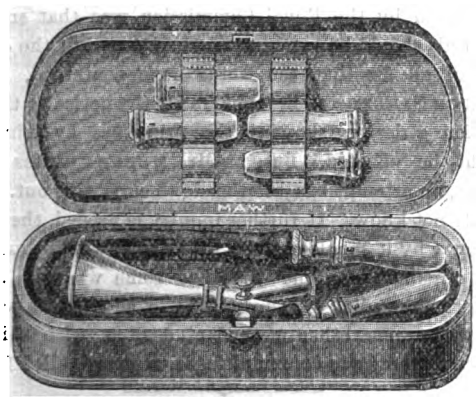
Digitized by Google

each of the three Reform Bills. It is stated that the next issue, that for 1887, is to be entirely remodelled. Whitaker's is the best of our almanacks, and the great success which it has achieved is well deserved.

New Inventions.

NEW AXIS-TRACTION FORCEPS FOR HIGH DELIVERY.

THE forceps, of which I enclose electro, have for their object the simplification of the high delivery and a greater control over axial direction. They have the double curve, after the manner of Dr. Aveling's instruments, and their chief peculiarity attaches itself to the small metallic handle which ships over the wooden handle of the upper blade, and is capable of easy circular rotation to the left or right. When in operation this supplementary handle (B), having its fixed ball-and-socket joint half an inch below the lock on



the anterior surface of the handles, acts as a lever of the first kind as well as a tractor, and by its means a greater axial control of the instrument is effected than by any other mechanism with which I am acquainted, whilst the whole additional contrivance is out of the patient's body and in sight, and all increase of bulk or complicity of the internal portions is avoided. Moreover, the perineal pressure of such instruments as Tarnier's is advantageously relieved. The clever details of the mechanism were worked out by Messrs. Krohne and Sesemann, of Duke-street, whose instruments are ready for inspection.

EDMUND HOLLAND,
Physician to the Hospital for Women.

AN IMPROVED FORM OF STETHOSCOPE.

A VERY pretty stethoscope has been produced by Messrs. Maw, Son, and Thompson, on the principle of the one I described in a contemporary of May 10th, 1884, but differing from it in not being intended to answer a number of different purposes. It is simply a binaural stethoscope with two ear-pieces and two tubes similar to

Steam's, and a metal chest-piece with a Y-shaped junction, so that the whole of the sound is directed into the tubes without having to pass through any cavity in the instrument. At the point of juncture there is a small tube or key which can be closed by the finger. When this is left open the sound is heard as with the ordinary stethoscope and when closed the deeper sounds become audible.

The advantages claimed for this instrument are: 1st. The sound, not having to pass through tubes of different calibre or any cavity in the instrument, is conveyed with greater accuracy, and unaltered in character. 2nd. There is no crossbar or elastic band in the middle, as in the ordinary binaural, so that the hum produced in some by the breath from the nose of the auscultator impinging on an elastic band is avoided. 3rd. By means of the key it acts either as a simple or a binaural stethoscope without moving the instrument. 4th. It is the most portable stethoscope I have seen, and can easily be carried in the waistcoat pocket. It is packed in a neat case with three different-sized pairs of ear-pieces, so as to ensure their fitting any-sized external auditory meatus.

AYDON SMITH.

ANTIPLUVIUM PERFECTUM: WATERPROOF HEALTH GARMENTS.

AN ideally perfect waterproof is, we fear, unattainable. An ingenious attempt has, however, been made in the case of the garments submitted to our notice to combine protection from wet with due ventilation. The "shower-proof" cloaks worn by ladies will resist the rain for a considerable period, if not submitted at the same time to pressure, while they permit the escape of moisture from the surface of the body. Acting on this hint, the makers line this shower-proof material with caoutchouc on that part of the cloth which forms the lower portion of the garment, whilst over the region of the lungs only the shower-proof cloth itself is employed. It is therefore reasonably claimed that excellent ventilation, and what is practically complete exclusion of rain, the garments being quite impervious below the line where any pressure is likely to take place, are secured. The specimens submitted to us have the advantage of being very light, and are, we think, likely to prove a comfortable and useful means of protection against wet and chill. They are manufactured by Messrs. Abbott, Anderson, and Abbott, 70, Watling-street, E.C.

CANCER STATISTICS.

To the Editor of THE LANCET.

SIR,—I wish respectfully to direct attention to a fallacy in Mr. Dunn's paper as given in your issue of the 23rd ult. Mr. Dunn says:—"Taking Gross's statistics as an example, we find that out of 712 women with cancer of the breast 88·22 per cent. were or had been married. Of these, 83·91 per cent. had borne children and 16·09 were sterile, while 11·77 were single. What a remarkable statement is this!" There is nothing very remarkable in this, excepting the unfortunately confusing way of calculating the percentages. But the inference that immediately follows is indeed remarkable! "It is almost certain that if every virgin in England at this moment maintained her *status quo ante* in this respect until the end of her natural life, the female mortality from cancer in the future would be infinitesimal in comparison with present records." Now I trust the virgins of England will not think it necessary to postpone any of their social arrangements on account of this desperate logic; and that "politicians, moralists, and surgeons," so far as concerns this question of marriage and cancer, shall be very comfortable. There is no foundation in the statistical facts—which I may assume to be true—for this remarkable inference. What Mr. Dunn has to show, before his statistics are worth anything, is that the ratio of the number of married women suffering from cancer to all married women is greater than the ratio between the number of single women suffering and all single women. I may put it briefly in this way. Let x = all married women, y = all sterile married women, and z = all single women. Mr. Dunn has to show that $\frac{x}{83\cdot91}$ is greater than $\frac{y}{16\cdot09}$ and greater than $\frac{z}{11\cdot77}$. And even when that is done, and such an approximation of truth attained as can be got from statistics, Mr. Dunn will have to reckon with the complex social and individual influences that determine statistics, and which are the ultimate elements of cause. I have not devoted much attention to this study, but I shall be very much surprised if the exact and correct use of and inference from statistics can show the slightest support of Mr. Dunn's conclusions in this respect.—Your obedient servant,

February 8th, 1886. H. CAMERON GILLIES.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 13, 1886.

IF further proof were needed as to the injurious influence of small-pox hospitals on communities living in their vicinity, it is to be found in the careful report with which Mr. SHIRLEY MURPHY closes his connexion with the vestry of St. Pancras. There is no small-pox hospital actually within the limits of St. Pancras; but the Hampstead and Highgate institutions are sufficiently near to the boundary to enable Mr. MURPHY to form a judgment as to whether any injurious influence, such as has been shown to exist around other small-pox hospitals, had been exerted on the parish for which he formerly acted as medical officer of health. The Hampstead Hospital is fully a quarter of a mile beyond the north-western boundary of St. Pancras, the Highgate Hospital being just outside the north-eastern boundary. As regards the Hampstead Hospital, the circumstances were especially favourable to the investigation made, because the hospital, after having been closed for many years, had again been used for the reception of small-pox patients during 1884.

The results of Mr. MURPHY'S inquiry are shown by means of tables and also by means of a series of excellent diagrams, and in both the practice adopted by Mr. POWER in the case of Fulham, of indicating the amount of disease in quarter-mile rings drawn round the hospitals as centres, has been observed. Taking Hampstead first, it is shown that in the four years 1880, 1881, 1882, and 1883, when that hospital was closed, the houses within the special area of a mile circle round the building were attacked less than those in the rest of the parish, the calculation being based on an examination of the houses invaded per cent. of the total houses; but in 1884, when the hospital again came into use for the reception of small-pox cases, there was "a marked gradation of incidence, the houses in the ring nearest to the hospital suffering more than twice as much as those in the next ring, and more than five times as much as those in the outer ring." Indeed, the houses in the special ring of one mile were attacked at the rate of 2·9 per cent., whereas in the rest of the parish they only suffered to the extent of 0·9 per cent. As regards the Highgate Hospital, the conditions were, subject to certain local influences, very similar, and in 1884 the incidence of the disease on the area within a quarter of a mile of the hospital reached 7·70 houses invaded per cent. of total houses, as opposed to 1·3 per cent. in the remainder of the parish. The diagrams we refer to are extremely valuable. They show how in 1880, a non-epidemic year, the comparatively few houses attacked in St. Pancras were distributed all but uniformly throughout the parish. In 1881 there was an epidemic, Hampstead Hospital being closed, and Highgate being open. During this year small-pox is shown to be generally diffused throughout the parish, with some special aggregation in some of the more densely peopled districts; but whilst there is certainly no special incidence of the disease in the immediate vicinity of Hampstead Hospital, there is quite a mass of red dots, showing how severely the houses in the immediate neighbourhood of the Highgate Hospital were attacked. The years 1882 and 1883—non-epidemic years—resemble 1881 in so far as the distribution of the few cases of small-pox which occurred is concerned, except that in 1883 a slight outbreak occurred near Highgate Hospital. Then comes the crucial year, when both Hampstead and Highgate hospitals were in full working, and it needs but a single glance at the map for that year to enable the most uneducated observer to see how great is the influence for harm which those two institutions exerted upon the houses in their neighbourhood. A great mass of red marks around Hampstead go to show that, in the one-quarter to a half mile circle, 6·7 per cent. of houses were attacked; 3·1 from one-half to three-quarters of a mile; 1·3 from three-quarters to one mile; and only 0·9 in the remainder of the parish. The result would doubtless have been still more striking had Mr. MURPHY'S district included the area within a quarter of a mile radius of the hospital.

So far we have said nothing as to the precise means by which this grave injury has been brought about. Mr. MURPHY'S inquiry did not enable him to decide how far an aerial diffusion of infection could be held responsible for it, and under these circumstances we do not propose again to discuss this question in detail. But the matter is none the ess grave if we abandon all notion of an aerial distribution. Quite the contrary. As Mr. MURPHY points out, the Metropolitan Asylums Board have honestly striven to give effect to nearly all the recommendations of the Royal Commission on Fever and Small-pox Hospitals. The number of acute cases at each hospital is strictly limited; precautions are taken with regard to the staff and visitors such as were never before thought necessary; and the ambulance service, in its strictness as to details, is practically perfect. And yet the mischief goes on just as it always has done, and it probably will continue to do so until the true cause of this diffusion is frankly admitted. Mr. POWER'S observations go to show that the cause is an aerial one; but whilst all sorts of expedients, excellent in themselves, are being resorted to, nothing is being done to check the diffusion by air. An essential recommendation laid down by the Royal Commission was that small-pox hospitals should be so constructed as to permit the destruction of all air that the wards have contained, and Dr. BURDON SANDERSON brought under the notice of the Commission a design showing the principles by which this might be effected. But, as Mr. MURPHY states in his report, no attempt has been made to carry this out. Why? We do not know. If further inquiry is needed, there is no reason why it should not be made forthwith. But under any circumstances the time has come when it is clear that the remedial measures hitherto adopted have failed, and when some other method of dealing with this grave source of danger to communities is urgently called for.

PROFESSOR V. PETTENKOFER is justly regarded as one of the highest authorities upon sanitation and epidemiology. He may, in truth, be said to have been the pioneer in Germany of scientific hygiene, just as one may claim for PARKES a similar position in this country. The medical profession associates Professor V. PETTENKOFER mainly with his

Digitized by Google

studies upon cholera and typhoid fever, for he represents the anti-contagionist school, and his subsoil-water theories have long been before the world. Any contribution that he makes to the subject is sure to receive attention; so that the substance of a recent address given by him upon the relationship between Bacteriology and Epidemiology (to be found in the *Münchener Med. Wochensch.*, 1886, Nos. 3 and 4) is worth perusal. It is remarkable in many ways, but especially for the candour and justice with which the newer doctrines are treated. There is much truth in his opening remarks upon the glamour which has been developed by the fascinating pursuit of bacteriology, so that it is not surprising that the assertion has been made that this study has for the first time given epidemiology a scientific basis. It has undoubtedly, he admits, increased the means of diagnosis, but he contends that it has done little to advance the cause of prophylaxis or treatment beyond the position previously attained. What, he asks, has the discovery of the tubercular bacillus done to reduce the mortality from phthisis? or in what respect has the detection of the typhoid bacillus aided in advancing the sanitary measures and lines of treatment which have already effected so notable a reduction in the mortality from typhoid fever? Indeed, many real advances in the treatment of diseases now proved or suspected to be due to the invasion of micro-organisms have been made almost empirically, or, at any rate, without any reference to the existence of specific germs; and once more he reiterates his opinion that the concentration of view upon the single factor of bacterial origin, to the neglect of the other factors of telluric and seasonal conditions, is responsible for much erroneous doctrine. Even as regards disinfection, bacteriology has added little to the principles previously established by epidemiology, or by the practical acumen of a LISTER, whose system was based upon the general doctrine of fermentation and putrefaction through the intervention of living organisms, and not upon a direct demonstration of the effects of certain antiseptics upon special forms of bacteria. It is true that subsequent knowledge had demonstrated more exactly the germicidal properties of antiseptics, but the principles of antiseptic surgery were established without such direct aid from bacteriology; indeed, the pursuit of the latter was doubtless largely impelled by the successes achieved by the former. On the other hand, the discovery of the prophylactic power of inoculation by the attenuated virus, as demonstrated by PASTEUR in the case of anthrax, must be admitted as the outcome of bacteriological research, throwing light upon the *modus operandi* of vaccination; yet the most recent work of PASTEUR upon hydrophobia has been accomplished without any demonstration of the actual morbific agent in rabies. That a knowledge of the specific organism of any infectious disease does not often explain the cause of an epidemic is illustrated in the case of anthrax, which can so readily be transmitted by inoculation; whereas the spontaneous disease may at one time attack only one animal in a herd, at another strike down several almost simultaneously and give rise to a widespread epizootic. The fact of a transmission by inoculation, or, in other words, the experimental test of infectivity, cannot, then, explain satisfactorily the origin and spread of epidemics. This point has been lately further illustrated by the successful inoculations by MARCHIAFAVA, CELLI, and others in the case of malarial fever. These experiments showed conclusively that blood taken from a patient suffering from intermittent fever could, when inoculated, transmit the disease; but no one would pretend that this proved that the malarial virus is habitually transmitted by individual infection. May we not, then, legitimately conclude from this that, although tubercle can be undoubtedly transmitted by direct inoculation, it is not thereby *proved* to be a contagious disease?

Professor v. PETTENKOFER continues his argument by referring to the long-established division of infective diseases into contagious and miasmatic, some diseases occupying an intermediate (because undetermined) position between these two classes. Bacteriology is breaking down these artificial distinctions—which, by the way, Professor v. PETTENKOFER would prefer to style "entogenous" and "ectogenous," according as the virus is transmitted direct from the sick to the healthy, or results from a micro-organism developing apart from but in the vicinity of the infected patient. It is important, therefore, to determine whether an epidemic spreads entogenously or ectogenously. Many think that if a specific fungus is found in the patient, and especially if the disease can by its means be transmitted experimentally to the lower animals, that is a proof of its entogenous character, and that the disease can be spread by the patient or his excretions. This is the point which Professor v. PETTENKOFER criticises, taking as examples the important diseases typhoid fever and cholera. No one would rank cholera among the purely contagious diseases, as syphilis and small-pox; but the general doctrine is that it is contagio-miasmatic. We all know that, as regards cholera, experts are divided into two camps—the contagionists and the anti-contagionists; yet it is noteworthy that at the conference held last year in Rome, where the former were in a majority, there was a unanimous declaration to the effect that the safest prophylaxis against cholera epidemics lay in local sanitary measures, with the proviso, however, in favour of the enforcement of measures directed especially against contagion, such as quarantine, isolation, disinfection, and the like. Professor v. PETTENKOFER is, however, fully convinced that epidemics of cholera are solely ectogenous in their origin, and that the disease is no more contagious than is malarial fever. Not that cholera arises like malaria, for, although endemic in some parts of India, it can be conveyed elswhere; not, indeed, in the way urged by the contagionist school, otherwise Europe, and especially Egypt, would never be free from its invasion, so close is the intercourse between them and the home of cholera. Even in India itself cholera is limited to certain localities, and all epidemiological research goes to prove that there is a great difference in the susceptibility of localities to become infected, and even a varying susceptibility in one place. Again, he shows that the imported cholera germ will remain latent for a time as shown in the recent epidemics, where Egypt was attacked in 1883, infecting Toulon, Marseilles, and Naples, where the disease was not manifested till 1884; Spain was infected from the South of France in 1884, but the great epidemic did not arise till 1885, and even now the coming year may show that other parts of Europe received the infection last year from Spain. No sanitary cordons or quarantine, no isolation of the sick or disinfection, could

Digitized by Google

avail to prevent epidemics of a disease which spreads so mysteriously; and experience shows that all such measures are invariably adopted too late. Moreover, PETTENKOFER claims that the few cases advanced by the contagionist school in support of their doctrine are capable of an ectogenous explanation, although such authorities as GRIESINGER and VIRCHOW have been compelled by such facts to admit that occasionally cholera is communicable, an admission which would lay the burden of proof upon the bacteriologist to show how and under what conditions the germs can be at one time transmitted directly from individual to individual. That it cannot, as a rule, infect, is shown by the immunity enjoyed by the attendants on the sick. The fact that cholera appears in a locality after the introduction of a case of the disease, whereas healthy immigrants coming from an infected place do not apparently convey the germs, lends apparent support to the contagionist doctrine; but Professor PETTENKOFER sees no difficulty in believing that a cholera patient must of necessity have been in more intimate contact with the virus, and that he contaminates the locality and not the inhabitants directly. Why is it, if the disease be contagious, that once it is introduced it does not always spread? It is, he thinks, because the conditions of the locality and the seasonal conditions are such as do not permit of the development of the poison. An outbreak of cholera on board ship can almost invariably be traced to importation of the poison from an infected port, but there is no proof that the disease spreads by direct contagion from the individual who introduced the poison. So also with limited outbreaks, house epidemics, &c., the explanation given by the Professor is, he holds, more reasonable than that of the contagionist, who would have to show why so many exceptions occurred under conditions apparently so favourable for the spread of a contagious malady.

Nor does Professor v. PETTENKOFER limit the scope of his criticism to those who assert that such a disease as cholera is directly transmissible from one human being to another. He is equally opposed to those who hold that drinking-water may be contaminated by the choleraic discharge, and the disease spread in this way. His position is that the water would not be a medium for the conveyance of the cholera virus did not the nature of the locality also happen to be favourable for its development. In this respect, he remarks, there is a close analogy between cholera and typhoid fever, which is so universally believed to be propagated through the medium of water. We fail, indeed, to follow Professor v. PETTENKOFER here in the face of accumulated facts pointing to the transference of the typhoid poison from individual to individual by means of this and other articles of food. Nor does he touch upon the subject of milk epidemics, which surely bring a great body of evidence in support of the typhoid virus being so transmissible. He contents himself with disproving that the Wiesbaden epidemic of 1885 had anything to do with contamination of water; and it seemed to be proved to depend on defective drainage. He holds it to be the duty of bacteriologists to extend their field of inquiry; he admits their facts so far as they go, but thinks their conclusions are erroneous from the limited range they permit themselves. Practical measures of hygiene can be framed only when all the circumstances of epidemic disease are taken into account. The discovery of the specific pathogenic organism can do little more than subserve diagnosis and explain the phenomena of the disease; the full etiological explanation, with the resulting hints towards prophylaxis and treatment, requires a research into the whole environment of the micro-organism and the conditions that influence its growth and development. He welcomes the new discoveries made by the bacteriologists; but he cannot admit that they have in any respect undermined the well-established facts of epidemiology; to harmonise these two great sources of inquiry must be the task of the future, if we are to reap the full benefit of all that is being done to advance our knowledge of the nature of disease.

THE regrettable and humiliating occurrences of the last few days in London, which, through the culpable want of foresight and energy of the Home Office or police authorities, has been practically handed over to the mercies of the turbulent classes, may well form a subject of profitable study to those who are professionally concerned with the working of that important *function* which we call mind. The observation of mind working in a mob is an exercise full of interest and instruction. Mob-mind may be defined as the outcome of all the actions and interactions of individual minds upon each other when brought into intellectual contact by the simple fact of concourse. This is something quite different from public opinion. When a number of persons thinking on the same lines in reference to any question are thrown together, they bring with them special forces of construction and are prepared to form bonds of cohesion. Their several purposes are ready to merge in a common purpose. No doubt there is something of this pre-existing affinity at work in the mental constitution of every mob. If the component parts of a crowd were not in some measure qualified to act together they could not voluntarily assemble, or, being thrown together, would not coalesce. Nevertheless, there is a different force, or, more correctly speaking, there are different forces, at work in the constitution of a mob properly so called. The term "mob" implies heterogeneity on the part of its elements, and excludes the idea of organisation or the existence of a common purpose. It is not therefore possible that a mob in its true sense should possess a mind composed, as it were, of the fused elements of a multitude of minds, in respect to the higher forms of cerebration. The mental activities of a mob are limited to passion, impulse, and imitation; in fact, to the lower range of mind-energies. Given a multitude of impressionable persons, it is by no means necessary that they should have formed opinions on any special subject to make them ready to act together either under the influence of passion, impulse, or imitation. It is, on the contrary, possible, and even probable that they will act in direct antagonism to their principles—the principles that govern their several lives — while they are under the influence of passion, impulse, or imitation. It is very curious to observe how this works. There is a subtle but mighty influence exerted by numbers, which stirs the passions, and impels a man to imitate those around him. If one man become excited, others will take the infection, and the spirit of turmoil rises and spreads through the crowd without any

Digitized by Google

necessary sympathy between the individuals acting together in respect to a common object. If one man looks in a particular direction, others look, they know not why. If one man runs, the many run without reason; and if one member of a crowd resort to violence, others follow suit though no special purpose animates them. There is an evolution of something which for the time takes the place of a common thought or motive, but which is actually nothing more than a stirring of the lower mental energies, and not in any true sense entitled to the dignity of being described as intellectual, and yet, looking to its capabilities when once evolved, is fairly describable by no less a term than mob-mind. A mob stirred by this influence quickly grows to be a party with all the making of an organised body. In the brief space of a time that can be measured only by its incidents, a crowd of heterogeneous particles of humanity may be so welded together by their deeds that from the instant when this union takes place it shall constitute a coherent mass. This is how revolutionary mobs are made. A crowd assembles; one-half of the persons present probably are conscious of nothing more potent in the nature of motive than curiosity. They do not even hear the speaker addressing the gathering; they are simply impressed by sounds, sights, and the influence of numbers. Presently they are stirred by some impulse arising out of, or appertaining to, passion; they imitate, unconsciously it may well be, the acts of those around them, and, without thinking why, they take part in proceedings they do not even understand. It is even possible that they may take weapons thrust into their hands or missiles placed at their disposal, and use them in the perpetration of deeds of lawless violence, without being aware of the purpose which they are ostensibly striving to carry into effect. Nearly all riots and revolutions begin in this way. In a few hours, however, it becomes necessary to justify to the consciousness the act in which the creature of impulse has been engaged, and reason — the perverted faculty of a mob-mind—comes into play. It follows from this view of the growth of mob-mind, that those are the real offenders against the public peace who permit mobs to assemble and supply them with opportunities of doing deeds which give birth to malignant purposes. When the police are allowed to stand idly by and permit the assembling of large crowds of impressionable persons, when they are instructed not to interfere with "horseplay" which is the prelude to crime, the authorities responsible for this blind policy are assisting at the birth of an organic revolution. We do not hesitate to say that nothing which can now be accomplished will atone for the apathy of the Home Office and of the authorities at Scotland-yard last Monday. A mob has been allowed to constitute itself, and though for the moment its component members may be kept apart, the active germ of a revolution has been ushered into existence. A mob-mind has been constituted, and has not simply formed a purpose, but been permitted to indulge in triumph over its achievements. For more than an hour before the smallest act of violence commenced on Monday, there were unmistakable evidences of an impending riot within a stone's throw of Scotland-yard, the central office of the police. Either no detective had the wit to convey the intelligence to head-quarters or the authorities there were too supine to act. Fifty policemen drawn across the entrance to Pall Mall would have put an end once for all to the riot at its outset. No such precaution was taken. For two hours the West-end was left to the mercy of the mob, and, stranger still, the riot achieved, the rioters were actually allowed to hold a meeting of triumph at the foot of the Achilles statue. No such crime of omission as was committed by the Home Office and the chiefs of the police on Monday has been committed by any public authority since the days of the Gordon riots. We trust that when Parliament meets once more, the urgent questions arising out of these events will be raised, and that they will not be allowed to remain unanswered. A great opportunity for the study of mob-mind has been most needlessly created, and there is only too much reason to fear that it will not be long before the malignant mental organism, to which administrative folly has given birth, will again make its presence felt in our midst, gathering additional weight and influence each moment it is permitted to exist. The prosecutions in progress, though needful in their way, are like measures for locking the stable-door after the steed is stolen. The deed has been done, and the full issue is not yet reached.

DR. PILCHER, in a paper read before the New York Surgical Society, has discussed in an interesting manner what is the right line of practice to pursue when the main vein of a limb is suddenly and permanently occluded, especially whether simultaneous ligature of the companion artery obviates the risk of gangrene. The proposition is twofold. What ill effects are likely to follow the sudden and complete occlusion of a main vein? And then, if ill effects follow, how are they best dealt with? There are few more striking pathological facts than the remarkable way in which the *gradual* occlusion of veins, as by the pressure of morbid growths, is compensated for. Even one or other vena cava may be slowly obliterated with strikingly little interference with the circulation in the parts affected. In such cases anastomosing veins have time to enlarge and to furnish sufficient channels for the returning blood. Far different is it where the obstruction is *sudden*, as from a wound, where the anastomosing veins have not been previously enlarged; and it is therefore not safe to argue from the former case to the latter. BRAUNE and others have attempted to elucidate the problem by experiments on the cadaver. The main vein of a limb has been tied, and the force necessary to return fluid from a distal venule to the heart has been measured, and from this it has been questioned whether the normal forces carrying on the venous circulation are or are not sufficient to overcome the obstacle. Such experiments are interesting, and to a certain extent useful, but the results so obtained must be applied with extreme caution to the living body. The vessels have other than physical properties, and the vital contractions and relaxations of arteries and veins respectively may affect the case very materially. The one special danger to be feared from the sudden obliteration of the main vein of a limb is gangrene from venous stasis, owing to the inability of the vein radicles to empty themselves. Experience has shown that this is by no means sure to result even from closure of the common femoral vein. LANGENBECK has recommended that in any such case the main artery should be ligatured at once, as in that

Digitized by Google

way a smaller quantity of blood is carried to the part beyond, and less stress is thrown upon the overcharged veins. Experience, however, does not support this view. The ligature of both vessels has been successful in certain cases, but on the whole the mortality, and the frequency with which gangrene has occurred, have been greatly increased by this practice. In no situation has this been more clearly demonstrated than in the neck, where the ill effects of ligature of the internal jugular vein are considerably exaggerated by simultaneous ligature of the artery. Nor is this result to be wondered at. Ligature of the main artery of a part is attended with two results which are unfavourable to the venous circulation. In the first place, the local anæmia causes a general dilatation of the arterioles, with compression of their attendant venules; and, in the second place, the force of the heart is dissipated in propelling the blood through the many narrow anastomosing arteries. In the life-history of aneurysm two facts are often noticed which throw light upon this matter. The first is the marked effect of the pressure of an aneurysmal tumour upon a neighbouring vein, the direct influence of the venous obstruction being supplemented by the impediment to the arterial circulation caused by the presence of the aneuryam and the diseased state of the arteries beyond it. And it is just in such cases that the danger of gangrene after the Hunterian operation is greatest. When the force with which the blood is propelled into the limb is cut off by ligature of the main artery, the return of blood from the parts beyond becomes impossible from the diminished *vis a tergo*. It is therefore a grave question whether and how far an obstructed venous circulation is aided by such a diminution of the vigour of the circulation as is necessarily caused by the ligature of the main artery of a part. At any rate our present experience is opposed to the line of practice suggested by LANGENBECK.

MR. HUTCHINSON raised a most important question when he proposed to the Council of the College of Surgeons to extend the basis on which the Fellowship is bestowed. We do not profess to know exactly the lines on which he will proceed, but it seems to be no secret that the proposal is that fifty Members of the College are to be raised to the rank of Fellow, either without any, or after a very modified, examination. We confess to a feeling of great disappointment at this announcement. In the first place, the proposal does not come from the Council *proprio motu;* then, it is not a desire to mark special merit or conspicuous success; it is not even to reward those who have done the College good service. On the contrary, it is a sort of olive branch, and too obviously an attempt to pacify a growing determination among the Members of the College to exercise rights and privileges which pertain to membership among all other corporate bodies, without either cavil or question, by offering to a few of their number the bribe of an empty Fellowship. The carrying out of such a proposal will slowly increase the ranks of the Fellows, but it will lower the status of the Fellowship; on the other hand, the Members will lose, not numbers only, but the weight and authority which the seniors among them carry, and in this way the status of the Membership will also be lowered. The result will prove disastrous, and will be a retrogressive step in every sense of the word Moreover, supposing that fifty men could be found worthy of the honour—from a purely negative standpoint we have no sort of doubt that for the first two or three, or even more years, very suitable men *could* be found,—the injustice of excluding about *eleven-twelfths* of the body corporate from all participation in College management will be as glaring as ever. It is one which can never be atoned for by anything short of the full abrogation of the principle, and it were to be wished that the Council could be brought to see this. It is futile on their part to longer pretend to be blind to the extent and purpose of the present outcry among the Members of the College, and individual members of the Council who bring forward proposals to deal partially with the subject only the more prominently mark their own prejudices in matters on which a more liberal and enlightened policy might fairly be expected from them.

We have at various times pleaded for the official recognition by the Council that the Members of the College, as part of a corporate scientific body, are fit to exercise corporate rights—that is, to vote and to take part in its management. Their exclusion is anomalous as well as unjust; it is a marked slur cast upon the Members of the College by those who ought to be the first to claim respect for them. To send these men out into the world as practitioners, and yet to say we will have nothing more to do with you, is derogatory to the dignity both of the College itself and its Members. We have never ceased to urge the desirability of raising the standard of the Membership to the highest reasonable level, the need for wider culture, improvement in the curriculum, and a more thorough and prolonged training; and we gladly acknowledge the progress which has been made in the last few years. It is largely due to these influences that we now see the present reform movement surging through the profession. A feeling that injustice was being done to them has long existed in the minds of the Members; but the want of an organisation as a mouthpiece, not less than the occupation they follow, has hitherto prevented them from expressing their feelings. Increasing numbers of more and more highly educated men, and the steady growth of the principle of direct and responsible representation, are, however, at last making themselves felt. Under such circumstances we doubly regret the present proposal to widen the basis on which the Fellowship is bestowed. The Association of Fellows, which has so unceasingly expounded the political aspects of this present crisis, has placed the Fellows and Members alike under a further obligation by pledging itself to resist any attempt to degrade the academical status of the Fellowship, and we have reason to think that the best of the Members will be hardly less unanimous in declining to accept such borrowed plumes as it is proposed to offer them.

On many grounds, therefore, it is most undesirable to widen the basis of the Fellowship. On the other hand, are there not good reasons why, if any alterations be made, it should be further limited? When justice has been done to the Members, and the examinations for the Membership have become more and more what they should be, the diploma of Membership will be highly prized, and even more sought after than at present. The College of Surgeons should do everything they can to raise their Membership,

Digitized by Google

and its possession should carry with it any privileges the College itself has to offer. The Fellowship, on the other hand, should approximate more and more to the nature of an academical honour—a wranglership, in fact; it ought not to carry exclusive privileges at the College, where all Members should be on an equal footing till raised above the ordinary level by the voice of their fellow-Members. In the hospitals and schools of medicine, however, every possible privilege may be given to it, in order to induce as many as possible to more effectually "promote and encourage the study and practice of the art and science of surgery," and in order to bestow compensating advantages on those who give up time to this purpose. We hope the Council will decline to accept Mr. HUTCHINSON'S proposal; and we shall regard such an issue as the harbinger of a policy more in accord with the requirements of the times. It would be humiliating to the Council to apply for and be refused the alterations in the Charters on which they decided upwards of a year ago; and yet, should they be rash enough to apply to the present Government in face of the Members' petition now in course of signature, we cannot for a moment doubt the result. The Council ought seriously to consider their position; they have only two courses open to them—either to resign as no longer having the confidence of their constituents, or to initiate with good grace such changes as will re-secure it.

Annotations.

"Ne quid nimis."

FROM BAGSHOT PARK TO WINDSOR CASTLE.

THE Duchess of Connaught is shortly, it is stated, to transfer her abode from Bagshot Park to Windsor Castle to undergo her confinement. It will be remembered that on a former occasion when Her Royal Highness was confined at Bagshot Park symptoms of a septic nature presented themselves, to the alarm of the medical attendants and anxiety of the Royal Family. At considerable risk the Duchess was removed a few days after her confinement from Bagshot Park to Windsor Castle. The lesser of two evils had to be resorted to. If the Duchess had been permitted to remain in the newly-erected residence in Bagshot Park there would have been a continued exposure to the septic poison, which had already excited very grave symptoms. On the other hand, there was some risk in the removal from Bagshot to Windsor so soon after a confinement. But this was the lesser evil, and was wisely decided upon. It was subsequently found that the drains of the house in Bagshot Park were defective. These, however, have been rectified, so that this source of danger is removed; yet there are still good reasons why the Duchess should be advised not to undergo another confinement in Bagshot Park, and that preference should be given to Windsor. The deaths from childbirth and childbed fever in the registration district comprising Bagshot Park are double the death-rate in the Windsor district, notwithstanding that the former is a thinly populated rural district, while the latter is a more thickly populated urban district. If the registration district comprising Bagshot Park be compared as regards death from childbirth and puerperal fever with that of Stepney, Mile-end, or Poplar, or, indeed, most of the poorer districts of London, it will be found to be in excess of these, and therefore fraught with more danger to a parturient woman. There must, therefore, be something beyond defective house-drains to give rise to this high death-rate from childbirth and puerperal fever in a country district in the midst of moor and heather, and in the very centre of the wide range of sandy soil known as the Bagshot Sands. The district of the Bagshot Sands, as we have on former occasions pointed out, consists on the higher ground of light porous sand, which drains into the valleys of retentive clay, marsh, and bog. These low-lying damp districts are insanitary, and specially favourable to septic diseases affecting parturient women—diphtheria, malaria, and what is popularly known among the poorer inhabitants as aguish rheumatism. Residents on the low-lying marsh-lands of the Bagshot Sands are liable to one and all of these. To drain these marshes would give work to the unemployed and effect a great sanitary improvement. Much of these sandy wastes and marshes belong to the Government, and might fairly be dealt with at the cost of the nation.

WORK FOR THE UNEMPLOYED.

VERY extensive tracts of country belong to the Government, and produce very large returns under the name of "Woods, Forests, and Land Revenues," which are managed by a department of the Government known as the "Woods and Forests" at a cost of somewhere about £22,000 a year. There are several commissioners, who receive £1200 a year; a solicitor, £1500 a year; clerks and other officers, £900 a year. Such salaries should represent service on very large monetary returns, and so it will be found to be. At the end of one financial year there was a cash and stock balance amounting to more than £600,000 at the disposal of this department for permanent improvements. The extensive tract of Government property stretching from Windsor Park to Aldershot admits of very great permanent improvement. The larger portion of it is unreclaimed. To trench some portions and plant with Scotch and larch would bring some return for expenditure. To drain the low-lying marsh districts around Bagshot Park, Wellington College, the Royal Military Colleges, and the Camp at Aldershot would effect a great sanitary improvement, even if confined to those portions of these districts which actually belong to the Government. Here, then, is abundance of work for the unemployed, and £600,000 available in one department of the Government to pay for it, with the prospect of a real permanent improvement to Government property and increased sanitation where it is much needed. A pickaxe and a spade are the only tools needed for the work. Sir Robert Rawlinson could devise a scheme for the Government in less than twenty-four hours, for he has already had a large experience in designing work of this kind. Ten thousand workmen might be well employed at task work—that is, remunerated in proportion to the work they do. They could be divided into sets, according to the lodging accommodation, with one ganger to every hundred men. The improvements in the Royal forests might be carried out on the lines commenced by the late Prince Consort nearly fifty years ago, the good effect of which is palpable enough in Windsor Park and the Royal forest around, and consisted mainly of trenching, draining, and planting, each of which is in the direction of an improved sanitation much needed.

AIR EMBOLISM.

AN experimental and clinical study of air embolism carried out by Dr. N. Senn of Milwaukee, Wisconsin, has led him to the following important results. The presence of adventitious air in the vascular system during life gives rise to air embolism. Each air embolism constitutes a mechanical source of partial or complete obstruction to the flow of blood in the vessel in which it is located. Aspiration during the inspiratory movements of the chest is the

Digitized by Google

direct or exciting cause of ingress of air into a wounded vein or sinus. Elevation of the head is the sole predisposing cause of the entrance of air in wounds of the superior longitudinal sinus. In veins the predisposing causes consist in elevation of the part wounded, and in pathological or anatomical conditions which prevent the collapse of the wounded vein. Insufflation of a fatal quantity of air into a vein produces death by mechanical over-distension of the right ventricle of the heart with paralysis in diastole, and by asphyxia from obstruction to the pulmonary circulation consequent upon embolism of the pulmonary artery. Insufflation of the same quantity of air into arteries is less dangerous than when introduced into veins. When death is produced in this manner it results from acute cerebral ischæmia, secondary venous air embolism, or intense collateral engorgement of the vessels of the brain and spinal cord. Air injected into arteries is readily forced through the systemic capillaries into the venous circulation and the right side of the heart by powerful contractions of the left ventricle. Air embolism of the pulmonary artery is relieved in a comparatively short period provided the contractions of the right ventricle continue unimpaired for a sufficient length of time. The prophylactic treatment should consist in proximal double compression or ligation of the vein that is endangered by an operation. The indirect treatment should have for its objects the prevention of admission of air, the administration of cardiac stimulants, and venesection. The direct or operative treatment should be by puncture and aspiration of the right ventricle; catheterisation, and aspiration of the right auricle. These last recommendations no doubt have the aspect of severe measures, but in some cases death is imminent, and desperate means become justifiable. Dr. Senn asserts that the results obtained by experiments on animals warrant the adoption of the operative treatment of air embolism in clinical practice. The chances of increasing the mischief by catheterisation of the right auricle must not, however, be overlooked.

PUBLIC HEALTH IMPROVEMENT IN ENGLAND.

THE death-rate in England and Wales in 1885 again fell to 19·0 per 1000 of the estimated population, and, excepting only the year 1881, when it was 18·9, was lower than in any previous year since civil registration came into operation in 1837. The Registrar-General's Quarterly Return, relating to the last three months of 1885, calls attention to the fact that the death-rate in each of the five years 1881-85 was considerably lower than the rate recorded in any year prior to 1881. The mean rate in the first half of the current decennium (1881-90) did not exceed 19·3 per 1000, showing a further decline from 20·8, the mean rate in the preceding five years 1876-80; whereas, in the preceding forty years of civil registration the mean annual death-rate was 22·3, and the lowest rate in any quinquennium was 21·4 in 1841-45. This marked reduction in the English death-rate has now been maintained for ten years, and has been much greater in the second than in the first half of that period. It cannot, in the interest of further health progress, be too constantly borne in mind that the commencement of this period of reduced death-rate was coincident with the coming into full operation of the Public Health Acts of 1872 and 1875. The effect of this reduced death-rate upon the numbers and longevity of the English people is phenomenal. The Registrar-General points out that the reduction in the death-rate in the last five years implies that "more than 281,000 persons in England and Wales survived that period, whose deaths would have been recorded had the mean rate of mortality been equal to that prevailing in the ten years 1871-80," in the latter half of which period the improvement in the public health had already set in. With regard to the increased longevity of the population, Mr. Noel Humphreys, in a paper read before the Statistical Society in 1883, showed that the effect of a reduction in the mean death-rate from 22·5 in 1838-54 to 20·8 in 1876-80 would be to add two years to the mean duration of life of every male, and three years and a half to that of every female born. The further reduction of the death-rate in the last five years to 19·3 implies a still greater additional lengthening of the mean duration of life in England.

THE METROPOLITAN BOARD OF WORKS ON THE VENTILATION OF SEWERS.

THE competency of the Metropolitan Board of Works to deal with the question of the ventilation of sewers, and the prospect that success will attend the efforts of that body, may be inferred from many singularly instructive passages in the Report of its Special Purposes and Sanitary Committee. For example take the following:—"When the temperature of the air of the sewer is lower than that of the external atmosphere, and no other influence is at work, the colder atmosphere of the sewer, being heavier than the external air, remains in the sewer; but when the outer air becomes colder, and consequently heavier, than the air in the sewer, it presses down through some of the openings to the sewer and drives out the warmer and lighter air through the other openings. This is noticeably the case on cool evenings in the hot dry season, at which time the nuisance from sewer ventilation is probably at the worst. It is therefore necessary to provide in sewer, as in all other ventilation, inlets for the cold air as well as outlets for the warm air." The fallacy of this extraordinary statement must be apparent if only we reflect that sewer gas is drawn into houses even when the temperature of the house is only a little above that of the external atmosphere, and of course much higher than that of the sewer. As a matter of fact, the air in the sewer does not fail to rise whenever and wherever the atmosphere above it is warmer. The assumption of the authors of this report as to the behaviour of sewer gas is based entirely on theory, and has no better foundation than the school aphorism that colder and more condensed gases underlie lighter ones, an aphorism which is perfectly well known by practical men to be untrue in actual working, the interchange and diffusion of gases being determined by other causes besides those of mere temperature. The Committee go on to say: "During the autumn and winter months the average temperature of the air of the sewers is warmer than the external temperature by about seven degrees; in spring the temperature is about equal, and in summer the external day temperature averages over three degrees warmer than that of sewers." So that if the law on which the reporters rely were applicable, sewer gases ought to rise out of the warm sewers into the cold external atmosphere, particularly during the autumn and winter, while in the spring there should be little change of place, and in summer there should be no ascent of sewer gas at all! "At night," says the Committee, "the temperature of the sewers at all times of the year is usually higher than the temperature of the external air," and the general conclusion drawn is "that throughout the greater part of the year the natural law, by which the heavier colder air forces out by its greater weight the warm air of the sewer, is in operation, and if proper facilities are given, that law will ventilate the sewer." The Sanitary Committee, therefore, clearly thinks that it is under conditions in which the temperature of the external air is lower than that of the sewers sewer gas escapes. It is therefore preposterous for anyone to speak of smells from sewer gas in summer. It is impossible that there can be any smell under such conditions, when the temperature of the external air is three degrees higher than that of the

Digitized by Google

sewers. No wonder the sanitary inspectors are so curt when in our ignorance of "natural law" we complain of effluvia from the sewers in summer. The Committee is good enough to admit that temperature is not everything in sewer ventilation. Something must be conceded to the effect of throwing "hot water and other liquids" into the sewers. Materfamilias must look to it that her servants do not poison the whole neighbourhood by allowing a little hot water to escape into the house drains and travel thence into the sewer. We should very much like to know how much hot water is cast into the sewers of the metropolis in twenty-four hours, and to what extent it suffices to raise the temperature of their contents, even locally. "The force and direction of the wind" have doubtless some effect on ventilation, and we are glad to find the Sanitary Committee recognise their agency; but they seem to think that in some mysterious way the sewer-gas is induced by the wind to flow to higher levels, like that of Hampstead. The need for this hypothesis of the action of the wind or a back current arises from the "natural law" to which we have already alluded. Firmly convinced that sewer-gas must needs be too heavy to rise unless artificially heated in some way, the Sanitary Committee is unable to understand what everyone else understands—namely, how and why it happens that the gases in low-level sewers and drains rise to those of higher level, and by way of explanation it imports a theory of wind-action. It would be wearisome to follow the schoolboy speculations of this Report further. No real reform can be expected whilst such ignorance in high places is allowed, not only to exist, but to prevail.

DOUBLE BRONCHOCELE SUCCESSFULLY EXTIRPATED.

DR. F. DIONISIO reports (*Gazzetta delle Cliniche*, 1885, No. 10) the case of Signora P. P——, aged thirty, who at sixteen experienced some difficulty of breathing, and shortly afterwards noticed slight enlargement in the median portion of the thyroid body. Stationary at first, the tumour began to grow and extended to the right side. At twenty years of age, when the lady was married, another swelling appeared on the left side of the neck and developed rapidly. Iodine treatment was tried internally and by injection, but the patient suffered severely from iodism without any compensating advantage. In the spring of 1885, the tumours having grown to such an extent that the slightest bend of the neck was impossible and the difficulty in breathing and swallowing had greatly increased, the patient became anxious for a surgical operation at all risks. On examining the neck on April 9th, it was found occupied by two tumours. The largest projected from the middle of the thyroid region to the right, and upwards as far as the mastoid process, raising the sterno-mastoid muscle and extending downwards under the sternum. The fleshy consistence of the tumour and its very limited movements in swallowing or under finger-pressure, which was very ill borne, gave the idea of deep impaction between the sternum and trachea. The second tumour was smaller, softer, and more movable; it was situated between the left side of the trachea and the corresponding sterno-mastoid muscle, and was separated from the right swelling by a skin depression (*solcatura tegumentaria*). Carotid pulsation was felt on the left, not on the right. Large subcutaneous veins were visible over both swellings; over the right they formed a varicose mass which occupied almost the whole clavicular region. The maximum circumference of the neck was forty-four centimetres (seventeen inches and a half). The right tumour was removed on April 19th, the left on July 2nd. Both operations were performed under chloroform, without spray, and by enucleation through two vertical incisions, which were united throughout with interrupted silk sutures, allowing space for a large drainage-tube at each lower angle. A Listerian dressing was applied the first day; subsequently a corrosive sublimate solution (1 to 1000) was injected through the tubes, and the wounds covered with iodoform gauze and antiseptic cotton. The hæmorrhage was inconsiderable. The first operation lasted a little less, the second rather more, than an hour. Convalescence was rapid, the temperature never rose above 38°, and both wounds healed throughout by the first intention. Two months later two linear parallel cicatrices were visible on the front of the neck, which now measured in circumference thirty-four centimetres (thirteen inches and a half). All trace of vascular dilatation had disappeared; respiration, deglutition, and general health were perfectly restored. The tumours weighed 350 centigrammes, and were microscopically examined by Professor Bizzozero. The left tumour was formed of a stroma of connective tissue, more abundant than the stroma of the normal thyroid, of hyaline aspect, and containing numerous anastomosing tubules covered with a single layer of epithelial cells; some of the tubules were dilated, and contained a colloid substance. The right swelling consisted of several zones of rather loose connective tissue, containing a large number of alveoli of various sizes, round or elongated, lined with simple tesselated epithelium and filled with granular masses or colloid substance, recalling the structure of common adenoma of the thyroid. In other parts the alveoli were smaller and more elongated, with the lumen proportionately reduced and obliterated in some points, so that the soft connective tissue, here and there infiltrated with amorphous matter of colloid aspect, appeared traversed by solid cords which frequently anastomosed. This was regarded as the form of adenoma most closely approaching the structure of cancer, and in reality not separated by a defined limit from the class of cancerous tumours.

RIVER POLLUTION IN SPAIN.

THE more closely we investigate the recent cholera epidemic in Spain, the clearer becomes the connexion between the water-courses and the districts affected. Under such circumstances the necessity of a Rivers Pollution Act is very obvious. If arguments were wanting in favour of such legislation, we might point to the town of Granada. Of all the large towns in Spain, none suffered so severely; and yet it is possible that the epidemic might have been avoided if the river that passes through this ancient city had been protected by a law rigorously applied. Some ten miles further up the river, just where the stream called the Aquas Blancas joins the Genil, there are some large paper-mills. A part of the water is used for the paper manufacture, and in the dry summer months all the water passes through the mills. The roughest chemical tests suffice to show the impurities resulting. The water is somewhat clearer before reaching Granada, but it is still utterly unsuited for drinking purposes. In spite of this, there are two intakes of drinking-water below the factory—namely, the canals, or *acequias*, Del Candil and Real. It should further be noted that the first cases of cholera at Granada occurred in the districts supplied by these canals, for there are three other sources of water used in the town. The general insanitary condition of Granada is such as to readily account for the rapid spread of cholera when once introduced; but perhaps we have in the connexion between the paper-mills and the potable water the origin of its first appearance. The rags employed for the manufacture of the paper were imported from the province of Valencia, where the cholera had been raging for some time. The unpacking and sorting of such unwholesome and filthy wares on the banks of an uncovered stream may well have contaminated the water. Indeed, this obvious danger caused considerable agitation

Digitized by Google

at the time. The inhabitants of Granada clamoured to have the mills closed. This undoubtedly would have been done had they not belonged to the German consul; and the incident relating to the Caroline Islands had already sufficiently embittered the relations between Spain and Germany. When, however, Granada became itself a source of infection, the inhabitants altogether failed to take any precautions for preventing the further pollution of the river as it passed through their town. Together with the Darfo, the Genil forms the main sewer of Granada, and yet further down on its course there are numerous villages and towns whose inhabitants drink its waters. This river consequently carried the cholera through the province of Granada, and even into the province of Cordova. One after another the villages and towns on either bank were invaded by the dread disease, the town of Loja, with its 12,000 inhabitants, alone enjoying comparative immunity. Here there were only two or three cases a day, the maximum being seven cases; but the people were not in the habit of drinking the waters of the Genil; they had a different and a pure supply. Similar illustrations of the fatal effects resulting from river pollution will be found throughout Spain: and there can be no difficulty whatever of establishing the necessity of stringent legislation on this subject.

LITHÆMIA, OXALURIA, AND PHOSPHATURIA.

ARE there such things as lithæmia, oxaluria, and phosphaturia? If so, are they mere accidents, or are they to be associated with a diathesis? Has each a separate significance and diathesis, or do they run into each other and interchange? Which is the organ or organs most at fault? Is it the nervous system or the digestive system, or that greatest of all sinners, the liver? What are the relations of such states of the urine to nervous symptoms, such as vertigo and palpitation, to hysteria, to flatulence, to rhematism, to gout? Such are the kind of questions which have been discussed in a very interesting paper by Dr. C. L. Dana, at a meeting of the Practitioners' Society of New York, and in an equally interesting and well-sustained discussion which followed, and which has been reported in the New York journals. We can only indicate the principal points in the views of Dr. Dana. He thinks the term "oxaluria" might be dispensed with, and that oxaluria is oftenest only an indication of lithiasis. In about one-fifth of the cases showing exaggerated nerve-irritability he has found evidence of over-acid urine, with excess of urates, and benefit has followed anti-lithic treatment. In some cases, even where the urine was cloudy and feebly acid, he has found on analysis—and he insists on careful analysis of the urine in such cases—that there was in reality a small amount of phosphates and an excess of urates. We certainly do meet in practice now and again a case with flatulence, vertigo, palpitation, perhaps retching, great distress and fear, and probably depression, in which the urine is excessive, alternately loaded with phosphates, and charged with coarse crystals of uric acid. Dr. Dana gives the case of a married woman aged fifty, who complained of great nervousness, confusion of mind, irritability, and depression. She had no organic disease anywhere. Her father died insane; her mother was rheumatic; of seven brothers and sisters nearly all were rheumatic, but had no nervous troubles. She had some muscular pains. Her urine was cloudy with phosphates, neutral. On precipitation with Teissier's solution the phosphates were below normal, the urine, on the first test, acid, sp. gr. 1022, with an excess of phosphates and a slight excess of urates. Under bicarbonate of potash there was slight improvement. In none of his 110 cases, in which urinary and nerve troubles were combined, was he able to get the slightest evidence of developed gout. He finds that in cases of neurasthenia of the gastric type there is often an excess of uric acid or some rheumatic taint, to which treatment should be directed. Phosphaturia, so-called, he seems more doubtful about, and when it does happen regards it as due to either a peculiar diet or insufficient innervation of the digestive organs, to be treated by mineral acids, strychnine, &c. But in the vast majority of cases phosphaturia is only an evidence of indigestion. Not only in Dr. Dana's paper, but in the discussion which followed, the thing which strikes us most is the praise given to a nitrogenous diet and the regulation of the liver—an organ for which Dr. A. A. Smith said his respect was constantly increasing.

A LIQUOR LICENCE FOR THE EAST LONDON PEOPLE'S PALACE.

THE question whether a liquor licence should be added to the other attractions of the People's Palace for East London has not been asked too early. There can be little doubt that the answer to this question will have an important bearing upon the future of the institution. The founder's intention, also, with regard to such a question should not, if we understand aright the object of the Beaumont Trust, be difficult to determine. The idea evidently is that a centre of culture combined with recreation should be formed for the proper benefit of a large body of the public, especially the artisan public, of London. It recognises the fact that the national intelligence requires development in every grade of the social scale, and it aims at extending more widely than heretofore the influences which refine life and which commonly come of well-directed education. The accomplishment of these ends would certainly be rather hindered than helped by the introduction of a bar in the proposed Palace. Experience testifies in favour of abstinence as a guarantee for order. The principle of temperance, moreover, is diffusing itself among all classes, and there is no reason to think that the popularity of this institution would be lessened by its public assertion there. Necessity can hardly be shown for an opposite course. It would certainly be wise to have within easy reach a supply of stimulants to be used in cases of emergency from illness or accident, but any provision for a freer traffic in intoxicants would, in our opinion, be a mistake.

THE ETIOLOGY OF BERI-BERI.

AN interesting contribution to the knowledge of the disease Beri-beri has recently been made by Dr. Lacerda, director of the physiological laboratory in Rio de Janeiro. During a visit to the island of Marajó he investigated with a good deal of care, and with the help of Senor Gustavo Rumbelsperger, an epizootic prevalent there, affecting chiefly horses and pigs, and known by the names "hip pestilence," "quebrabunda," "straddling disease," and came to the conclusion that this was identical with Beri-beri. The first symptom is debility, the animal losing its natural vivacity; it then walks with an uneven gait, its nostrils dilate, and its breath becomes short, and the penis is protruded from the prepuce; it then becomes restless and unwilling to remain in one position, constantly varying the point of support for the hind legs, keeping one of them always at rest. Shortly the characteristic symptom of staggering in the hind legs appears, the horse seeming to have broken his haunches and being unable to control the movements of his hind legs; the abdomen is retracted, the stools voided with difficulty as hard lumps, sometimes covered with mucus; there is also dysuria. Usually there is neither anorexia nor great thirst, and only in rare instances is there any fever. Sometimes paralysis and dropsies appear; ulceration, emaciation, and atrophy are also observed. The disease proves fatal occasionally in a few days, but some horses linger for weeks or months. Twenty-two necropsies were made, the blood being

Digitized by Google

dark and viscous, and the viscera dark, swollen, and softened with ecchymoses in the bladder and omentum. The medulla presented sclerosis variously diffused, also a number of cells like the generative organs of ascomycetes and some mycelium. The water of Lake Arary in the island was found to contain a polymorphous microphyte belonging to the group Ascomycetes. This in its original condition, as well as when passed through several cultivations, produced in rabbits, pigs, birds, and monkeys inoculated with it symptoms closely resembling those of the "hip pestilence." The post-mortem appearances and cultivations of the blood in both cases were so similar that Dr. Lacerda was led to believe that the "hip pestilence" is due to drinking the water of the lake. He, moreover, concludes from the symptoms and pathological appearances of Beri-beri that it is also identical with the "hip pestilence" of Marajó. His pamphlet is illustrated by excellent engravings and photographs, and had it been written in some language more read by European medical men than Portuguese, it would probably have attracted some attention.

A SCURVY-STRICKEN CREW.

FOUR of the crew of the *Medusa*, owned by London shipowners, were admitted into the Seamen's Hospital last week suffering severely from scurvy. The ship had been about 150 days on her passage from Cocos Island in the Bay of Bengal, and during the voyage every member of the ship's company had suffered more or less from scurvy, whilst one seaman had died and was buried at sea. It may be suggested that he did not die from scurvy, but as his legs presented the large discolourations characteristic of the disease some two or three days before he died, and as shortness of breath was his most prominent symptom, we may fairly assume that it was probably one of the usual pulmonary complications of severe scurvy that killed him. The crew lived on salt beef and salt pork of variable quality, and bread that towards the end of the voyage was so mouldy and weevilly as to be absolutely uneatable. For some six or seven weeks after sailing eight pounds of preserved meat were served up once a week, and divided among twenty men — i.e., two-fifths of a pound per man once a week. The lime-juice is stated to have been excessively sour. It is quite exceptional for us to record in late years that four men have been admitted into one hospital with this disease from a British ship, and we hope that the Board of Trade will not stop at merely sending a medical inspector to inquire into the circumstances. There cannot be a doubt that great neglect or carelessness must have existed in provisioning the vessel for the homeward voyage, and it is most unjust to the crew that the question of responsibility should be quietly allowed to drop.

ENTERIC FEVER AT SUAKIM.

THE etiology, nature, clinical course, and pathology of enteric fever and its subtropical associates formed the ground for an interesting discussion on Dr. J. E. Squire's paper read before the last meeting of the Royal Medical and Chirurgical Society, which occupied the whole evening. Army medical men were to the front, and some valuable material was contributed, especially by Dr. Marston, as well as some weighty remarks on the nature of the diseases by Dr. Broadbent. The interest chiefly centred about the pathological nature of a disease or diseases avowedly possessing some clinical similitude. It appears to be not improbable that we are really concerned with at least two distinct affections. Notwithstanding that on this point a diversity of opinion prevails, we must give our adhesion rather to the view put forward by Dr. Broadbent, who believes that a typho-malarial fever exists distinct and separate from typhoid fever. The view that the so-called typho-malarial affection is a greatly modified form of enteric fever is a hypothesis worthy of entertainment, though, on Dr. Broadbent's showing, the clinical course of each malady, though having a certain resemblance in the protracted high pyrexia, differs nevertheless in many particulars, while the post-mortem phenomena have a marked contrast in the absence of intestinal ulceration in the one case, and its presence in the other. In his paper Dr. Squire appeared to show that the enteric disease at Suakim chiefly attacked those soldiers who had resided for some time in the district, but Dr. Marston brought forward some weighty facts, lending powerful support to the view that recent arrivals in an infected district were most prone to take the disease, and that age exercised considerable influence in the same direction. We do not appear to have arrived at any further knowledge on the vexed question of the mode of origin and dissemination of typhoid fever, though one speaker emphatically adopted what he called the military as opposed to the civil view, that enteric fever was frequently of spontaneous origin. In this respect he had the support of the authority of the late Dr. Murchison, whose name of "pythogenic fever" still rings in the memory of those who follow the teaching of this master on the subject of continued fevers. Whether the cause of malarial fever and that of enteric fever fuse in a sort of chemical fashion to produce in the human body a new kind of disease is a moot point. In this regard Dr. Broadbent, confining himself to the nature of the diseases, and believing that at least two affections were in question, expressed no positive opinion as to the etiology of the typho-malarial disease.

FOREIGN MEDICAL APPOINTMENTS.

DR. HIS, Professor of Anatomy in Leipsig, and Dr. Gegenbaur, Professor in Heidelberg, have been elected Corresponding Members of the St. Petersburg Academy of Sciences. Dr. Furbringer of Vienna has been selected out of twenty-four candidates as successor to Dr. Riess at the Municipal Hospital in Friedrichshain, near Berlin. Dr. Joh. Janosik has been appointed Professor of Histology and Embryology in the Czechish Medical Faculty of Prague. Dr. Sattler, Professor of Ophthalmic Surgery in Erlangen, has accepted a "ruf" to Prague. Professor von Recklinghausen, of Strasburg, has been elected a Corresponding Member of the Berlin Academy of Sciences.

POLLUTION OF RIVERS.

A DEPUTATION last Friday waited on the Lord Mayor to request the use of the Mansion House for the purpose of holding a public meeting on the subject of rivers pollution. The Lord Mayor, in consenting, stated that the matter was of immense importance, that every day there was emptied into the Thames at Crossness from 80,000,000 to 120,000,000 gallons of sewage matter, and that rivers should be as free from pollution as practicable. He decided that the meeting should be held on Wednesday, March 10th. In the meantime the Lea Conservancy Board have not been idle, but have proceeded in the Hertford County Court against the Ware Board of Guardians, the rural sanitary authority of that district, for allowing sewage to go from Hoddesden Sewage Farm into a ditch or water-course, a tributary of the river Lea. The decision of his Honour Judge Abdy is of much importance as showing that the Conservancy Board have very considerable powers for the prevention of the pollution of that river. The sewage, it was proved in evidence, was conveyed to a farm owned by the sanitary authority but leased to a farmer, and which is bounded by a ditch. The sewage escaped from the ditch into three channels, and

Digitized by Google

thus into the Lea, but these channels were not the property of the sanitary authority. It was argued on behalf of the latter board that they were not responsible on this account, and also because the farm was not in their immediate possession, but his Honour, in giving judgment on these and other minor points, decided against them, and made an order requiring them to abstain from committing the nuisance within two months.

RECURRENCE OF TYPHOID FEVER AT KIDDERMINSTER.

A RECENT recurrence of typhoid fever at Kidderminster has been associated with the discovery of conditions affecting the water-supply of the town, which are of serious importance. It will be remembered that when the town was last year visited with the disastrous epidemic on which we commented at some length, it was not found possible to state with certainty what relation the water-supply had had to the outbreak. The town exhibited so many of the conditions with which typhoid fever is habitually identified that suspicion attached to many other things besides water, and it is certain that some of these, such as the state of the sewers, afforded ample means for the dissemination of the infection when once introduced. But all along there were grave grounds for fearing that the lower well might have become polluted by means of circumstances connected with the neighbouring sewage tanks. The lower well was not originally intended to serve as a well; it was indeed a "sump," to take away water from the vicinity of the sewage tanks. But as nothing definite could be discovered concerning it in relation to the epidemic, the well was not abandoned, but it was tubed, and the space outside the tube was filled in with concrete, pending the provision of a supply which should be above all suspicion, and which had been recommended by Dr. Parsons in his report to the Local Government Board. Since then, however, no special steps appear to have been taken to provide such a supply, and the well water being again used, it appears that some fresh excavations have led to the discovery of an old drain, twenty feet below a footpath by the side of the well, and this drain is stated to have contained a quantity of black matter resembling sewage. Once again the supply has been stopped, and Dr. Parsons, as also Mr. A. Taylor, of the Engineering Department of the Local Government Board, have visited Kidderminster with a view of ascertaining what is the true significance of the discovery which has been made. Even now it is by no means certain that the continuance of typhoid fever in Kidderminster is due to the use of this water; indeed, so far we do not gather that the distribution of the cases has any definite relation to the distribution of this special water-supply. It must also be remembered that, in view of the sanitary circumstances of Kidderminster, as revealed by Dr. Parsons, there is nothing striking in the recurrence of cases of typhoid fever after such an epidemic as the town suffered from. Indeed it is most difficult, when hundreds of centres of infection have been scattered about a town, to get rid of the possibility of such recrudescences as have occurred in this case. But one thing appears tolerably certain, and that is that the relation of this lower well to the sewage works and to certain drains is such that no one can say that the water-supply is not subject to the risk of pollution, and under the circumstances it cannot be right to go on supplying such a water to the population. The duty of the Town Council is to supply the inhabitants with a wholesome water, and the mere fact that chemical analysis has proved to [illegible] wholesome is no reason for continuing to receive the supply from this well [illegible] of the dangerous surroundings, and of the conditions already discovered in its immediate neighbourhood. Dr. Parsons from the first urged the Town Council to abandon this suspected well, and to procure a supply which should be free from all risk of pollution. No delay that can be avoided should take place in giving effect to this recommendation.

ATTENDANCE BY UNQUALIFIED ASSISTANTS.

THE Leeds papers contain the report of a decision by the County Court judge in several cases in which a practitioner, Mr. H. A. Allbutt, was the plaintiff, who sought to recover charges for medical attendance which had been chiefly paid through an unqualified assistant, living at a separate house at Hunslet. The name on the house was that of the unqualified assistant, and the house is really his (Mr. W. H. G. Bowell's), and not that of Mr. Allbutt, who lives in Leeds. The bills were made out in the name of Mr. Allbutt, and he was supposed to see serious cases. The judge ruled that the charges by Mr. Allbutt could not be recovered, because it was only a fully qualified man who could recover, and that must be when he practised himself, and did not carry it on by living away from the place. This decision can surprise no medical man after the severe way in which both the Medical Council and the Courts have regarded a system of the kind involved in the above arrangements. The case is in one respect not so bad as some. The assistant's name was boldly placed over the house, so that people had the means of knowing that they might expect to be attended by him and not by Mr. Allbutt. But it is clearly possible that many people might be deceived into thinking that Mr. Bowell was a qualified man. In one of the cases Mr. Allbutt had not seen the patient at all. In others he had seen them several times. But in all the cases the judge gave a verdict for the defendant, and described the practice as illegal.

LEAD-POISONING BY HOUSEHOLD UTENSILS.

THE German Parliament has now under consideration a Bill which is intended to regulate the employment of lead in the manufacture of cooking and other domestic utensils, and so to diminish the risk of poisoning by that metal. The provisions of this measure certainly do not err on the side of leniency. They forbid the use of vessels containing more than 10 per cent. of lead in their composition for the above purposes. No alloy with over 1 per cent. may be used in coating iron articles used in cookery. Solder may consist of lead to one-tenth of its amount, but no more. Enamels into which lead enters are treated with equal stringency. The effect of this Bill, if it be passed, will be to obliterate the legal existence of pewter and of soft solder as at present made, since these alloys contain from one-half to one-fourth of their weight of lead. One fact which it brings into prominence is that lead-poisoning in Germany appears to arise from other causes besides those to which it is commonly attributed in this country. Cases of this kind among ourselves are usually found in the persons of those who are actually engaged in handling lead or its compounds in their daily occupation. Plumbers, painters, glass-blowers, glaziers, potters, and enamel-card makers furnish the majority of those who suffer from plumbism. When this disorder appears in the household, new paint in the walls or the lead work of the water service affords a clue to its detection. It is comparatively rare to find in these days that pewter pots or cooking utensils are at fault. This may be because glass is used on the whole far more frequently than pewter in the liquor trade; while in the kitchen those vessels the contents of which are most likely to become contaminated with lead in the solder—such, for example, as preserving pans—are usually made of brass or copper (which is kept well burnished), and present a relatively trifling soldered surface, or are lined with porcelain. The water

Digitized by Google

used in cooking also acts as a protective, since the lime salts contained in it tend to prevent the solution of lead. The proposed German legislation on this subject is very perfect in theory so far as it goes. Possibly it may be called for by the teaching of experience. In this country it would probably be found to be needlessly severe, and would not cover the chief causes of the evil which it is intended to meet. We do not see how it can do this even in Germany, unless measures of equal rigour be adopted to control the use of lead in manufactures and in its other domestic applications. The introduction of these further restrictions might fitly exercise the judgment of our own as well as foreign legislators.

THE SURGICAL TREATMENT OF ACUTE NECROSIS.

THE diseases of bone occurring before the growth of the body is completed, or at least before the bones themselves have attained their ultimate length, appear to possess more interest than similar diseases in the adult, not only on account of their greater physiological bearings, but from their pathological and clinical importance. The discussion on Mr. Bernard Pitts' paper, read before the Medical Society of London, showed the keen interest that surgeons take in these diseases, as well as the impossibility of estimating certain pathological conditions pertaining to the osseous lesion. A knowledge of the depth to which the necrosis extends is far more difficult of attainment than an estimate of the extent or length of bone involved. The first case narrated by Mr. Pitts illustrates the advantage of opportune but conservative surgical interference in cases of limited necrosis when the patient's constitutional powers are flagging, as well as the circumstance that the removal of even a considerable amount of new bone need give rise to but little apprehension as to the ultimate successful regeneration of a large part of the shaft of the tibia. As Mr. Pearce Gould remarked, we needed some simple means for appraising the depth to which necrosis extended; but still, in Mr. Pitts' case, it was a question of local treatment not for local ends but for constitutional welfare, for under expectant treatment the patient was slowly sinking; and so the consideration of a little living bone, more or less, was not a matter of the first magnitude. Whether in some cases of a more chronic sort and with less lowering of general health, the adoption of M. Ollier's method of trephining the diseased bone in attempting to estimate the situation of the line between living and dead bone in the thickness of the diaphysis can be made practically available for surgical purposes appears to admit of some doubt, and there is always the chance that fresh absorptive processes may be set up, with their pyæmic outlook.

THE SANITARY STATE OF MILE-END.

MR. T. HAMER, of the Mansion House Council, challenges the accuracy of certain statistics which the vestry recently submitted at the public inquiry into the sanitary condition of Mile-end Old Town, and from which it appeared that, according to Dr. Corner's last annual report, the death-rate from zymotic diseases was only 1·2 per 1000. Dr. G. B. Longstaff, whose accuracy as a statistician is above all suspicion, has reported to the Mansion House Council that the rate should properly be 3·6 per 1000. The difference appears to be due to several causes. According to Mr. Hamer, Dr. Corner in one of his tables states that there were no deaths from enteric fever, whereas elsewhere he admits that there were 16 from typhoid fever, which everyone nowadays knows is the same disease. Then, again, the deaths which occurred amongst Mile-end residents in the Metropolitan Asylums and hospitals are apparently excluded from the figures on which Dr. Corner's rate was founded. But apart from this, Dr. Longstaff shows that, whereas Dr. Corner's figures only show 140 deaths from the so-called zymotic diseases, the Registrar-General's returns show 350. This difference is largely due to the fact that Dr. Corner has not included diarrhœa as a zymotic disease. This, of course, he is entirely at liberty to do, for there is hardly any more unfortunate term in use than that which lumps together such diseases as diarrhœa, whooping-cough, &c., under one heading, whilst all skilled observers know that in so far as sanitary circumstances are concerned they have nothing in common. Still, where comparisons are made the same diseases must, of course be dealt with.

MYCETOMA AND ACTINOMYCES.

AT the last meeting of the Medical and Physical Society of Bombay, held on Jan. 8th, the President, in exhibiting a patient affected with mycetoma (ochroid form), took occasion to point out the similarity of aspect as regards form, size, differentiation of parts, and general arrangement of the characteristic pale particles of mycetoma, as compared with a representation of the actinomyces body given in the English translation of Ziegler's Pathological Text-book (vol. ii., p. 243), upon the authority of Dr. Sims Woodhead. Several members of the Society, including the past and present teachers of pathology in the Grant Medical College, after scrutinising the specimens and drawing, agreed that such resemblance was indubitable. A note was also handed in briefly summing up the main points of likeness and difference between the two diseases in question, and stating that in the pale mycetoma bodies neither bacilli nor other defined bacterial organisms were visible after staining by the usual methods. Should subsequent inquiry establish the identity between one form at least of actinomyces with a frequent variety of mycetoma, it will be worth recollecting that the fungus disease of India was identified in 1859 (*vide* Dr. V. Carter's essay in the Society's Transactions for 1860), the corresponding parasitic affection of Europe being made known in 1877-79.

THE MEDICAL COUNCIL AND THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE Royal College of Surgeons in Ireland have again elected Mr. Rawdon Macnamara to represent the College in the General Medical Council. His election was not without opposition. We do not always agree with Mr. Macnamara, who believes too absolutely in all existing institutions, and especially in his own college, and all its regulations. But such a quality does not explain the opposition to his election, the failure of which, we fancy, most of Mr. Macnamara's colleagues in the Council will not regret, for though always ready to hold his own, he does so with uniform good temper and much ability.

MICROBES OF INFECTIVE OSTEO-MYELITIS.

M. BERTOYE has reinvestigated this subject, and discovered the staphylococcus pyogenes albus, which he has succeeded in cultivating in bouillon and in transforming into coccus aureus. By intravenous inoculation in a rabbit osseous lesions and purulent disseminated foci have resulted. Cultivation of the morbid products of the induced disease led to the development of the orange-coloured micro-organism. He believes that the microbe of osteo-myelitis can be made to give rise in bone and other tissues, and especially the skin, to chronic suppurations without local or general reaction—in other words, to an attenuated form of the disease. The microbe takes on the white form in some cases of the attenuated malady. The staphylococcus albus may be transformed into the staphylococcus aureus by being sown in and passing through different animal media.

Digitized by Google

These cultivations have been shown by M. Rodet to increase the vitality and the virulence of the micro-organism, and it seems reasonable to connect this augmentation with the change in colour. The modification in virulence and colour of the staphylococcus albus may possibly be due to a massing together of the microbes. It will be perceived that on M. Bertoye's showing the microbe of osteo-myelitis gives rise to an attenuated form of the disease when it presents itself under the white aspect and, consequently, when the density of its colonies is least marked.

SUBCUTANEOUS INJECTION OF OXIDES OF MERCURY.

SUBCUTANEOUS injections of the black and red oxides of mercury have been recently tried as an anti-syphilitic treatment in the Lazarus Hospital at Warsaw by Dr. von Watraszewski, who has charge of the syphilitic wards. He finds that no inflammation and scarcely any pain is produced, no abscess having occurred after any of the 200 injections he has performed. The therapeutic results were most satisfactory both in recent cases and in those where the disease was of old standing.

THE DARLINGTON HOSPITAL.

A CORRESPONDENT writes:—"The whole of the honorary staff of the Darlington Hospital have sent in their resignations to the committee, owing to the extremely unsatisfactory condition of the nursing department, and the refusal on the part of the committee to take necessary measures to ensure reform. There have been several changes of house-surgeons during the last twelve months on account of the same difficulty."

ANTIPYRIN IN PHTHISIS AT DAVOS.

DR. HOEDMAKER, a Dutch physician, practising at Davos Platz, has made a number of observations on the effect of antipyrin on phthisical patients, from which he has come to the conclusion that patients not treated with antipyrin are more comfortable than those who are taking it, though these latter have less fever. He has found salicylic acid most valuable in phthisis, especially when combined with arsenic.

CHOLERA IN SPAIN.

THERE has for some months past been rumours of the continued prevalence of cholera in different parts of Spain, and now definite intelligence comes from Gibraltar to the effect that several fatal attacks have occurred at Tarifa, the most southern point of the peninsula.

DR. DIPLOCK, coroner for West Middlesex, has just forwarded to the Home Office his annual report of the number of inquests and an analysis of the verdicts for the year 1885. During that period there were 1091 cases reported to him, in 250 of which, after investigation, he did not consider inquests necessary. The number of inquests held was thus 841, and these are classified as follows:—On persons under one year, 250; above one year and under sixteen years, 152; above that age, 439. The amount expended in fees &c. was £1623. The population of the forty-nine parishes and districts comprising the Western Division of Middlesex is about 629,000.

AN epidemic of typhus fever, believed to be largely the result of squalor and destitution, has broken out in a district of Leeds inhabited by the poorest class. The officers of the sanitary department have adopted precautions to check the disease.

A FEW weeks ago we called attention to the sad death of a lady at Sunderland through swallowing a set of false teeth, and cautioned the users of these appliances against such accidents. Another death from the same cause—that of a gentleman at Dublin—has just occurred, and again we urge, on the joint grounds of cleanliness and safety, the removal of such teeth at the time of retiring for the night. It is the duty of medical men, no less than of the dentist who supplies these articles, to point out to the patients the advisability of such procedure, and the dangers attending a neglect of so plain a duty.

A NEW Russian journal devoted to surgery is about to be brought out under the auspices of Professors Sklifosofski and Tauber. The editorship of the journal *Practicheskaya Meditsina* (Practical Medicine), vacant by the decease of Dr. Hirschfeld, has been undertaken by Dr. M. J. Afanasyeff, private lecturer in the St. Petersburg Military Medical Academy.

ON Monday week last, February 1st, at the London Hospital, Mr. Frederick Treves removed from a woman, aged thirty-five, the left kidney, together with both ovaries—the kidney for hydronephrosis, the ovaries for multilocular cystomata. The patient, we understand, is doing remarkably well.

ON the 10th inst., Dr. Angus Macdonald expired at his residence in Edinburgh. The deceased, who was fifty years of age, was four years ago compelled for nearly twelve months to abandon all professional duty and seek repose in the south of France, and since then he has, it is supposed, overworked himself.

PROFESSOR C. G. SANTESSON, one of the most renowned surgeons in Sweden, who was attached to the Carolina Institute in Stockholm, has just died, at the age of seventy-six, from cardiac disease. The deceased professor studied in Stockholm, Upsala, and Copenhagen.

MR. R. MONTGOMERY M.R.C.S., Governor of the Apothecaries Hall, Ireland, has been appointed Secretary of that body, in place of Dr. E. H. Leet, resigned.

DR. LUCHSINGER, Professor of Physiology in Zurich, has died at Meran. It is expected that Dr. Gaule, who has been lecturing for him, will be elected.

MR. THOMAS WARNER, J.P., a well-known and widely respected surgeon, died on the 7th inst. at his residence in Cirencester, at an advanced age.

THE Prussian Order of the Red Eagle, third class, has been conferred on Dr. Bergmann, Professor of Surgery in Berlin.

DR. HORNER, Professor of Ophthalmology in Zurich, has been obliged by ill-health to give up his post.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—The annual meeting of the governors of this institution was held on the 10th inst. The number of new patients during the past twelve months was 6630, and of these 129 received in-door treatment. Since the institution of the charity in 1857, 103,901 patients have been relieved, and, notwithstanding the strictest economy compatible with efficiency, the expenditure during 1885 considerably exceeded the income. The committee earnestly plead for continued and increased funds.

MR. T. PRIDGIN TEALE ON FIREPLACE CONSTRUCTION.

SIR ROBERT CHRISTISON in his autobiography, which we trust soon to notice, shows us how narrowly the science and art of surgery escaped losing the genius of Syme by his aptitude for practical chemistry. The discourse of Mr. Teale on Friday night, at the Royal Institution, shows how easily the surgical art might have lost him had he given early reins to his mechanical faculties. The subject of firegrates may seem one somewhat alien to the surgical mind, but if the studies of Mr. Teale lead to less poisoning of the atmosphere by the products of coal consumption, and to greater warmth of our houses in inclement weather like this, he will have earned the gratitude of the public and of invalids; and if he reduces the cost of coals by one-fourth, he will deserve the thanks of all who in these hard times have difficulty in making ends meet. The audience, presided over by Lord Bramwell, and including Sir William Bowman and other distinguished persons, was numerous and most attentive. We may take this opportunity of saying that Mr. Teale's fireplace may be seen at Nelson's, 10, Royal Arcade, Old Bond-street. We shall best describe Mr. Teale's views as to the principles of domestic fireplace construction by quoting his rules, which he states with great brevity, and which are as follows:—1. As little iron as possible is to be used. 2. The back and sides of the fireplace should be of brick or firebrick. 3. The firebrick back should lean over the fire, and not lean away from it. 4. The bottom of the fire, or grating, should be deep from before backwards, probably not less than nine inches for a small room, or more than eleven inches for a large one. 5. The sides or coverings of the fireplace should incline to one another, as the sides of an equilateral triangle. 6. The lean-over at the back should be at an angle of 70°. 7. The shape of the grate should be based on a square described within an equilateral triangle, the size to vary in constant proportion to the side of the square. 8. The slits in the grating, or grid, should be narrow, perhaps a quarter of an inch for a sitting-room grate and good coal, and three-eighths of an inch for a kitchen grate and bad coal. When the slits are larger they allow cinders to fall through—in other words, waste. 9. The front bars should be vertical, that ashes may not lodge and look untidy, narrow (perhaps a quarter of an inch in thickness), so as not to obstruct heat, and close together (perhaps three-quarters of an inch apart), so as to prevent coal and cinders from falling on the hearth. 10. There should be a rim an inch or an inch and a half in depth round the lower insertion of the vertical bars. 11. The chamber under the fire should be closed by a shield or economiser. 12. Whenever a fireplace is constructed on these principles, it must be remembered that a greater body of heat is accumulated about the hearth than in ordinary fireplaces, and corresponding care taken by an ashpan against heating wooden beams, &c. This ash-pan should have a double bottom, the space between the two plates being filled with artificial asbestos, slagwood two inches in thickness. 13. A fireplace on this construction must not be put in a party wall where there is no projecting chimney-breast, lest the heated back should endanger woodwork in a room at the other side. The benefits aimed at by Mr. Teale are:—1. Economy of fuel. 2. Reduction of soot. 3. Reduction of dirt refuse. Mr. Teale astonished his audience by showing two small glass bottles containing the small ash residue of the coal burnt in his fireplaces, which consisted not of cinders, but very fine powder. As to the saving of coal, the general manager of the Leeds Infirmary estimates that in that institution it amounts to a sixth, or 100 tons in the year. We have only space left to say that from some observation of Mr. Teale's own fireplaces, and some experience of them, we believe he has got hold of the right principles and in a large measure of the details. He was careful with the true candour of a scientific man, to show how curiously his discoveries were anticipated last century by that remarkable man Count Rumford, who did study medicine, but, unlike Syme and Teale, drifted into other pursuits and was lost to the medical art.

HEALTH OF THE UNITED STATES ARMY.

FROM the Report of the Surgeon-General of the United States Army, we learn that the general health of the troops has been exceptionally good. The respiratory organs were most frequently affected, there being 83 cases of pneumonia amongst 24,035 men, the mortality from this disease being 25 per cent. of the cases. The report tends to show that the native-born American soldier has a greater power of resisting disease and death than the foreign members of the Army. Of these the mortality is greatest amongst the Irish, the Germans coming next, and the English last. The money value of the medical and hospital supplies for the fiscal year, ending June 30th, 1885, was $171,206. In view of the expected approach of the cholera, an appropriation of $250,000 is asked for, for the ensuing year—this increase to provide for emergencies that may arise. During the months of April, May, and June, an Army Medical Board was in session in New York city, and examined nineteen candidates for the position of assistant-surgeon, of which number three were found qualified and sixteen rejected. At present there are no vacancies in the corps. A list is given of the medical officers who have died, at the head of which is Col. and Brev. Brig. Gen. Charles McDougal.

The Surgeon-General recommends the regular organisation of a corps to provide trained cooks, nurses, and attendants for the service of army hospitals. The present system of hospital service by details from the troops garrisoning a post is found to be unsatisfactory and objectionable. He also urges the necessity of providing ice machines for the extremely hot regions of Texas and Arizona, of sufficient capacity to liberally supply the garrison, as a measure not so much of luxury as of necessity for the comfort of the troops and the treatment of the sick. In the matter of hospital stewards, he recommends the enactment of a Bill, providing for two classes—those appointed by the Secretary of War and permanently attached to the Medical Department to constitute the first class, and those appointed by the written order of a commanding officer upon the recommendation of a medical officer to constitute the second class; the monthly pay of the former to be fifty dollars, and the latter twenty-five dollars.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6239 births and 3872 deaths were registered during the week ending February 6th. The annual death-rate in these towns, which had been equal to 23·8, 22·8, and 22·1 per 1000 in the preceding three weeks, was last week 22·2. During the first five weeks of the current quarter the death-rate in these towns averaged 22·6 per 1000, and was 2·2 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 13·4 per 1000 in Brighton, 16·0 in Halifax, 17·7 in Bristol, and 18·3 in Hull. The rates in the other towns ranged upwards to 25.0 in Derby, 26·8 in Blackburn, 27·1 in Manchester, and 27·9 in Portsmouth. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding four weeks from 448 to 360, were 376 last week; they included 175 from whooping-cough, 76 from measles, 35 from scarlet fever, 35 from diarrhœa, 30 from "fever" (principally enteric), 23 from diphtheria, and only 2 from small-pox. No death from any of these zymotic diseases was recorded during last week either in Wolverhampton or in Halifax; whereas they caused the highest death-rates in Nottingham, Plymouth, and Bolton. The greatest mortality from whooping-cough occurred in Portsmouth and Bolton; from measles in Nottingham and Plymouth; and from scarlet fever in Preston, Leicester, and Birkenhead. The 23 deaths from diphtheria in the twenty-eight towns included 14 in London, 2 in Liverpool, and 2 in Sheffield. Small-pox caused but 1 death among the residents of London and its outer ring, 1 in Liverpool, and 1 in Birkenhead; while no death from this cause occurred in any of the twenty-five other large towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around

Digitized by Google

London, which had declined in the preceding twelve weeks from 90 to 22, had further fallen to 18 on Saturday last, and but 1 new case was admitted to these hospitals during the week. The Highgate Small-pox Hospital contained 3 patients on Saturday last, one case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 534, 477, and 478 in the preceding three weeks, were 479 last week, and were, in spite of the cold weather, as many as 166 below the corrected weekly average. The causes of 85, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Sunderland, Brighton, Bolton, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Bradford, and Leicester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·9, 23·1, and 22·4 per 1000 in the preceding three weeks, further declined to 21·3 in the week ending February 6th, and was 0·9 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 13·3 and 16·5 in Leith and Paisley, to 20·3 in Aberdeen and 26·1 in Glasgow. The 527 deaths in the eight towns showed a further decline of 26 from the numbers in recent weeks, and included 9 which were referred to whooping-cough, 6 to scarlet fever, 6 to diarrhœa, 5 to diphtheria, 3 to "fever" (typhus, enteric, or simple), 3 to measles, and not one to small-pox; in all, 32 deaths resulted from these principal zymotic diseases, against 40, 36, and 37 in the preceding three weeks. These 32 deaths were equal to an annual rate of 1·3 per 1000, which was 0·9 below the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to whooping-cough, which had been 6 and 13 in the previous two weeks, declined again last week to 9, all of which occurred in Glasgow. The 6 fatal cases of scarlet fever were also all returned in Glasgow, and also showed a decline from the number in the previous week. Of the 5 deaths referred to diphtheria, exceeding the number in the previous week by 2, 3 occurred in Glasgow, 1 in Aberbeen, and 1 in Leith. The fatal cases of "fever," measles, and diarrhœa were considerably below the average numbers for the time of year. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 160 and 150 in the preceding two weeks, further declined last week to 135, and were 54 below the number returned in the corresponding week of last year. The causes of 75, or more than 14 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 33·3, 29·6, and 31·9 per 1000 in the preceding three weeks, rose to 33·7 in the week ending Feb. 6th, and exceeded by no less than 11·5 the mean rate during the same week in the twenty-eight English towns. During the first five weeks of the current quarter the death-rate in the city averaged 31·5 per 1000; the mean rate during the same period not exceeding 22·6 in London, and 18·4 in Edinburgh. The 228 deaths in Dublin last week showed a further increase of 12 upon the numbers returned in the previous two weeks, and included 26 which were referred to the principal zymotic diseases, against 30, 24, and 15 in the preceding three weeks; 15 resulted from whooping-cough, 6 from "fever" (typhus, enteric, or simple), 3 from scarlet fever, 2 from diarrhœa, and not one either from small-pox, measles, or diphtheria. These 26 deaths were equal to an annual rate of 3·8 per 1000, the rate from the same diseases last week being but 2·6 in London and 0·2 in Edinburgh. The fatal cases of whooping-cough, which had been 19, 17, and 13 in the preceding three weeks, rose again last week to 15. The deaths referred to "fever" and to scarlet fever also showed an increase upon the numbers in recent weeks. Seven inquest cases and 4 deaths from violence were registered; and 59, or more than a quarter of the deaths, were recorded in public institutions. The deaths of infants and of elderly persons showed an increase upon the numbers in the previous week. The causes of 42, or more than 18 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Surgeon-General Howe, Chief of the Medical Department in the Southern District, has just concluded an exhaustive examination of the sanitary condition of the forts and barracks of Portsmouth. Many defects are pointed out in respect of the water-supply, drainage, and the state of the buildings, and in many cases exception is taken to the character of the dietary of the troops.

A recent communication from Coquimbo, Pacific station, contains news of the sudden death of Staff Surgeon John W. Davis, of the *Heroine*. A post-mortem revealed that he died from fatty degeneration of the heart.

INDIA OFFICE.—Deputy Surgeon-General W. A. Thomson, of the Army Medical Staff, has been appointed Principal Medical Officer of the Bombay Army.

ADMIRALTY.—The following appointments have been made:—Fleet Surgeon John Horrocks, M.D., to the *Alexandria;* Fleet Surgeon William J. Wordsworth, to the *Devastation;* Surgeons Christopher Pearson, M.D., and Henry L. Crocker, to the *Excellent;* Surgeons Herbert E. Marsh and W. E. Home, to the *Alexandria;* and Surgeon Edward W. Luther, to the *Hyacinth.*

RIFLE VOLUNTEERS.—2nd Wiltshire: Surgeon George Waylen resigns his commission; also is granted the honorary rank of Surgeon-Major, and permitted to continue to wear the uniform of the corps on his retirement.

Correspondence.

"Audi alteram partem."

THE ROYAL COLLEGE OF SURGEONS.

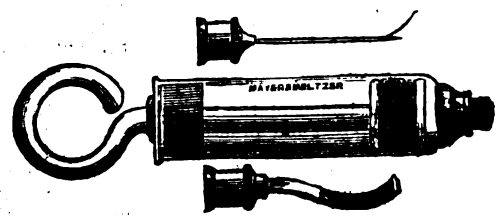
To the Editor of THE LANCET.

SIR,—Mr. Macnamara's sympathies are so obviously with those who are striving to bring about a readjustment of the relations existing between the Council of the College of Surgeons and the other constituent members of the body corporate and politic, that it is perhaps somewhat ungracious to quarrel with the means which he employs to carry those sympathies into effect. But I cannot help thinking that both the proposal which he made at the last meeting of the Council, and the letter which he has addressed to yourself, are calculated rather to hinder than to help a speedy and satisfactory termination of the present controversy. He would solve a constitutional problem by an appeal to the possible prejudices of a small and privileged class. Two large general meetings of Fellows and Members have recently affirmed, by overwhelming majorities, that it is desirable, first, that Fellows and Members should participate more largely in the management and affairs of the College; and, second, that no alteration should be made in the constitution or in the relations of the College, or in any of its bye-laws, without the consent of the Fellows and Members; and, at the meeting held on Dec. 17th it was suggested, in accordance with a resolution adopted by the Association of Fellows and accepted by the Association of Members, that *Members* of the College should be directly represented in the Council. To the first and second of these resolutions the Council, as is well known, has replied by a loose and inconsequential negative; to the third it has, as yet, returned no official answer.

Meanwhile, apparently with the excellent intention of expediting matters, Mr. Macnamara moved at the meeting of the Council held on the 14th ult., that the opinion of the Fellows should be ascertained as to "the advisability of Members being allowed to vote for the election of Fellows as members of the Council"; but a majority of the Council declined to consider Mr. Macnamara's motion "until after the report of the Committee on the Conditions of Admission to the Fellowship has been received." It would be difficult for an ordinary mind to discover any connexion between these two propositions; but no great harm need come of the delay, especially if it should be found that the Council was only trying to gain time and opportunity to give an effectual *coup de grâce* to the outrageous proposal

Digitized by Google

currently ascribed to one of its members to elect fifty Members of the College annually to the Fellowship, and without examination. The collocation of these two events does, however, serve to illustrate the bipartite character of the Fellowship—namely, its academical and its political side. Only the latter is properly concerned in the resolution passed at the general meetings. Viewed from this standpoint, it is certain that, except on the principle "Whatever is, is right," the Fellows have, neither in equity nor in ethics, a greater claim to be consulted than the Members. It is true, the Charter of 1843 gives to the Fellows a presumptive right to consider themselves the sole electoral body; but the abstract justice of this right has always been impugned. This Charter was obtained in violation of every canon of political honour and probity, and when granted provoked almost universal condemnation and disgust, as contemporary records abundantly testify. Nevertheless, the Fellows do at present monopolise the power of electing the Council, and so far as those who have acquired the Fellowship *by examination* are concerned, it cannot be denied that the monopoly has been obtained by fair and honourable means. But the constitutional rights of the Members, dating back to the foundation of the College, have, and must have, precedence over those acquired, long afterwards, by the Fellows. In morals this is so, notwithstanding the fact that the selfish and self-seeking founders of the College did by misrepresentation succeed in excluding the Members (there were no Fellows then) from exercising any control over the management of the College. To believe that the College was established in order "to promote the study and practice of the science and art of surgery" is a pleasant myth, and, like many other pleasant myths, has no solid foundation. The College was established in order to repair the fortunes and restore the discredited prestige of the Court of Assistants of the defunct Corporation of Surgeons. The evils under which we now suffer are the results of the corrupt constitution transmitted to us by the original Court of Assistants. These evils have at length become intolerable, and cannot any longer be silently endured. The most sweeping reform is necessary, and, as a preliminary to this, it is desirable, and, I believe, indispensable, that the Members should be directly represented in the Council. Apart from the reasonableness and justice of this contention, there are many other considerations which tell against the present dispensation. The order of Fellows is a small and diminishing one, while that of Members is a large and increasing one, the present proportion being nearly sixteen Members to every Fellow. And when in the fulness of time the authorities of medical schools, hospitals, and other public institutions come to realise that the Fellowship of the College is no longer the only criterion of high surgical attainments, and when it is decided to select candidates for public offices upon personal and professional grounds alone, one of the chief inducements to take the Fellowship will be withdrawn, and the numbers will still more seriously decline. Nor need this result be deplored if the Council persist in the policy lately pursued with respect to regulations relating to the admission to the Fellowship. But sooner or later the reduction of the number of Fellows will bring us to that point in the vicious circle from which we originally started, and the Council will become again wholly independent and self-propagating. As it is, the Council is a much less representative body than is commonly supposed. It is nominally elected by the Fellows, who number 1100, but the regulations and conditions of voting are so restricted and prohibitive that the election is practically in the hands of less than one-tenth of this number. For example, twenty of the twenty-four present members of the Council were elected by less than a total of 160 votes each, one member being elected by 101 and another by 103 votes. Surely this is tantamount to being elected by personal and private friends. So also is it with the condition of eligibility to be members of Council; these are so exclusive that even under the most liberal provisions of the most liberal Charter barely 100 Fellows can reasonably be said to be eligible. Not only must the candidate be a Fellow, but he must be a Fellow of fourteen years' standing, be in the *bonâ-fide* practice of his profession of a surgeon, *and not be engaged in general practice*. This reduces the area of selection to a few old or middle-aged surgeons connected with the metropolitan hospitals, and one or two rich or enthusiastic provincial surgeons. And yet a body so unrepresentative, and so out of touch with the bulk of the profession, so ignorant of its wants and aspirations or indifferent to them, arrogates to itself the right to speak and act in the name of the Royal College of Surgeons of England, to approach Parliament, and to interpose in matters of State policy. Nor is this the worst. It tyrannises the profession. At the instigation, chiefly, of an interested group of its members, who, contrary to every maxim of public morals and good government, is allowed, as examiners, to absorb a large proportion of the annual revenue of the College, the Council imposes upon the medical teachers and students of this country regulations and conditions which are too often regardless alike of public convenience and of the interests of medical education and public safety. Further, at this moment the Council is engaged in considering and elaborating a scheme by which, in conjunction with the College of Physicians, it may acquire the powers and privileges of a medical university to grant degrees. And, lastly, the Council has been freely and openly referred to by the managers of the Association for promoting a Teaching University for London as a suitable and proper body to form one of the principal factors of a medical faculty. These contingencies only emphasise the urgent and imperative necessity of a reform of the constitution of the College by a large and intelligent extension of the representative principle, without which the Council can neither secure the confidence of the profession nor the right to speak in its name. It was a consideration of these facts, domestic and foreign, that led me to move the following resolution, which was adopted at a general meeting of the Association of Fellows last May (THE LANCET, May 23rd, p. 963)—namely, "That it would conduce to the welfare of the Royal College of Surgeons, and would tend to promote the interests of medical polity and education, if Members of the College were empowered to take part in the election of members of the Council, provided, first, that no Member shall be eligible to vote until he have been such Member for at least ten years; and second, that the number of members of the Council elected by the Members of the College shall not exceed one-third of the whole Council."



I am, Sir, yours truly,

Harley-street, W., Feb. 1886. J. TWEEDY.

INJECTION OR IRRIGATION IN THE EXTRACTION OF CATARACT; ANTISEPTICS; THE PRESENT POSITION OF THE QUESTION.

To the Editor of THE LANCET.

SIR,—My attention has been drawn by a *confrère* to an article in the number of November, 1885, of the *Klinische Monatsblätter fur Augenheilkunde*, by Dr. B. Wicherkiewiez, entitled "Ueber ein neues Verfahren unreife Staare zu operiren nebst Beitrag zur Augen-antiseptik." The method is practically the same as that introduced by me and advocated in my address on "The Treatment of Immature Cataract" to the Ophthalmological Section of the British Medical Association in Belfast in July, 1884. He removes cortex remaining after expulsion of the nucleus by irrigation with a solution of boracic acid of from 1 to 2 per cent.

strength and of a temperature of 30° C. (86° F.), by means of a bottle with a suitable terminal for introduction within the eye. I used likewise an irrigation bottle with terminal, which I exhibited at the meeting, the fluid I employed being distilled water of about the temperature of the body. He states he has operated on nineteen cases with satisfactory results.

I discarded the irrigation or gravitation bottle, and adopted definitely the method of injection by a scoop-syringe, made for me by Messrs. Mayer and Meltzer, and of which the accompanying woodcut gives a fair representation. This method and its advantages I described in detail at a meeting of the Ophthalmological Society of Great Britain

Digitized by Google

and Ireland on October 15th, 1885. (For summary, see THE LANCET, October 24th, 1885.)

Professor Panas of Paris has lately contributed on the subject, as appears by a letter and a communication from your Paris correspondent, both of which appear in your issue of January 16th. The substance of the letter and correspondence is such, however, as to call for remark. Prominence is given to antisepticism, and the injection is only referred to as a means of introducing the antiseptic within the eye. Not a word is said about the object of the injection being to remove cortex. Professor Panas is too able a surgeon to claim for antiseptics all the advantages put forward. It may be good, and it is a distinct addition to our knowledge that we may without risk inject into the eye a solution of 1 part of biniodide of mercury and 20 parts of 90 per cent. alcohol in 20,000 parts of distilled water. The important matter is, however, that by injection within the eye cortex is easily removed, and that cardinal fact must not be put aside by the secondary question of whether pure water or water containing some antiseptic should be used for injection. I hope soon to have the pleasure and advantage of reading Professor Panas' paper, which I have no doubt, judging from the reputation of the author, is a valuable contribution to the subject; but meantime I think it right to put the question in its proper bearing.

I venture to state my conviction, based on a review of my operative experience of the last fifteen years, that the injection, whether of water pure or medicated with suitable antiseptics, to clear out cortex will be found so advantageous as to secure very quickly its general adoption. The advantages are many: a rapid clearing out of the cortex, the removal of cortex, which friction through the lids, pressure, and scoop could not effect; the removal of cortex concealed by the iris; the clearing of the wound and detection of tags of capsule; the diminution of the percentage of loss of vitreous; the shortening of the duration of the operation; less teasing and irritation; less iritis and irido-choroiditis from remnants left in the eye; less regard to maturity, cataracts being mature for the injection operation when immature for others. If the section is large enough for easy expulsion of nucleus, there is no fear about getting out cortex whether the section be large or small, or whether aqueous be freely secreted or not. It is applicable, too, to all sorts of incisions large enough to admit easily the scoop, but I think as a general rule iridectomy should be performed.

With all these advantages we should have less panophthalmitis, suppuration of the cornea, slow healing, iritis, and other accidents after operation. Suppuration and other inflammations in eye surgery depend largely on the amount of traumatism and retention of cortex. We must not ignore, however, the occasional evil influence of septic germs, and I think ophthalmic surgeons are agreed as to the advisability of using antiseptic precautions and antiseptic treatment as far as practicable.

I have used the irrigation method about thirty times and the injection by the scoop-syringe forty-six times. The fluid used—distilled water previously boiled—has not caused panophthalmitis in a single instance. As to whether it may in the long run be better to use an antiseptic solution than pure water I cannot say, but am open to conviction, and after the testimony to the harmlessness of certain antiseptics borne by Dr. Wicherkiewicz and Professor Panas I am ready to try.

The immediate occlusion of the wound by an antiseptic gelatine plaster, proposed and practised by Dr. Galezowski, should be very advantageous. Besides preventing for the time—the most critical time—the introduction of germs from a diseased conjunctiva or lacrymal sac, it restores the anterior chamber, and thus allows the parts involved in the operation to come more quickly into natural relation. With the restoration of the chamber, the capsule is separated from the corneal wound, the capsule, iris, and cornea are no longer in apposition, and internal congestion from the diminution of the contents of the eyeball prevented or lessened. If it be found effectual in promoting early healing of the wound, I anticipate less adhesions of capsule and iris to wound and less internal inflammation.

Whilst ophthalmic surgeons should spare no effort to banish panophthalmitis, it is well to bear in mind that the losses from that inflammation (from 1 to 2 per cent.) are very much less than from iritis and irido-choroiditis, about which we do not write or talk so much.—Yours truly,

Belfast, Jan. 18th, 1886. WILLIAM A. MCKEOWN.

SOUTH AFRICA AS A RESIDENCE FOR CONSUMPTIVES.

To the Editor of THE LANCET.

SIR,—I have just received the following letter from an old friend who left England seven years ago with symptoms of advanced phthisis in both lungs, even to a greater extent than he himself describes; and as it contains some most instructive information for any patients who are suffering from phthisis and wish to go abroad, I have ventured to ask you to publish it *in extenso*, omitting only the personal details. Few doctors or patients appreciate that the up-country districts of South Africa can be so easily reached and have such good accommodation. I might add that Dr. Woolby who was recently drowned while bathing, also derived much benefit from living in a similar climate and following practically a similar plan of life, at Engcobo, in another inland district of South Africa.—Yours faithfully,

JOHN CURNOW, M.D.

George-street, Hanover-square, Feb. 9th, 1886.

The Convalescent Home, West Barkly, Griqualand West, South Africa, Nov. 8th, 1885.

MY DEAR DR. CURNOW,—You will probably be surprised to hear from your old demonstrator and prosector after seven years' of silence. You must think, unless you have come across my name, once or twice mentioned in THE LANCET during the last few years, that I have long ago joined the "great majority." Nevertheless, you will be glad to hear, I know, that I am in the land of the living yet, and, what is more, that I am in the enjoyment of very good—I may say, robust—health. You may remember that when I last had the pleasure of seeing you in London, when I took my final departure for this country, I was particularly ill—a cavity in my right lung, consolidation of the top of the other, combined with profuse and almost daily hæmoptysis, had reduced me to the most miserable condition. I came out here. During the voyage I was more or less ill. No hæmoptysis, but the cough and my general condition were bad. I stayed in Capetown about three weeks; it was cold and wet there, and it did not agree with me. I started to get higher up the country, and arrived in Kimberley, the capital of the diamond fields, 600 miles in the interior. There I commenced practice, and soon made a decent living. Those were good days then: few doctors and big fees. I was there six months, but the dust of the mines in those days, combined with the worry of a general practice in a large town, was not altogether suited to me. I was anything but strong. At the end of six months, my predecessor in Barkly having made what he considered a small "pile," retired and offered his practice to me. I took it and have been here ever since, more or less contented with my lot; more contented than otherwise, for the out-door country life in a splendid climate (for lungs) has made me a different individual with regard to health. I can now stand "knocking about" with most men. I can do fifty and sixty miles, and have done them frequently in a day, in the saddle. I am the Government or district surgeon of the Barkly division, about the size of a small English county, a justice of the peace for the division, and the only private practitioner. There are over twenty medical men in Kimberley, twenty-five miles off, if I should require a consultation. The town of Barkly, containing about 500 inhabitants, white and coloured, is situated on a high bank overlooking the Vaal river. The river, next to the Orange, the largest in South Africa, is a very pretty one, the banks being well lined with trees. It reminds me in some parts of its course of the Wye at home. There is plenty of fishing, bathing, boating, and shooting to be had in and on it. Most of the hills or "Koptjes" adjoining its banks contain diamonds, some of them of the most beautiful water. There is still a considerable number of diggers digging for diamonds on the Vaal, and in it when the water is low. But unless luck attends one, digging-life on the Vaal is a rather precarious existence. The climate is dry, too dry for most things but lungs. November, December, and January are very hot months——96°-98° in the shade while the sun is up; but amends is made even then by the evenings and mornings being fresh and cool. After January it begins to get cooler in the daytime each month. May, June, and July are delightful months; get frost at night; can be out all night and day.

Digitized by Google

August, September, and October are warmer but very pleasant months. But whatever the month be, the nights are cool after the hottest day, and permit of sleep. Winter nights are cold enough to make one enjoy a fire, and a big one too. We are 5000 feet above the sea. Both this district and Kimberley abound with people who tell us that they came out for "their lungs," although to look at them you would seldom guess it. They tell pitiable tales of their sufferings at home, and the helpless state in which they arrived here. They tell us that they have been so many years in the country, and that they have quite recovered. I know bankers, merchants, diggers, policemen, and all sorts and conditions of men, now well in health and doing more or less well in their businesses, who came out consumptive. I have often thought of writing to you to try and point out the advantages this part of South Africa offers to consumptives. Up to the present time, however, the difficulty of getting here was great. It was expensive, tedious, and trying to a sick person. Now this is altered. After a passage in a magnificent mail boat to Capetown, the invalid can get into a Pullman car and travel 600 miles into a splendid station in Kimberley in thirty-six hours. A coach and four will bring him down to Barkly in three hours, along a good road, if he wishes. Very different thing to the days when poor Harry Leach wrote of travelling in these parts, in an old wine-case on wheels, called a post-cart. I think the shaking he got during his hasty travels in these parts did much to shorten his days. When I came up from Capetown to Kimberley in 1878 it took me twenty-one days in a mule waggon, and a very rough time it was, in a broiling sun, through the hot sand of the desert Karroo. Now the mail trains from Capetown and Port Elizabeth rush daily into Kimberley. In 1878 the people of Kimberley lived in tin and canvas houses or huts, horribly hot and uncomfortable. Vegetables, fruit, butter, &c., were luxuries we seldom came across. I have known the humble cabbages sell for 10*s.* 6*d.* a-piece on the market, other vegetables in proportion. The late Anthony Trollope, who visited Kimberley in 1878, shook the dust from his feet and departed a sadder if a wiser man. He gave a sad description of us in his next published work. Now all things are altered. A waterworks company pumps an unlimited supply of water from the Vaal River for the use of the Kimberley people; trees and gardens are springing up all round; unlimited fruit and vegetables are brought up daily by train; people have built large and commodious houses; the town is lit by electric light; we boast of a club that costs the members some £25,000—by far the best club in the colony. In short, Kimberley is not such a bad place to live in now, but it is not exactly a good place for an invalid with "lungs"; there is still too much dust from the mines to suit irritable respiratory organs. Barkly, on the other hand, is free from dust; it is within easy distance (twenty-five miles) of the railway station, and is blessed with a fine river, which affords a means of much recreation. Further, it is very healthy in a fever and zymotic disease point of view. My business therein is "nil." Children only trouble me when they come into the world, when they cut their teeth, and when they do little things they ought not to do and suffer the consequences, riding papa's untamed steed, and getting "bucked off" with broken bones for example, or teasing the patient, and getting a dig in the ribs for their pains, &c. In Kimberley, on the other hand, the sanitary arrangements used to be shocking, consequently there was much fever. There was no railway to the sea then. Many of the fever people died down here; now most of the patients go to the sea-coast to "pick up." I live in a by no means uncomfortable house: it is a Government building, built of stone. Cool in summer and warm in winter, with good large lofty rooms, it stands about fifty yards from the river and about a quarter of a mile out of the village of West Barkly. There are eight or ten acres of unoccupied ground all round the place. I keep a sort of cross between a hospital and a convalescent home in it, that is, I have to take in acute cases, accidents, &c., from among the white population of the district, while at the same time I take in as many convalescents as possible. Last year we took in sixty-nine during the year. The Government give a grant towards [illegible] free patients; the rest are paying patients, [illegible] 6*d.* per diem, exclusive of wines and extras. If the patient is not in a hopeless state when he arrives here, he can [illegible] be guaranteed a cure by simple residence, without [illegible] or confinement; simply by fresh dry air [illegible] A patient should stay here at least twelve months, longer if possible. It took me two years to quite get rid of my cough and every vestige of expectoration, but twelve months made me quite a different man. A male patient from twelve to fourteen years of age upwards would have the best chance of getting rapidly well here. I am sure riding and driving are of invaluable assistance in aiding the damaged lungs to recover. We get an English mail and papers every week, and can obtain any amount of books from the Kimberley Public Library. There is shooting for those who can shoot. There is good coursing after buck and hare. I get good fun coursing during the winter. With regard to children, if strong enough it could be arranged for them to go on with their education for a few hours every day. There is an English church and rector (wife and family) here; a civil commissioner and magistrate, and a number of officials. Ladies from England would probably find it rather dull, as there would not be the same facilities for occupying their spare time as there are for men. The ladies here are, however, pretty active at lawn tennis, and manage generally to amuse themselves without much complaint. Patients, as a rule, have not been sent far enough up country by doctors at home. Our old family doctor in England, hearing that I was still alive, some years ago sent four patients out in consumption. They all stayed within 200 miles of the coast, where the climate is given to much rain, and consequently the air is moist, hot, and enervating; they all died. If they had come to this almost rainless part of the world I believe they might all have got better. Saloon fare to Capetown, £35; railway fare to Kimberley, first-class, £6 6*s.* I am afraid I have bored you with this disjointed letter. I commenced it in November last, and came across it again to-day, Jan. 10th, 1886. I will only point out in a condensed form what is hardly yet known to physicians in London—viz.: 1. That consumptive patients can now travel up to the driest part of the Cape Colony in the most comfortable manner. 2. That, having arrived there, they can obtain fairly comfortable and well-appointed quarters to reside in.—Believe me, ever yours sincerely,

Dr. John Curnow, London. W. R. HARRHY, M.R.C.S.

THE TREATMENT OF PERTUSSIS.

To the Editor of THE LANCET.

SIR,—At the time of writing my letter about the treatment of whooping-cough, I was not aware that carbolic acid had ever been given internally for that complaint, although I was cognisant of the fact that it had been frequently used as a remedy by inhalation; but this method, although of some use, I had never considered capable of neutralising or destroying the exciting cause of the disease, which, in my opinion, does not originate and multiply in the respiratory tract, in spite of the symptoms being mainly manifested there, but at some point in the *primæ viæ*. That this is a fact is fully proved by the result of the treatment adopted. I can account for not having seen Mr. Harries' communication of July 13th, 1878, as at that time I was travelling in the Pacific Ocean (quite a misnomer, by the bye), and my opportunities of perusing THE LANCET, I regret to say, were few and far between. I would like to add that the more I see of the effects of different kinds of treatment in disease, the greater I am impressed with the importance of prescribing antiseptics, especially in the zymotic varieties; for instance, without laying any claim to originality, I always prescribe eucalyptus globulus in röthein, chlorine in scarlatina and diphtheria, and carbolic acid in typhoid, with the most satisfactory results. I am, Sir, yours obediently,

Bournemouth, Jan. 23rd, 1886. F. W. CORY.

To the Editor of THE LANCET.

SIR,—In the year 1883 I wrote an essay, as a competitor for the Fothergillian Gold Medal of the Medical Society of London, on the Pathology and Treatment of Whooping-cough, in which I gave the results of my investigations and study of this disease, which I had been pursuing for two years previously. They were, briefly, that it is a specific disease, affecting the blood, but having the bronchial mucous membrane as its chief seat, the specific organism developing there, and infecting the blood from thence. In this view I was supported by Mr. T. Dolan. In

Digitized by Google

the paper so prepared by me I held that the only rational treatment could be local antiseptics, and recommended the use of vaporised carbolic acid. I gave in illustration some picked cases, taken from a list of more than one hundred, which had been successfully treated by this means. I do not wish to claim any priority, but simply to state facts, as above.

Yours, &c.,

Crawshawbooth, Manchester. J. L. KERR, M.B., C.M.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—I enclose a copy of a circular and petition which we are issuing to the Members of the College. May we hope for its insertion in your journal? With many thanks for the valuable aid you have hitherto given us,

I am, Sir, your obedient servant,

WM. ASHTON ELLIS, Hon. Sec.

Western Dispensary, Westminster, Feb. 5th, 1886.

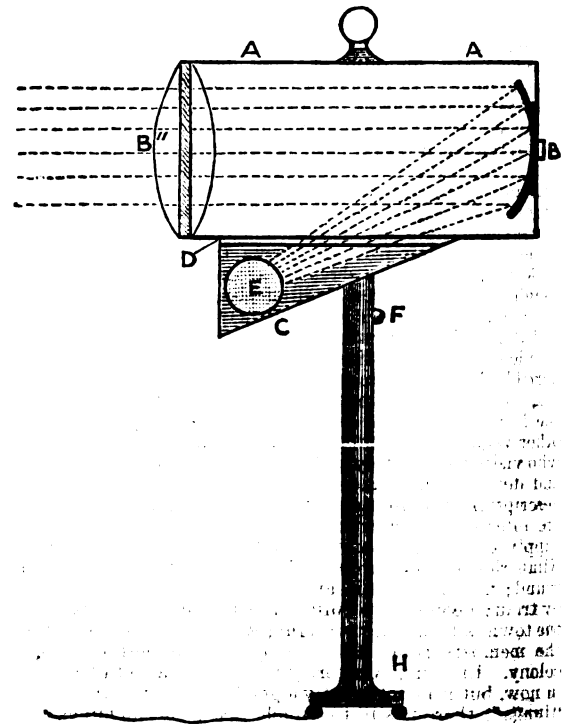
The following is the petition referred to:—

To the Queen's Most Excellent Majesty in Council.

The humble petition of the Members of the Royal College of Surgeons of England sheweth: That whereas a petition has been prepared for presentation by the President and Council of the Royal College of Surgeons of England, praying for a supplemental Charter, or alterations in the existing Charters previously granted to the said Royal College, your humble petitioners approach your Most Gracious Majesty respectfully to point out that by the present Charters the Members of the said College (who are in proportion to the Fellows as 14 to 1) have no status of any kind in connexion with the governing body.

Your petitioners most humbly submit that it would be both equitable and politic that the Members should have a voice in the conduct of a corporation of which they are, and always have been, numerically and financially the mainstay. At present the Council, elected by the twelve hundred Fellows only, deals absolutely with the interests, property, and moneys of the College, whilst sixteen thousand Members are wholly unrepresented.

Your petitioners do, therefore, most earnestly pray that before granting any Charter or supplemental Charter to the said Royal College, the present position of your petitioners may receive your Majesty's gracious consideration for such provisions as will create and secure for the Members (who so largely contribute to the prestige and welfare of the said College) the right of representation and other privileges which should belong to the members of a corporate body; further that an inquiry may be instituted into the constitution of the Council, the management of the College, the conduct of examinations, and the expenditure of the College funds.



Finally, your petitioners very humbly pray that in the event of no petition for a supplementary Charter or otherwise being presented by the Council of your Royal College, your Majesty may be graciously pleased, in your wisdom, equity, and discretion, to sanction and provide for certain alterations being made in the present existing Charter so that it may contain such provisions as are hereinafter mentioned:—1. That all Members of a certain number of years' standing, to be determined by your Gracious Majesty, may, after having been registered, conjointly with Fellows, exercise the privilege of electing the Council. 2. That a certain proportion of the Council may consist of Members. 3. That the period of office of members of the Council be considerably shortened. 4. That Members and Fellows be permitted to vote by voting papers. 5. That no fees of any kind be paid to any College fund by Fellows or Members on their election to office. 6. That the Council prepare a yearly report, together with an account of income and expenditure of the College funds duly audited by a public accountant, which after its submission for approval to the Fellows and Members (annually summoned for this purpose by the President of the College) shall, on adoption, be required to be published in the medical journals. 7. That enlarged power may be given to the Council to suspend or revoke the licence of any Fellow or Member on proof of discreditable conduct, whether professional or otherwise.

And your petitioners, as in duty bound, will ever pray, &c.

APPLICATION OF THE ELECTRIC LIGHT TO THE OPHTHALMOSCOPE.

To the Editor of THE LANCET.

SIR,—I was much interested in reading a description of Dr. Davidson's application of the electric light to the ophthalmoscope, because I had absolutely in preparation for your columns the description of an instrument which Mr. Robson, an optician of this city, is constructing for me with the same object, and which he has had in his hands for some time. As I think my instrument has some advantages over Dr. Davidson's, I send you a drawing of it, together with a description. It consists of a short tube, blackened in the interior, of telescopic construction, so that it may be elongated and contracted within certain

limits (A A). At one end (B) is a mirror of short focus, movable in its vertical diameter by a small screw. The aperture (B'') at the other extremity of the tube may be closed by tinted glasses or a bull's-eye lens. In a small triangular chamber below the tube is situated the small incandescent lamp (E), the brilliancy of the illumination from which can be moderated by inserting tinted glasses through a slit at D. The mode of action of the instrument is made obvious by the diagram. The wires pass up the handle, and electric contact is made by the button (F) when the instrument is in use. Ophthalmoscopic examinations may be made with this instrument in the daytime, by the direct method, without darkening the room. The lamp can be used for all ordinary purposes by screwing on a stand at H, and inserting a condensing lens at B''. The drawing shows the instrument a little larger than its actual size.

I am, Sir, your obedient servant,

CHRISTOPHER S. JEAFFRESON.

Saville-row, Newcastle-on-Tyne, Feb. 9th, 1886.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE LYING-IN HOSPITAL.

THE annual meeting of this useful institution was recently held, Dr. Gibson presiding. The medical officer's report showed a considerable increase in the number of patients admitted over the previous year. Including out-patients, 268 cases had been admitted, and no death had occurred.

Digitized by Google

The committee's report showed the hospital, which is a very old building, to be insanitary in many respects. A most interesting discussion took place as to the advisability of endeavouring to raise funds to build a new Maternity Hospital, with all modern improvements. It was finally decided, however, to repair the sanitary defects of the present building, and to further the scheme for erecting a new hospital. The public would no doubt make a hearty response to a call of this nature, for while the poorer population has very much increased, so also has the necessity for aid of this nature to mothers. The present accommodation is miserably deficient.

TYNEMOUTH INFIRMARY.

The scheme for providing an infirmary in the borough of Tynemouth, which includes the important town of North Shields, is making progress. A public meeting has been held, at which it was resolved that, as in June, 1887, Her Majesty will have attained the fiftieth year of her reign, preliminary arrangements be made for laying the foundation-stone of the Borough of Tynemouth Victoria Jubilee Infirmary. It was also agreed to ask the Duke of Northumberland, who is the principal land proprietor, to grant a site for the proposed building.

ELSWICK AMBULANCE CLASSES.

The great ordnance and shipbuilding firm of Sir Wm. Armstrong and Co., at Elswick, in this city, about three years ago instituted some ambulance instruction classes, which have proved to be of a highly useful and practical character, and of great benefit to their workmen. Dr. R. Clark Newton has commenced a course of lectures for the present session, and the examinations passed showed much intelligence on the part of the workmen, and reflected great credit on their instructor. Every ambulance student kept a record of the accidents attended by him during the year, and it was shown that thirty-five accidents had been attended by one man alone. It was stated at the late meeting in furtherance of the ambulance classes that 428 accidents had occurred at the works of sufficient gravity to lay the sufferers on the compensation fund, while a great number of minor accidents had taken place not necessitating help from it.

SMALL-POX IN DURHAM COUNTY.

A rather serious outbreak of small-pox has taken place at the mining and manufacturing village of Birtley, near Chester-le-Street. The cases are reported to be numerous, and some deaths have taken place. An outbreak of small-pox in the winter in a colliery district is always regarded as unfortunate, for the habits of the people favour the spread of the disease, perhaps more than in the warm weather, when thorough disinfection and isolation can be better carried out.

POISONING BY PHOSPHORUS.

Another case of phosphorus-poisoning by lucifer matches has been admitted into the infirmary, the patient this time being a married woman, who has suffered severely from drinking an infusion of lucifer matches; she is, however, likely to recover. This, I believe, makes the eighth or ninth case since this mania or epidemic first manifested itself in the north.

Newcastle-on-Tyne, Feb. 1st, 1886.

EDINBURGH.

(From our own Correspondent.)

THE LORD RECTORSHIP OF EDINBURGH UNIVERSITY.

IN the autumn of the present year the office of Lord Rector of the University will fall vacant, Lord Iddesleigh's three years' term of office having then come to an end. The office is awarded in accordance with the majority of votes given by matriculated students to the various candidates who may become competitors for the honour. In reply to an inquiry addressed to him by the Committee of the Conservative Association of the University, Lord Iddesleigh has intimated his willingness to become a candidate again should this meet the desire of the students. At a meeting of Conservative students to which this communication was made, a formal motion adopting Lord Iddesleigh as the Conservative candidate for the next election was submitted and carried unanimously. No Liberal candidate has at this early date been announced, but it is certain that a suitable name will be forthcoming within the next few months, as the Liberal students have become a much more organised party since their defeat in 1883, and are now prepared to carry on a most active contest with a very fair chance of success.

THE CHAIR OF PHYSIOLOGY IN ABERDEEN.

It is announced that two Edinburgh graduates are likely to become candidates for the Chair of the Institutes of Medicine in the University of Aberdeen, which will shortly become vacant through the translation of Professor Stirling to the corresponding Chair in the Victoria University, Manchester. Mr. H. Ashdown has acted for some years as assistant to the Professor of Physiology, and is Senior Demonstrator of Physiology in the University of Edinburgh, having previously held the post of Demonstrator of Anatomy in the University under Professor Turner. He has been for some time engaged in conducting and directing physiological and histological researches in the physiological laboratories of the University. Dr. D. Noël-Paton is also spoken of as a candidate; he holds a research fellowship from the University, and has contributed some interesting observations upon urea formation to the literature of the chemical metabolism of living tissues; he is also the author of other papers upon medical and physiological topics.

THE QUESTION OF CAP AND GOWN FOR UNDERGRADUATES.

Some months ago the Students' Representative Council, by means of a plebiscite, attempted to ascertain the views of the students generally in regard to the propriety of adopting academic costume. Although a majority of the undergraduates, who voted were in favour of the proposed change, the result was not satisfactory, as only a little over a third of the total number of matriculated students expressed any opinion in the matter. The question was referred to the Senatus Academicus, who have decided that it is not expedient to interfere with the existing usage; a decision specially important for students of the Medical Faculty, to whom the special academic garb would have proved very irksome in many respects, especially during the period of their more advanced studies, of which clinical and dispensary work forms so important a part.

EDINBURGH HEALTH SOCIETY.

Last Saturday a somewhat unique demonstration was given to the public under the auspices of this Society. In the presence of a large audience, presided over by Dr. Byrom Bramwell, a practical demonstration of sick-room cookery was carried out by ladies of the Edinburgh School of Cookery and Domestic Economy. A lecture from the pen of Miss Guthrie Wright was read, in which the principles involved were ably discussed, a number of practical illustrations detailed, and several useful recipes enumerated. During the lecture these illustrations were actually put into practice before the eyes of the audience, and the products submitted to the judgment of a committee. A great element of usefulness in the demonstration was the fact that as far as possible the utmost simplicity was observed not only in the choice of materials but in the methods of preparing them; so that in both respects a lesson was conveyed which would be applicable to the requirements of all classes of the community.

Edinburgh, Feb. 9th.

IRELAND.

(From our own Correspondent.)

IRISH LUNATIC ASYLUMS.

THE annual report of the District, Criminal, and Private Lunatic Asylums in Ireland for 1884 was only issued last week, although the report of the inspectors is dated Aug. 7th, 1885. The cause of this delay requires some explanation from those concerned in the matter, as the report is in consequence rendered almost valueless. Setting down the population of Ireland at 5,000,000, and dealing with recognised statistical facts, the inspectors assume that about 1 individual in every 350 is more or less mentally affected, and that actual lunatics, or those who at one period of life possessed clear reasoning powers, may be approximately set down at 1 in every 450, the difference for the most part being constituted of epileptics, idiots, and congenital imbeciles. In regard to this calculation, however, it should be borne in mind that a normal pro-

Digitized by Google

portion of the sane to the insane has been impaired within the past few decades by an emigration of about 1,500,000 of the healthiest of the inhabitants of this country, a fact illustrated by the present residence in poor-houses of no less than 3775 labouring under some form of mental disease, independent of the aged, infirm, and physically prostrate. Contrasting the relative population of England and Wales with that of Ireland, and the proportion of insanity as recognisable from statistics in both countries, their position appears to be analogous. England and Wales, with a population of 27,500,000, had 79,700 lunatics; while Ireland, with a population of 5,000,000, had 14,288 registered insane, or about 1 to 348. Of the 9687 patients in the district asylums, with reference to probable or possible curability, 7399 are recorded as hopeless cases, and 2288 as admitting of amelioration, if not of actual recovery.

HEALTH OF BELFAST DURING 1885.

The general death-rate has been higher than in the two preceding years, as was also the mortality from zymotic and lung affections. It was this latter increase which has so materially added to the general death-rate in this urban sanitary district. The epidemic of measles which prevailed, especially in the second quarter of the year and also in the other quarters, was very severe; and the changeable and severe weather of the spring caused many deaths from diseases of the respiratory organs and phthisis. It is, however, satisfactory to note that there has not been a single death from small-pox in the Belfast district for two years, and that typhus fever has caused fewer deaths than in either 1883 or 1884. Scarlatina has also shown a smaller mortality than in these years; indeed, had it not been for the fatal epidemic of measles the death-rate from all zymotic diseases would have been very low; but measles alone gave a rate of 2·70 out of a total of 5·3.

CITY OF DUBLIN HOSPITAL.

A fancy fair and carnival was held at the Artisans' Exhibition last week, on behalf of the City of Dublin Hospital. The attractions for the public were so many, and so well worth visiting, that enormous crowds attended on the several days the bazaar was held, and a very large sum of money was obtained for a most deserving charity.

Dr. Rawdon Macnamara has been re-elected the representative of the Royal College of Surgeons in Ireland on the General Medical Council for the ensuing year.

Sir Charles Cameron, President of the Royal College of Surgeons, who had been indisposed for some time past, is now, I am glad to state, thoroughly recovered, and is able to resume his official and professional duties.

Dublin, Feb. 9th, 1886.

PARIS.

(From our own Correspondent.)

PTOMAINES AND THE MICROBE THEORY.

THE discovery by M. Gautier of the part played by ptomaines and leucomaines in the pathogeny of disease is a terrible blow to the microbian theory, as in a paper communicated by the author to the Academy of Medicine it has been demonstrated that the non-elimination from the body of dead animal matter is the only source of all human ailments. Professor Peter has always been vehemently opposed to the bacillary theory of the etiology of disease, and looks upon the discovery of ptomaines and leucomaines as a new era in medicine. Although he himself had long ago foreseen the existence of such elements as causes of disease, it was left to M. Gautier, the eminent chemist, to formulate his theories in a more scientific manner. This new theory formed the basis of a very interesting paper read by Professor Peter at the Academy of Medicine last week, in which he makes out that this new theory of auto-infection is quite compatible with clinical observation, whereas the microbian theory is so shrouded in mystery that Koch himself had been induced to considerably alter his opinions respecting the *rôle* of the comma bacillus in the development of cholera, and now declares that the disease is caused by a ptomaine secreted by a bacillus. In concluding his paper Professor Peter made the following remarks: "M. Gautier has shown that in the dead body, and even in the living, ptomaines are formed; these alkaloids, ptomaines or leucomaines, are absolutely toxic; an auto-infection characterised by hyperthermia is the result. This theory rids us, at least for a time, of the tyranny of the microbes. If urea, which is an alkali, is constantly formed in our organism, why should there not also be formed an alkaloid in it? It is only a question of degree. Life is a contingent phenomenon; it is a series of partial deaths. It may therefore be said that we carry in ourselves while living a portion of our own corpse, but we resist the work of auto-infection by two distinct mechanisms: the elimination of the toxic substance and its destruction by oxygen. We should no longer hesitate between the parasitic doctrines, which are shrouded in dark hypotheses, and this new doctrine, which is as luminous as it is precise, which explains the phenomena of normal and abnormal life."

STATUE TO CLAUDE BERNARD.

A statue, erected to the memory of Claude Bernard, the eminent physiologist, was unveiled on Sunday last, in the presence of the Minister of Public Instruction, delegates from the Institute and University of France, amongst whom were also present MM. Paul Bert, Pasteur, Renan, and other scientific and literary men. The statue is of bronze, and considered a very good likeness, representing Claude Bernard in a pensive mood, as he was often seen in his laboratory, while he was meditating over a new problem from which he had not yet formed any positive deductions. The statue is placed at the top of the large staircase leading to the College of France, where he had worked in the laboratory for more than forty years. On one side of the pedestal is inscribed his name, with the statement that the monument was erected by his colleagues, his friends, and his disciples. Over the different emblems on the other parts of the pedestal are to be seen the names of the principal discoveries which will for ever be associated with the name of Claude Bernard: glycogeny, diabetes, vaso-motor nerves, digestive liquids, experimental medicine, general physiology, unity of life, determinism, &c. Many interesting speeches were made on the occasion, the principal of which was that of Paul Bert, one of the most intimate friends and pupils of Claude Bernard, in which, in a few neat phrases, he paid a just tribute to the memory of his former master.

Paris, Feb. 9th, 1886.

ROYAL COLLEGE OF SURGEONS.

AT an ordinary meeting of the Council of the above College, held on Thursday, the 11th inst., the report of the Building Committee of the two Colleges, the Royal College of Surgeons and the Royal College of Physicians, in reference to building on the Savoy Estate, was presented. It was approved and adopted, and authority was given to the Building Committee to make the necessary arrangements for the ceremony of laying the foundation stone. The letter from the Committee of the Association of Fellows, signed by the hon. sec., Mr. Bruce Clarke, in reference to the proposition to elect fifty Fellows yearly without examination, was read. Mr. George Robert Wyatt, of Tulse Hill, was elected a Fellow of the College.

Obituary.

JAMES BALLS WOOLBY, M.B. LOND.

MR. WOOLBY, who was accidentally drowned whilst bathing on January 1st at Groot river, Cape Colony, was a native of Halesworth in Suffolk, and received his medical education at King's College, where he entered in October, 1875. In 1876 he obtained a junior scholarship; in 1877 he passed the Intermediate M.B. Examination at the London University, taking honours in Materia Medica; in 1878 was prizeman at King's College in Forensic Medicine, Obstetrics, and Pathology, and in 1879 was elected an Associate of the College. Just as a brilliant career was opening before him his health began to fail, and an attack of hæmoptysis, accompanied by other signs of chest mischief, alarmed his friends, especially as his family history on the maternal side showed a strong tendency to consumption. He therefore took the L.R.C.P. Lond. in 1879, and after a voyage or two to the Cape, stayed in South Africa for the next two years, with

Digitized by Google

great benefit to his health. He returned in 1882 and passed the Second M.B. Examination. He was appointed physician's assistant and afterwards assistant house-surgeon, to the Bristol General Hospital, and became a M.R.C.S.Eng. in January, 1884. He was then elected resident medical officer to Queen Charlotte's Lying-in Hospital, and may be said to have been the first who systematically and thoroughly carried out the principles and practice of antiseptic surgery in that institution, with the remarkable results described by Dr. Priestley recently at the Obstetrical Society. His devotion to the duties of this hospital, the fatigue attendant on night-work, and an attempt at the same time to read for his M.D. degree, again told seriously on his health, and symptoms of rapid phthisis (high temperature, night sweats, slight hæmoptysis, and râles over the upper part of both lungs) presented themselves. He again left for South Africa, taking the medical charge of a mission-station at Engcobo, Tembuland, and had improved greatly in health and was rapidly increasing in weight, so that when he last wrote to his friends in England he spoke in the most reassuring manner as having practically recovered, and as being about to start on a hunting expedition. The news of his accidental death came as a great shock, and the regret at so early and sad a termination to his career can scarcely be expressed. Besides his medical knowledge, Mr. Woolby had much literary culture; and his unassuming manner, gentle disposition, obliging friendliness, and self-sacrificing devotion to duty will be long remembered by all with whom he came in contact.

R. ROBERT MADDEN, F.R.C.S.

ON the 5th inst., at Booterstown, near Dublin, the death occurred of Mr. Richard Robert Madden, formerly Colonial Secretary of Western Australia, and Secretary of the Irish Loan Fund. The deceased, who was the youngest of twenty-one children, was born in Dublin, and was admitted a Member of the Royal College of Surgeons of England in 1829, obtaining the Fellowship of that body in 1855. In 1833 he was appointed a special magistrate in Jamaica, and in this capacity he became a friend of the slaves, earning throughout the island the reputation of being their protector and sympathiser, and an ardent colleague of Clarkson, Wilberforce, and Buxton in the movement for the abolition of slavery. The esteem in which he was held by the black population was recognised in 1836 by his appointment as superintendent of liberated Africans at Havannah under the British Colonial Office, and in this post he rendered valuable services to the cause of the slave. Three years later, in 1839, he was appointed Acting Judge Advocate of the Mixed Commission Court under the Foreign Office. So highly did the Home Government regard his services in this capacity that in 1841 Lord John Russell appointed him a Commissioner of Inquiry on the West Coast of Africa, and it was whilst performing the duties of this office that his vigilance unmasked what became known at the time as the "pawn system," which turned out to be slavery in all respects carried on under the very eyes of the British authorities and of the officials entrusted with the protection of the negroes. In 1847 Mr. Madden was appointed Colonial Secretary of Western Australia, a post which he retained for three years until he became Secretary to the Irish Loan Fund. This position he resigned some years ago, and devoted the remainder of his life to literature. Mr. Madden was the author of the following, amongst other, works: Infirmities of Genius; Lives and Times of the United Irishmen; Connexion of England with Ireland; Phantasmata, or Illusions and Fanaticisms; Galileo and the Inquisition; and the Life and Times of Savonarola. The works published by him relating to Ireland were contributions to the study of the Irish question of the period, and may still be referred to with profit. At the time of his decease Mr. Madden was in his eighty-eighth year.

ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.—At the annual meeting of the subscribers to this institution on the 9th inst., it was stated that the excess of income over expenditure for the past year was no less than £1723, whilst in addition to this, legacies and special donations amounting to £644 were received. The number of in-patients was 591, and 2247 out-patients received advice. The satisfactory financial state of the hospital is attributed to a canvass made early in 1884 with the object of obtaining increased support for the institution.

Medical News.

UNIVERSITY OF LONDON.—The following candidates have passed the recent Preliminary Scientific (M.B.) Examination:—

ENTIRE EXAMINATION.

FIRST DIVISION.

Clutterbuck, Medwin Caspar, University College, Bristol.
Krohn, Ronald E. S., Univ. Coll. and School, and private tuition.
Lansdown, Charles Bebank, University College, St. Mary's Hospital, and private tuition.
Mack, Cyril Gordon, St. Mary's Hospital and private tuition.
Macnamara, John Joseph, Univ. Edin. and Univ. Coll., London.
Snell, Sidney Herbert, University College and private tuition.

SECOND DIVISION.

Atwool, William Tillinghast, University College, St. Mary's Hospital, and private study and tuition.
Cole, Robert Henry, St. Mary's Hospital.
Edge, Arthur James, Owens College, St. Bartholomew's Hospital, and private tuition.
Heath, Alan Jasper, Univ. Coll. and private study and tuition.
Murrell, George F., University College, St. Bartholomew's Hospital, and private study.
Paul, John Ernest, University College and private tuition.
Price, Arthur Edward, St. Thomas's Hospital.
Taylor, F. Ryott P., Westminster Hospital and private study.
Thorne, Attwood, St. Mary's Hospital and private tuition.
Worsley, Reginald Carmichael, University College.
Wright, Sydney Faulconer, St. Thomas's Hospital.

At the January Matriculation examination of the University, 104 candidates passed in the Honours division, and 315 and 27 in the first and second divisions respectively. Samuel Arthur King gained the exhibition of £30 per annum for two years; W. T. N. Spivey the exhibition of £20 per annum for two years; and E. G. Hawke the exhibition of £15 per annum for two years.

SOCIETY OF APOTHECARIES.—The following gentleman passed the examination in the Science and Practice of Medicine, and received a certificate to practise, on the 4th inst.:—

Henderson, James Threapland, Wibsey, near Bradford.

On the same day the following passed their Primary Professional Examination:—

Charlesworth, George, Middlesex Hospital.
Mason, Francis John Gorringe, St. Bartholomew's Hospital.

THE annual meeting of the St. Mary's Hospital for the treatment of diseases of women and children, Manchester, was held on the 8th inst.

A MEETING held at Eastbourne on the 5th inst. decided, subject to obtaining the necessary land at a moderate cost, to enlarge the Princess Alice Memorial Hospital.

HER Majesty has forwarded a donation of £100 to the Countess of Dufferin's Fund in support of the National Association for supplying Female Medical Aid to the Women of India.

AT an inquest recently held at Upton on the body of James Hunter KNOX, M.B. Glas., whose death was caused by morphia, the jury returned a verdict of suicide whilst temporarily insane.

THE eighteenth annual dinner in aid of the funds of the French Hospital was held on the 6th inst. During the evening subscriptions amounting to about £2000 were announced.

THE committee of management of the Aberdeen Royal Infirmary on the 27th ult. resolved that the treatment of zymotic diseases—except typhoid fever—be discontinued at the earliest practicable date.

A CONFERENCE on the subject of the management of idiots is to be held in Gratz from the 6th to the 8th of August. A conference on the statistics of idiocy has just been held in Pesth.

MEDICAL MAGISTRATES.—The Lord Chancellor has appointed Dr. Douglas A. Reid and Mr. John Griffith Lock, M.A. Cantab., M.R.C.S., to the Commission of the Peace for the Borough of Tenby.

ROYAL FREE HOSPITAL.—The fifty-eighth annual meeting of the governors of this institution was held on the 4th inst. The report of the committee of management showed that the receipts from all sources during the past year amounted to £7556, and the total expenditure to £11,275. During 1885, 1728 in-patients had been admitted, and the daily average of patients in the wards was 135. The number of out-patients under treatment was 21,853.

Digitized by Google

THE fifth annual meeting of the Sanitary Assurance Association was held on the 8th inst., when a highly satisfactory report was presented by the committee.

VACCINATION GRANTS.—The following gentlemen have received the Government grant for efficient vaccination: Mr. B. J. Lee, North Wingfield District, Chesterfield Union (fourth time), and Mr. P. Butler-Stoney of the Millom District, Bootle Union, Cumberland (fifth time).

DR. JOHN BURNESS, late of Montrose, was drowned last week while crossing Lockgoil in a small boat to visit a patient. The deceased, who was between sixty and seventy years of age, was highly esteemed throughout the district in which he resided.

IN the Swiss Universities there are during the present semester 650 medical students—207 in Zurich, 198 in Berne, 124 in Geneva, and 191 in Basle. Of these, 78 are women. In Berne there are 63 foreign students, of whom 41 are women.

A HAMBURG court of justice has sentenced a medical man to a fine of £15 for "careless damage" to a woman who was suffering from hæmorrhage, and on whom he had employed a "doubtful treatment" without examining her or attempting mechanical treatment.

WINDSOR ROYAL INFIRMARY.—At the recent annual meeting of the subscribers to this institution it was reported that the new ward, replacing the Hibbert Ward, had been completed, and that extensive sanitary works had been carried out and additions made to the furniture of the wards, the whole involving a total extra expenditure of about £1500.

ST. MARK'S HOSPITAL.—The fiftieth annual report of the committee of management of this institution was laid before the governors on the 11th inst. The total receipts amounted during 1885 to £3902, a sum which exceeded the expenditure by £429. During the year 310 in-patients passed through the wards of the hospital, a number much in excess of any previous year.

CONVALESCENT HOME.—A convalescent home for hospitals and the better class of mechanics and small tradespeople has recently been established by a benevolent lady from philanthropic motives on the outskirts of Lewes. The home, which is only for the reception of women and girls over nine years of age, contains six beds, and the weekly charge ranges from five to eight shillings.

CHARING-CROSS HOSPITAL.—The annual court of the governors of this hospital was held on the 10th inst., when the sixty-fifth yearly report was read. It stated that during the past year there were admitted 1584 in-patients and 22,615 out-patients. The total receipts for the year, including legacies, were £2154, as against £4231 for 1884; and the expenditure amounted to £12,775, against £12,663 for the preceding year.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.—At the annual general meeting of the governors of this institution on the 10th inst., it was reported that the number of in-patients admitted during the year had been 1011, as against 900 in 1884, and the number of out-patients was 15,924, being an excess of 413 over the preceding year. The total receipts were £8133, and the excess of expenditure over income was £1420.

EXPLOSION AT A HOSPITAL.—A serious explosion is reported to have occurred on Wednesday night at the Southport Convalescent Hospital. The heating apparatus was undergoing repair, and the stoker had only a few minutes before left the building, after making up the fire, when the boiler exploded, doing considerable damage. Fortunately, at the time all the patients and officials were in another wing of the building and escaped injury.

MANCHESTER CLINICAL HOSPITAL.—From the medical report which was read at the annual meeting in connexion with this institution on the 8th inst., it appears that the number of patients admitted during 1885, including women and children, was 7108, being an increase of 258 on the previous year. The number of consultations in the out-patient department amounted to 27,877, or 1877 more than in 1884. The expenditure of the hospital is about £300 in excess of the ordinary income.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—At the next quarterly meeting, to be held at Bethlem Hospital, St. George's-road, S.E., on Wednesday, 24th inst., at 4 P.M., Dr. Mickle will read a paper on "Some Abnormal Forms of Breathing." The members of the Association will dine together at the Holborn Restaurant, High Holborn, at 7 P.M.

WESTMINSTER OPHTHALMIC HOSPITAL.—Amongst the cases exhibited at this hospital on the clinical evening, Feb. 5th, were—Albuminuric Retinitis, Syphilitic Hyalitis, Optic Neuritis, Retinal Hæmorrhages, Pigmentary Retinitis, Choroiditis, Myopic Changes in Fundus, Embolism of Arteria Centralis, Detachment of Retina, and Chronic Glaucoma with Cupping of Optic Discs.

HOSPITAL SATURDAY FUND.—Mr. Robert Frewer, secretary of the Hospital Saturday Fund, has just received the following from Henry Lane, Canterbury, New Zealand:—"Sir,—Enclosed is a Bank order for £100 towards the funds of the hospitals. We hear in this far away country of the distress and sickness among the poor in the metropolis, and as an old resident in London I beg you to accept this towards the relief of the distressed."

CITY OF LONDON TRUSS SOCIETY.—The annual general meeting of the governors of this Society was held on the 3rd inst. The total income of the past year from all sources amounted to £5062, and the total expenditure to £5594. The number of patients relieved in 1885 was 9000, bringing up the total number treated since the foundation of the charity in 1807 to 413,316. The annual festival dinner is to be held on the 25th inst., and the Lord Mayor has promised to preside.

OLD STUDENTS' FESTIVAL IN ST. PETERSBURG.—The students who qualified at the St. Petersburg Medico-Chirurgical Academy in 1860 have recently celebrated the twenty-fifth anniversary of their entry into professional life. They not merely commemorated the occasion by a dinner, but they have published a book setting forth the scientific professional work and giving to some extent a series of biographies of the former fellow-students. The figures given are instructive. The number of would-be students who attempted to enter the Academy in 1855 was 600, of whom only 350 were accepted. Of these, 142 qualified in 1860, and at the present time only 96 of these are left, all of whom, it is stated, enjoy a good reputation in medical and scientific circles.

SEWER VENTILATION.—A patent has recently been taken out by Mr. Malvin of Harrogate for a method for exhausting gas from sewers, and for consuming or deodorising and dispersing of such gas. The plan provides for the division of a town's sewers into sections by the fixing of automatic doors. The sections are to be isolated, and each furnished at a suitable spot with a chimney or shaft and a furnace, which shall be as nearly as possible smokeless. An upcast shaft from the sewer is to be connected with the ashpit under the furnace, which is in the form of a cloud chamber. After passing through the fire the gas is conducted to a reservoir, where it encounters a spray of water designed to lay any solid particles which may have been produced by the action of the fire, so as to prevent their emission into the atmospheric air. The sewer gas, after passing through the fire, is taken by the current up the chimney and delivered at a considerable altitude above the street.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BARKER, WILLIAM J. T., L.R.C.P.Lond., M.R.C.S., has been appointed **Medical Officer** for the Churchstanton District of the Taunton Union.

BODY, HENRY MARTEN, M.R.C.S., L.S.A.Lond., has been appointed **Medical Officer of Health** for the Crediton Urban Sanitary District, vice Heygate.

BROWNE, OSWALD, M.A., M.B.Cantab., M.R.C.P., has been appointed Honorary Physician to the St. Marylebone General Dispensary, vice P. M. Chapman, M.D., resigned.

BUIST, J. B., M.D., F.R.C.P.Edin., has been appointed by the Local Government Board a Teacher of Vaccination in Edinburgh, vice J. O. Affleck, M.D., F.R.C.P.Edin., appointed a Physician to the Royal Infirmary.

CARTER, R. BRUDENELL, F.R.C.S., has been appointed Ophthalmic Surgeon to the National Hospital for the Paralysed and Epileptic.

COOPER, JOHN N., M.K.Q.C.P.I., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Fourth District of the Risbridge Union.

GARDNER, HENRY WILLOUGHBY, M.R.C.S., L.R.C.P., has been appointed Junior House-Surgeon to the Liverpool Children's Infirmary, vice R. R. Whishaw, M.B.Cantab.

GUNN, R. MARCUS, F.R.C.S., has been appointed Ophthalmic Surgeon to the National Hospital for the Paralysed and Epileptic.

HORSLEY, VICTOR A. H., M.B., F.R.C.S., has been appointed Surgeon to the National Hospital for the Paralysed and Epileptic.

IRVING, GEORGE B., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Stanmore District of the Hendon Union.

JOHNSON, RAYMOND, M.R.C.S., late House-Physician to University College Hospital, has been appointed Obstetric Assistant to that institution.

LORRAINE, H. J. B., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the High District of the Longtown Union.

LUCY, REGINALD H., M.B., C.M.Edin., has been appointed House-Surgeon to the London Hospital, E.

NAYLOR, JOHN H., L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Fourth District of the North Bierley Union.

NEWCOMBE, FRANK, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Wilsford District of the Sleaford Union.

SALTER, JOHN R., M.B.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Third District of the Tonbridge Union.

SERJEANT, GEORGE, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the Launceston Rural Sanitary District, vice Williams.

SMITH, T. F. HUGH, F.R.C.S., L.S.A.Lond., has been appointed Poor Law Medical Officer and Medical Officer of Health for the Third District of the Dartford Union, vice W. R. Ashurst, M.D., M.R.C.S., resigned.

SUNDERLAND, SEPTIMUS, M.D., L.R.C.P., M.R.C.S., has been appointed Resident Medical Officer to the Chelsea Hospital for Women, Fulham-road, S.W., vice Dr. Simmons, resigned.

WALLIS, A. W., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Temporary School at Harold Court of the St. Leonard (Shoreditch) Parish.

Births, Marriages, and Deaths.

BIRTHS.

BROWN.—On the 26th ult., at Litherland, Penang, the wife of W. Carnegie Brown, M.D., of a daughter (stillborn).

CABLE.—On the 9th inst., at Royal-hill, Greenwich, the wife of G. H. Cable, M.R.C.S., of a son.

CANTLIE.—On the 6th inst., at Suffolk-street, Pall-mall, the wife of James Cantlie, M.A., M.B., F.R.C.S., of a son.

DOBSON.—On the 9th ult., at Bangalore, the wife of Surgeon-Major A. F. Dobson, M.B. (prematurely), of a daughter.

GUINNESS.—On the 3rd inst., at Bampton, North Devon, the wife of T. A. Guinness, M.R.C.S., of a son.

HUME.—On the 20th ult., at Islington, the wife of F. H. Hume, M.R.C.S., of a son.

PENFOLD.—On December 20th, at Sandhurst, Victoria, the wife of Oliver Penfold, M.R.C.S., L.S.A.Lond., of a son.

MARRIAGES.

CAMPBELL—DUMACHIE.—On the 3rd inst., at Glenbolg, Lanarkshire, by the Rev. James Morison, D.D.Glas., S. George Campbell, M.B., M.Ch.Edin., M.R.C.S.Eng., of Victoria, co. Natal, to Margaret Wyllie, daughter of James Dumachie, Esq., of Glenbolg.

HILLS—FLETCHER.—On the 10th inst., at the Parish Church, Deeping St. Nicholas, Augustus Phillips Hills, M.R.C.S., of Carlton House, Battersea-park, S.W., son of the late George Hills, M.D., F.R.C.S., to Lizzie J. Holland, younger daughter of the late John F. Fletcher, M.R.C.S., and Niece of John W. Holland, of The Shrubbery, Deeping St. Nicholas.

TRAILL—ANDERSON.—On the 4th inst., at Glenburn Hall, Jedburgh, by the Rev. Robert Stewart, B.D., Minister of Jedburgh, assisted by the Rev. John Gordon Smith Napier, M.A., Minister of Kelso, Cecil Grahame Traill, M.B., C.M., Edinburgh, to Mary M'Ghie, eldest daughter of Charles Anderson, Solicitor, of Jedburgh.

TROTT—LEE.—On the 4th inst., at St. Luke's, Headless-cross, Warwickshire, by the Rev. F. Lacon, Rector, Dudley C. Trott, B.A., M.B., B.C.Cantab., of Bermuda, to Florence, youngest daughter of the late James Lee, of Greet House, Birmingham.

DEATHS.

BURTON.—On the 10th inst., at Lee Park Lodge, Blackheath, John M. Burton, F.R.C.S., in his 70th year.

CHURCH.—On the 1st inst., at Rodwell Lodge, Weymouth, William John Church, F.R.C.S., formerly of The Circus, Bath, in his 88th year.

CORTIS.—On December 27th, at Carcoar, N.S.W. (suddenly), Herbert Liddell Cortis, M.R.C.S., aged 28.

JONES.—On the 20th ult., at Strefford House, Sutton, Surrey, Robert Jones, M.R.C.S., L.S.A.Lond., of Strefford, Craven Arms, Salop, aged 80.

MADDEN.—On the 5th inst., at Vernon-terrace, Booters-town, Dublin, Richard Robert Madden, F.R.C.S.Eng., formerly Colonial Secretary, Western Australia, and Secretary to the Loan Fund Board, in his 88th year.

MATHEW.—On the 6th inst., at Eastbourne, James Edward Mathew, F.R.C.S., aged 67.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, February 15.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Charles Stewart: On the Organs of Hearing.

SOCIETY OF ARTS.—8 P.M. Prof. F. Guthrie: Science Teaching (Cantor Lecture).

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Dr. Maguire: Case of Dystrophy of the Thumb-joints.—Messrs. Francis Mason and Hurry Fenwick: Case of Excision of the Elbow after Operation followed by Tubercular Testis.—Mr. Spencer Watson: New Instruments for the Removal of Nasal Polypi.—Dr. Radcliffe Crocker: Cases of Pityriasis Circinata and Tuberculated Leprosy.—Mr. John H. Morgan: Case of Congenital Constriction by Band producing Perforating Ulcer of the Foot in an Adult. Living Specimens at 8 P.M.

Tuesday, February 16.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. Charles T. Newton: The Unexhibited Portion of the Greek and Roman Sculptures in the British Museum.

STATISTICAL SOCIETY.—7.45 P.M. Dr. William Ogle: Suicides in England and Wales in relation to Age, Sex, Season, and Occupation.

SOCIETY OF ARTS.—8 P.M. Dr. Robert James Mann: The Present State of the Colonial Possessions of Great Britain.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Drs. Moxon, Beevor, and George Ogilvie: Cerebral Tumours.—Dr. Hale White: Thinning of Skull from Cerebral Tumour.—Dr. Carrington: Cancer of Body of Stomach.—Mr. J. Hutchinson, jun.: Cylindrical Cancer of Humerus.—Mr. C. J. Symonds: Syphilitic Hepatitis and Pneumonia in an Infant.—Mr. Stephen Paget: Dermoid Cyst of Tongue.—Mr. Clutton: Epithelial Tumour of Skin near the Rectum.—Dr. S. West: (1) Aneurysm of Aorta and Aortic Valves; (2) Abscess of Gall-bladder (card).—Mr. D'Arcy Power: Multiple Intussusception.—Dr. Hadden: (1) Intestine in Lymph-adenoma; (2) Malignant Disease of both Suprarenals (cards).—Dr. Turner: (1) Syphilitic Ulceration of Trachea; (2) Conjoined Kidneys and Unicorn Uterus (card specimens).—Mr. J. Poland: (1) Amputation Stump at Knee-joint; (2) Dislocation of Knee-joint (card specimens).—Mr. E. H. Fenwick: Atresia (? Congenital) of Orifice of Ureter, Cystic Kidney (card).

Wednesday, February 17.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Charles Stewart: On the Organs of Hearing.

SOCIETY OF ARTS.—8 P.M. Prof. George Forbes: Some Points in Electrical Distribution.

Thursday, February 18.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

PRESCRIBING BY TELEGRAPH.

ACCORDING to an American contemporary, a great number of the operators in the chief office of the Western Union Telegraph Company, New York, are graduates in medicine or medical students who are thus working their way through college. Occasionally, as in the following instance, they have an opportunity to use their professional knowledge to good advantage. One of them recently had his attention attracted by the terms of a message which was being received in the office in which he was employed. It was to the effect that a certain physician was wanted at a place three miles away, to attend a young person who had just swallowed an ounce of laudanum. The student operator at once asked for all the particulars, and on receiving them a consultation was held at the office. It was decided that it would be hazardous to postpone treatment until the medical man to whom the message was addressed could be found and he had driven three miles to attend a patient in so dangerous a condition. The operators therefore ordered by telegraph that powerful emetics should be administered, suggesting home-made ones, after which the patient was to be rubbed and whipped with switches. The order was carried out, and with successful results. The physician arrived an hour later; but his attendance would have been useless had the interval been wasted.

Mr. Habgood.—We do not see in the Medical Register or Directory the name and address of the person whose testimonial is referred to.

Cosmopolitan.—No.

Mr. Thos. Ellis.—Our correspondent is the best judge of the exact fees he should charge. These should depend upon the means of his patient and his estimate of the value of his own time and skill. The fees he mentions are, in the abstract, too small for such services as those described.

THE COLLEGE OF PHYSICIANS' LIST.

To the Editor of THE LANCET.

SIR,—Placing the College list of this year (1886) along with some of its predecessors, I notice that, of 1836, and turning to its pages observe that of its 462 members (all told) there remain on the present year's list but seventeen—viz., four Fellows who were Fellows in 1836, one Fellow who was then a candidate, five Fellows who were inceptor candidates, two Fellows who were licentiates, three members, and two licentiates since 1833–34. Many considerable names of our time appear not on either list, having come and gone between these two dates. Yet will they and their work be remembered without reverting to the intervening lists. Such were Baly, Bence-Jones, Bird, Parkes, Peacock, Sibson, Tyler Smith, Brinton, Murchison, Fagge, and others. The censors for 1836 were Paris, Chambers, Holland, and Richard Bright—in the sixteenth year of Sir Henry Halford's presidency.

I am, Sir, yours truly,

Feb. 9th, 1886. C. H.

THE MEDICAL ASPECT OF THE PROVIDENT DISPENSARY SYSTEM.

IN a letter in the *Pendleton Times and Reporter* "Justitia" complains of the working of the Provident Dispensary Scheme in Manchester and Pendleton, especially since the wage-limit of membership was abolished, and families are admitted whose united earnings amount to pounds a week. It is clear that such families have no claim on medical attendance for a penny a week and a penny each bottle of medicine, as in the Manchester Scheme, which, according to "Justitia," left the medical man, after payment of expenses, about fourpence per visit and consultation. We have long endeavoured to show that by such a system the profession is injured more than by the occasional gratuitous relief of the humble class of work people at hospitals.

Mr. W. Fraser (Ashburton).—Yes. But we cannot promise insertion of every paper.

"PEAT SMOKE AND PHTHISIS."

To the Editor of THE LANCET.

SIR,—With reference to your correspondent's inquiry on this point in your last issue (p. 236), and to your editorial note in reference to the same, will you allow me to point out, on the authority of Hollinshed as quoted by Lord Lytton ("The Last of the Barons," Routledge's ed., p. 192), that "not one of the houses in England could boast a chimney in 1468; but the smoke from the single fireplace in each, after duly darkening the atmosphere within, sent its surplusage lazily and fitfully through a circular aperture in the roof. The smoke was considered good both for house and owner; the first it was supposed to season, and the last to guard from rheums, catarrh, and poses." Describing a later period of our history—viz., the reign of Elizabeth—Mr. Green says ("A Short History of the English People," p. 615) that "the chimney corner, so closely associated with family life, came into existence with the general introduction of chimneys, a feature rare in ordinary houses at the beginning of this reign." If we may judge from Macaulay's famous third chapter, this "feature" would scarcely appear to have graced all our houses during the whole of the era of the Stuarts, and we know that the plague visited this country more than once during that same era. Every scholar is familiar with Erasmus's famous description of our "filth"—a filth which Hecker calls (p. 214) "truly Scythian"—in the time of Henry; and Hallam expressly tells us that the Spaniards who accompanied Philip to England in 1554 were never tired of saying that "these English have their houses of stick and dirt, but they fare commonly so well as the king." Very similar testimony as to the "filth" of Edinburgh, Glasgow, Paris, &c., might be adduced out of Howell's Familiar Letters, Smollett, a book called "Varia," and especially from Beckman's History of Inventions; but though other diseases are mentioned as prevailing in these places, or during these periods, nothing is said specially about phthisis. Turf (*alias* peat) was when I was a boy almost the only fuel used in the south of Ireland. It is still, I believe, the principal fuel in Connaught, as well as in the Highlands and Hebrides; and I am not aware that the registrars of these countries regard this disease as non-existent in either of them. I believe, in short, that peat smoke is no more antagonistic to phthisis than is cow-dung or other "odour" of that kind; but high altitudes have ever conduced to a supple limb and a vigorous frame, and "an ample supply of *pure* [mountain] air is everywhere the great prophylactic."

I am, Sir, your obedient servant,

Auriol-road, W., Feb. 7th, 1886. WM. CURRAN.

THE SICKNESS AND ACCIDENT ASSURANCE ASSOCIATION, LIMITED.

To the Editor of THE LANCET.

SIR,—My attention has been called to an article which appeared in your columns a few weeks ago regarding a circular issued by this association to one leading medical man in every populous place in England and Scotland. To the remarks made in that article you will perhaps kindly permit me to make a reply. Our circular described the fees as utterly inadequate, mentioned the circumstances under which they were offered, and at the same time asked the opinion of the medical men to whom it was sent regarding them under those circumstances. It may interest your readers to know how the circular was received by the profession. Not taking into account those who from death, removal, or retirement were unable to act, the number who write approving can only be expressed by four figures. The number who disapprove is under twenty, the proportion thus being as ever fifty to one. Upon the circumstances themselves I will not dilate—such as the fact of this not being a life office, as described in your article, and therefore not to be compared with such an institution, the smallness of our quarterly premiums (many of them under ten shillings), the inadequacy of the remuneration of all the officials during the first twelve months, the promised increase in a few months, and the fact that in connexion with claims our appointment will continue to bring work, which in the case of a life office ceases with the examination. Without entering upon these, I may be permitted to say that the good-will thus expressed towards the association by what I think I am fairly entitled to call the entire medical profession has been to the directors gratifying in the extreme. I may also be allowed to express the hope that those who have borne the burden and heat of the day, and have for a few months acted for remuneration so inadequate, will ere long reap the reward by the appointment turning out, with increasing business and increasing fees, all that their and my own best hopes can wish.—Yours faithfully,

Edinburgh, Feb. 6th, 1886. J. B. BLACK, Manager.

"THE CONNEXION BETWEEN THE PAROTID GLANDS AND THE GENERATIVE ORGANS."

To the Editor of THE LANCET.

SIR,—I had a case a few years ago closely resembling the first of the cases described by Dr. Cribb in your issue of Jan. 30th. The patient, a gentleman aged eighty, had some prostatic enlargement; and as there was a fair amount of "residual" urine after micturition, it was decided, in consultation with Sir Prescott Hewett, that a flexible catheter should be used night and morning. The patient bore the treatment well for a couple of months, when, from a real or fancied inability to pass urine in the afternoon as he had been accustomed to do, he insisted, against my advice, on having the catheter passed three times a day, sometimes oftener. After about a week of this treatment his bladder began to show symptoms of irritability, and I was summoned to him early one morning in consequence of a sharp rigor which he had had about daybreak. I found his temperature 100·4°, and he complained of stiffness about the jaws. About noon on the same day his right parotid began to swell, and was acutely painful to touch. The swelling rapidly increased, and as the patient's frame was already much enfeebled, he sank from pyrexia and consequent exhaustion within forty-eight hours from the initial rigor. This was certainly not a case of "mumps" from contagion; but was it septic or metastatic parotitis? I may add that throughout there was no pus (visible to the naked eye) in the urine.

I am, Sir, your obedient servant,

Piccadilly, Feb. 4th, 1886. T. BROWNE O'CONNOR.

Mr. W. J. Merlin.—Our correspondent will act kindly in paying the visits and being in readiness to give any advice or help he can. He will, of course, make it clear that he is in no way responsible for the use of a secret remedy.

HYDROPHOBIA; A PLAN OF TREATMENT PROPOSED.

To the Editor of THE LANCET.

SIR,—As deaths from this terrible disease are now daily occurring, I shall be obliged if you will, with your usual kindness, allow me to place before your readers a plan of treatment which involves no risk to the patient, and which I devised some time ago, but as yet have had no opportunity of carrying into practice and so testing its value. To put the plan as concisely as possible, I shall merely confine myself to the principles involved. They are: (1) To alleviate the spasms by inhalations of oxygen, administered, if necessary, through a tracheal opening, at the ordinary (or slightly increased) atmospheric pressure; (2) to eliminate the poison of the disease by subcutaneous injections of pilocarpine; (3) to support the patient's strength by peptonised nutrient enemata; (4) if necessary, to supply the loss of the watery constituents of the blood, due to the action of the pilocarpine, by hypodermic injections of warm saline solutions, to which chloral hydrate may be added according to circumstances; (5) to destroy the virus (?) and at the same time ward off any impending attack of asphyxia by hypodermic injections of ozonised ether.

I am, Sir, your obedient servant,

January 11th, 1886. G. C. P.

THE GUARDIANS OF THE SKIPTON UNION.

To the Editor of THE LANCET.

SIR,—About eighteen months since I was elected medical officer to the Grassington district of this union, extending over an area of 22,600 acres, in which there are about twelve thinly-populated and widely-scattered villages (some of them six miles distant), at a salary of £16 a year. Finding that this salary was not nearly sufficient to pay the working expenses, I applied for an increase, which application was not entertained, and I in consequence resigned the appointment. The guardians, being of opinion they could easily obtain some other fully qualified medical practitioner to do the work at that salary, inserted an advertisement in the public journals holding out delusive hopes as an inducement for someone to accept it. Strange to say, there are several applicants from Ireland and Scotland, as usual, one of whom no doubt will be elected to the valuable appointment; but what additional income he expects to make goodness knows, as the district contains only a poor population of about 1400. What is our profession coming to?

I am, Sir, yours truly,

THE PRESENT RESIDENT MEDICAL OFFICER.

Grassington, Yorkshire, Feb. 9th, 1886.

"MORTALITY IN THE MEDICAL PROFESSION."

To the Editor of THE LANCET.

SIR,—In your issue of to-day (p. 201) you give an abstract of an excellent paper by Dr. Ogle on the mortality in the medical profession, and an able leader on the same (p. 211). There is one point that I do not think too much stress can be laid upon. It is the fact that in regard to phthisis and diseases of the respiratory organs the medical profession compares very favourably with other classes. Many medical men hold that phthisis is infectious. If it were so, would it not be much more common in members of the profession who attend upon the sick, as it is in the case of other infectious disorders, such as typhus, scarlatina, &c.? I consider the fact of its not being so of far more value than a few alleged cases of phthisis being communicated from husband to wife, or *vice versâ*. The small number of the latter can easily be explained on the ground of being a mere coincidence, just as one might find cases in which both man and wife suffer from rheumatism, which no one asserts to be infectious.

I am, Sir, yours faithfully,

January 30th, 1886. W. B.

SEA-SICKNESS.

MR. GOSTLING, F.R.I.B.A., writing from Alexandria, states that he has found the following measures useful to those troubled by sea-sickness. Little or nothing should be eaten on going on board, and the sufferer should retire to his cabin and lie head to bow, if possible, before the boat gets into rough water. By the adoption of these precautions, Mr. Gostling states that in the majority of cases sea-sickness will be avoided altogether, while in the few exceptional cases its ill-effects will be greatly modified, and a speedy recovery assured. If the berth is transverse, the occupant should lie with the head towards the centre of the ship.

G. C.'s letter deals with an important matter, but we cannot open a discussion upon it.

Mr. H. M. Gardner.—Bureaux de la Semaine Médicale, 16, Avenue de Lamotte-Piquet, Paris.

Mr. Allison (New York).—We cannot exchange.

THE THREE TOWNS FRIENDLY SOCIETIES MEDICAL INSTITUTION.

To the Editor of THE LANCET.

SIR,—Your article upon the above subject is so full of inaccuracies, that we are compelled to correct some of the statements contained in it. We have never desired to work our medical officers as horses or as any other quadruped; we have always recognised that their position is a very responsible one, and sought to relieve them from any approach to over-pressure when such appeared likely. We sought the advice of our two residential doctors as to the best means of providing additional medical assistance. They advised the engagement of two consulting doctors, one at each dispensary; Dr. Keily advising that the salaries should be £100 per annum each. We considered the matter, and resolved to engage for twelve months one consulting officer only at £150 per year, which amount we increased to £180 after six months' trial. We have tried the experiment for one year, and that experience has taught us that our wisest course is to engage two consulting officers as first advised by our residential doctors. We do not, however, believe that Dr. Keily's estimate is either fair or generous as to the salaries. His position is equal to a private practice of over £400 a year. We therefore decided to give £150 as a salary to each of the consulting doctors. Respecting the cab hire, your statements are simply ridiculous. We have never required any such preposterous explanations from Dr. Keily about his cab hire as you name. If you had read the correspondence in the *Western Daily Mercury* a short time since on the whole subject, you would have learned that we were quite willing to provide any necessary cab hire; our objection was expressed against a lavish expenditure by Dr. Keily, which the working of the Devonport district (where the work has been heaviest) proved to be extravagant beyond excuse. We therefore determined to increase the salaries of the residential doctors, the engagement of the two consulting ones relieving them of the work at the dispensaries, so that they shall in future, except in severe epidemics, pay for their own cab hire. Dr. Keily offered, if we engaged two consulting officers, to provide his own cab hire for £20 per annum. We have engaged the two consulting officers as wished, but have given £50 per annum extra, instead of the £20 which he named. Your knowledge of our local geography appears to be singularly deficient, for the district of Dr. Keily is not twenty miles in circumference, neither is it eight miles, and a considerable portion of that is open space.

You very offensively charge us with shabbiness; in reply, we offer Dr. Keily's own evidence in refutation of the accusation. The following letter was written by him to the committee last June, three months after their resolution respecting his cab hire had been sent to him.

2, Boon's-place, June 5th, 1885.

DEAR SIR,—Will you kindly communicate my best thanks to the committee for their great generosity in refunding the expenses incurred in procuring locum tenens. I am deeply sensible of the kindness of this spontaneous act on their part.—Very truly yours,

M. D. KEILY.

The amount referred to was £20. The rule respecting the settlement of disputes is a portion of the Friendly Societies Act bearing upon this point. Doctors may be fond of litigation, we are not, and consequently prefer to guard against it by availing ourselves of the means which the wisdom of our legislators have provided.

We are, Sir, yours obediently,

W. N. ELLIOTT, Chairman.
W. H. HOOPER, Vice-chairman.
W. COURTES, Secretary.

Stoke, Devonport, February 3rd, 1886.

*** We insert the above letter without being convinced by it of the injustice of our principal criticisms on the action of the authorities of the Three Towns Friendly Societies Medical Institution. The letter, indeed, contains evidence of the contrary, and shows that when the two medical doctors thought two fresh officers necessary, one only was appointed. As to the amount of cab fare *necessary*, we prefer the medical estimate of that to the estimate of the committee. Generally, we regret to say, we adhere to our opinion that the committee are not generous in their views of the value of medical service, or wise in expecting that so much work can be done for so little money and by such few hands.—ED. L.

SYMPATHETIC IRRITATION OF THE PNEUMOGASTRIC.

To the Editor of THE LANCET.

SIR,—I should be glad if any of your readers would favour me with suggestions for the treatment of the following case.

M. D——, six weeks advanced in her seventh pregnancy, is suffering from sympathetic irritation of the pneumogastric nerve, causing complete prostration, impediment to breathing, and very great distress. In her first four pregnancies she had no unusual symptoms from beginning to end; in the fifth the nerve irritation took the place of the usual morning sickness, and lasted till quickening, notwithstanding treatment at the hands of Dr. Priestley and myself. In the sixth the same train of symptoms occurred till a miscarriage resulted at four months. Now the same troubles exist. I have tried bromides and nerve-tonics of all kinds. My patient lies on a sofa, utterly wretched and depressed. I can find no mention of such cases in any text-book, and when I say that Drs. Priestley, Matthews Duncan, and Playfair have all seen and prescribed for the case without result, my anxiety will be understood. If any professional friend can offer any aid, I shall be very sincerely obliged. I am, Sir, yours faithfully,

Russell-road, Kensington, W., Feb. 4th, 1886. W. TOWERS-SMITH.

A Somerset Surgeon.—Scurf in the head is constituted either by epithelial desquamation occurring in slight or chronic inflammatory diseases—such as eczema or psoriasis, or ringworm—or by an abnormal outpouring and accumulation of sebum, just as scaliness of the general surface may accompany a number of conditions. The treatment will depend on the nature of the affection; but if the scurf alluded to is that characterising the common alopecia furfuracea, our correspondent will probably find effective the slight stimulation and cleansing of the scalp by tar soap, followed by the gentle inunction of weak citrine ointment.

"POISON FOR TWOPENCE."

To the Editor of THE LANCET.

SIR,—May I mention, in corroboration of your remarks (THE LANCET, Jan. 2nd, p. 30) upon a statement made by my predecessor at the inquest on a recent case of oxalic acid poisoning, that another case of poisoning by the same drug was admitted into the hospital last week. In this instance the patient had bought at a neighbouring chemist's the orthodox twopennyworth, of which quantity half had been taken. Fortunately, the symptoms were not of a very serious nature, and the patient soon recovered.—I am, Sir, yours faithfully,

WALTER G. AXFORD.

Jan. 26th, 1886. House Surgeon, Westminster Hospital.

Dr. Weaver.—Negotiations are now, we learn, in progress with respect to the matter.

Dr. H. Blanc (Cannes).—The paper will appear in an early number.

COMMISSIONERS IN LUNACY.

To the Editor of THE LANCET.

SIR,—Adverting to the leading article in your impression of the 6th inst. upon the subject of Lunacy Law Reform, you state that the Commissioners in Lunacy require a plateau of twenty-five acres upon which buildings having a frontage of 600 feet may be erected. Be good enough to inform your readers that the frontage alluded to would extend 600 *yards*. I am, Sir, your obedient servant,

London, Feb. 8th, 1886. G.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Edis; Dr. Braxton Hicks, London; Mr. Lawson Tait, Birmingham; Mr. L. Humphry, Cambridge; Dr. H. V. THE

Erasmus Wilson Lectures

ON

EVOLUTION IN PATHOLOGY.

Delivered at the Royal College of Surgeons.

BY J. BLAND SUTTON, F.R.C.S.,

ASSISTANT-SURGEON TO THE MIDDLESEX HOSPITAL, AND LECTURER ON COMPARATIVE ANATOMY.

LECTURE II.

THE INFLAMMATORY PROCESS.

MR. PRESIDENT AND GENTLEMEN,—Inflammation, when viewed in the broadest possible light, may be defined as *the method by which an organism attempts to render inert noxious elements introduced from without or arising within it.* Noxious elements capable of bringing about the phenomena peculiar to inflammation may be denominated *irritants.* Some of them are very coarse, others are peculiarly subtle, often eluding detection. The objective signs of the inflammatory process are so well known that it is needless to repeat them. The redness and swelling, as Galen knew, are the result of increased afflux of blood and exudation of serum, but the determining cause of the afflux has taxed the ingenuity of pathologists. It remained for the ingenuity of Cohnheim to devise experiments whereby the process could be objectively studied under the microscope. From direct observation carried out on the tongue and web of the foot of a frog, the tail of a tadpole, fins of fish, and mesentery of a mammal, we have been informed of the large part played in the inflammatory process by the white corpuscles of the blood. These experiments teach us that in vertebrata the most important feature in the inflammatory process is the vascular disturbance. The next question which suggests itself is this: What are the causes which originate all this vascular disturbance? For the present let it be simply said it is the result of irritation. If we extend our observations to other animals, especially the invertebrata, in whom many of the phenomena of cell life may be studied with tolerable ease, we shall quickly become impressed with the important functions played by active motile cells.

So far as inflammation is concerned, there are three points to which it is necessary to draw attention. They are: 1. The capacity exhibited by certain cells of effecting a change of place and form. 2. Their power of taking into their interior various substances with which they may come into contact. 3. The property they possess of decomposing organic material when in their interior or in contact with their protoplasm; this is termed intra-cellular digestion.

The first of these, or the inherent property possessed in many instances by protoplasm of moving with a rapidity perceptible with the aid of a microscope, is an acknowledged fact in biology. These movements may be produced by stimuli. The discovery by Wharton Jones in 1846, that the leucocytes of human blood possessed this property was a most important step. The capacity of the leucocytes to change their position forms one of the commonest of demonstrations in the physiological laboratory.

We must now consider the second statement—that of the power of ingestion. In 1862 Haeckel showed that when a tethys, a naked (shell-less) mollusk, is injected with indigo, the granules are taken up by the blood-corpuscles, and he further showed the occurrence of similar phenomena in the blood of various invertebrata. One of the most important results of these observations was the discovery that the cells of the blood of man and other vertebrates possess similar properties, and Cohnheim turned it to advantage in that it enabled him to demonstrate beyond question, that the migratory cells seen in the cornea when inflamed are directly derived from the blood.

Having considered the peculiar property of cells, whereby they ingest foreign bodies, it becomes essential to inquire concerning the fate of the ingested material, for it is of the highest interest in connexion with the process of inflammation. It has long been known that when an amœba takes into its interior a green-coloured plant, and is kept under observation, it is found that the ingested material gradually breaks up, loses its green colour, and finally disappears. The amœba is thus capable of taking food into its interior, and of making it part of itself, a process conveniently called nutrition, and is really the outcome of the process of digestion. When the process is carried on in a cell of this kind it is spoken of as intra-cellular digestion. Our knowledge of this process has been very largely extended by the researches of the eminent Russian biologist, Metschnikoff, who has done more than any other observer in this important and interesting line of inquiry. His investigations were first carried out on the sponges; later, he extended them to the hydroid polyps and hydro-medusæ. By using carmine he was able to watch its inception by the endoderm cells. In one case, that of Mesostomum ehrenbergii, the turbellarian refused to take the carmine; but Metschnikoff fed a nais with carmine, and induced mesostomum to eat the nais; examination showed the presence of carmine in the digestive cells of the turbellarian.

In 1880 Jeffrey Parker communicated to the Royal Society a paper on the Histology of Hydra fusca, which contains valuable evidence in support of intra-cellular digestion, and the paper is especially interesting in that it shows that the activity of the cells of the endoderm have not been sufficiently insisted upon, for in some cases by means of their pseudopodia the endoderm cells can actually obliterate the digestive case. He also shows that the endodermic cells carry on the process of digestion, for he found in their interior the partially disintegrated bodies of entomostraca. Soon afterwards Lankester was able to show that in the case of the fresh-water medusæ, which were discovered in the lily-house of the Botanical Gardens in 1880, intra-cellular digestion could be observed in these transparent forms. Interesting as these observations are, and valuable in that they prove the existence of intra-cellular digestion, yet it is necessary to detail the experiments by which Metschnikoff showed unquestionably that the wandering cells are capable of digesting organic substances. Human blood-corpuscles taken up by the mesoderm cells of bipinnaria become completely absorbed. Milk-globules share the same fate, and when taken up by the wandering cells, break up into small granules and diffuse themselves throughout the cell substance. The following experiment was devised to show that the cells do not ingest everything indiscriminately. On injecting into phyllirhöe living ova of a sea-urchin, it was found that neither young ovarian cells nor ripe ova which had extruded polar globules were eaten by the mesoderm cells; on the contrary, they seemed to live much longer than when placed in sea-water. Whilst in the tissues of phyllirhöe they could be fertilised, segmentation and a normal blastopore being produced. When spermatozoa of the sea-urchin were introduced they were quickly surrounded and eaten by the mesoderm cells. Observations on the necrotic organs of several invertebrates have shown that it is the function of mesoderm cells to devour the dying elements of such organs. If fluids containing bacteria be injected beneath the skin of bipinnaria and others, or if they develop spontaneously in the wounds of such animals, they will soon be found within the substance of many amœboid cells. In many cases the bacteria lose their motility and become so delicate as scarcely to be visible. In botryllus, Metschnikoff has found a spirochœte closely resembling the S. obermeyeri of relapsing fever and a small bacillus like the lepra bacillus. In both cases they were pursued, ingested, and absorbed by the mesoderm cells, some of which perished in the attempt and could be seen with long bacterial filaments projecting from them. The same process may be seen in the blood of vertebrates, where in bacterial affections such as anthrax the bacilli are taken up by the leucocytes.

We must now consider some examples of intra-cellular digestion in other than invertebrates. It has already been mentioned that this property of digestion possessed by cells is not merely used for nutritive purposes, but is also utilised for removing larval organs, and to protect the organism from harmful bodies. Before entering into details, it is necessary to refer to one other curious phenomenon presented by amœboid cells—namely, that of two or more cells fusing together so as to form a larger mass of protoplasm. Protoplasmic masses formed in this way are termed plasmodia. Metschnikoff has watched their formation, and regards them as equivalent to giant cells. In all cases in invertebrates they have arisen around foreign bodies, and

Digitized by Google

always by fusion of separate cells. There is abundant good reason to believe that giant cells in the higher vertebrata, when they do occur, arise from the fusion of leucocytes. In 1870 Dr. Caton published in the *Journal of Anatomy and Physiology* a contribution to the theory of cell-migration, and, as he points out, this process may be said to have its probable maximum activity in the tadpole. He further tells us that in the month of April he observed the process to take place to such an extent that he had some doubts that it might not be a possible physiological occurrence. The following observations have an interesting bearing on this point. Metschnikoff has shown that in the early stages of absorption of the tails of larval batrachians a large number of amœboid cells are present, within which are seen remnants of nerve fibres and fragments of muscle. These fragments of the tail are digested and absorbed by the amœboid cells, which are in reality leucocytes engaged in devouring the tail of the tadpole, and have been named in consequence "phagocytes." I have been able to follow the process in considerable detail by means of sections carried through the tail of tadpoles in various stages, and can fully confirm the observations of Metschnikoff with regard to the devouring propensities of the leucocytes. There can be little doubt that not only the tail, but also the gills, are eaten up in this manner. Bacteria are evidently an old source of trouble in the world; they affect animals of all kinds, even water fleas. Metschnikoff tells us of combats he has witnessed in the daphnia, between the white cells of the blood and bacteria, and how when one cell was not sufficient to attack the invading bacterium, two or more would fuse together, surround, digest, and thus rid the daphnia of the intruder. Can these facts be applied to mammals? If the cornea of a rabbit be irritated by nitrate of silver or a fine silk suture, the tissue becomes in a few hours red and hazy, due to escape of leucocytes from the vessels to repel, or if possible to destroy, the offending material. Draw a fine thread across the interior of a vein, leucocytes soon swarm around it. In tubercle, leprosy, perlsucht, or avian tuberculosis, the characteristic lesions swarm with bacilli. These minute organisms are often taken up by cells, and especially by giant cells, which in the two last mentioned affections crowd the affected area in great numbers. The consideration of these facts seems to indicate that in the giant cell we have the counterpart of the fusion of phagocytes, as in the case of the daphnia and other invertebrates, and it is in reality an effort of the blood-corpuscles to rid the tissues of noxious elements. The large multinuclear cells, osteoclasts, seen in bone undergoing absorption, must also be placed in the same category. These observations present the whole process of inflammation in an entirely new aspect, and instead of being a purely pathological process, it will rank as one of normal physiology, which when in excess comes within the domain of pathology.

At the commencement of the lecture it was stated that bodies capable of originating the inflammatory process were recognised under the convenient term of "irritants." Inflammation may be of two kinds according to the nature of the irritant. It may be simple or specific. Simple inflammation is the reaction which follows mechanical, thermal, or chemical stimuli or irritation. A specific inflammation is one which results from the introduction into the organism of a particular poison or irritant, such as variola, glanders, tuberculosis, perlsucht, actinomycosis, and the like. That the effects of inflammation vary with the irritant no one can deny. Dirt on a child's hand produces warts, decaying animal matter will in some cases produce veruca necrogenica; soot, the soot-warts, &c. No class of pathological productions illustrate the reaction of the organism to a specific virus so well as the peculiar group now known as the infective granulomata, which comprises tuberculosis, human, bovine, or avian; leprosy, syphilis, glanders, actinomycosis, &c. The histological characters of the morbid formations in each of these diseases are practically identical; a soft tissue made up almost entirely of round cells, very little intercellular substance, the presence of giant cells, and in most of them a bacillus or a fungus, is a constant feature. This infectiveness is very pronounced, for they may be transferred easily from one organism to another, and the "irritant" may be cultivated in artificial media. My observations, which have extended over the most important groups of the vertebrata, go to show that the mode by which a piece of noxious tissue is encapsuled or cast out of the body, is only an illustration on a large scale of the process by which bacilli, bacteria, micrococci, &c., are in some cases rendered inert by the activity of cells. If, as in the case of the daphnia, the quantity of micro-organisms invading the body is large, and the vitality of the organism enfeebled, the leucocytes are insufficient to cope with the invasion, and disastrous effects result.

If we summarise the story of inflammation as we read it zoologically, it should be likened to a battle. The leucocytes are the defending army; the roads and lines of communication, the bloodvessels. Every composite organism maintains a certain proportion of leucocytes as representing its standing army. When the body is invaded by bacilli, bacteria, or micrococci, chemical or other irritants, information of the aggression is telegraphed by means of the vaso-motor nerves, and leucocytes rush to the attack; reinforcements and recruits are quickly formed to increase the standing army, sometimes twenty, thirty, or more times the normal standard. In the conflict cells die and often are eaten up by their companions; frequently the slaughter is so great that the tissues become burdened by the dead bodies of the soldiers in the form of pus, the activity of the cell being testified by the fact that its protoplasm often contains bacilli &c. in various stages of destruction. These dead cells, like the corpses of soldiers who fall in battle, later become hurtful to the organism they in their life-time were anxious to protect from harm, for they serve as breeding-grounds wherein the bacteria may germinate, and, like a pestilence and scourge, devastate the individual. The analogy may seem to many a little romantic, but it appears to me to be warranted by the facts which I have ventured to place before my audience.

Clinical Lecture

ON

GASTROSTOMY IN THE TREATMENT OF ŒSOPHAGEAL CANCER.

Delivered at the Birmingham General Hospital, November 26th, 1885.

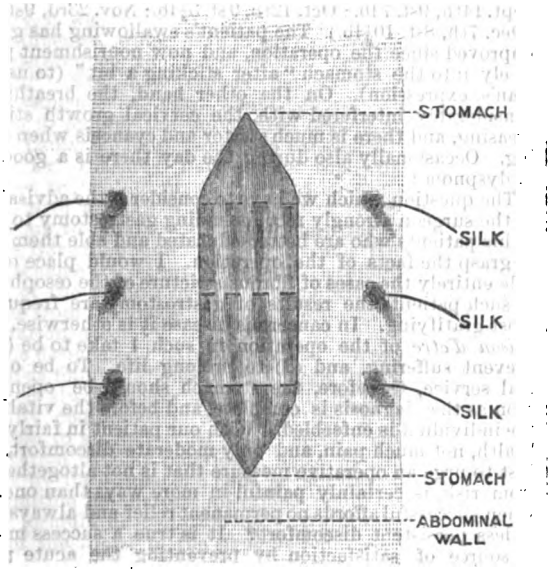
BY T. F. CHAVASSE, M.D., C.M., F.R.C.S. ED.,
SURGEON TO THE HOSPITAL.

GENTLEMEN,—The surgical treatment of cancerous stricture of the œsophagus has of late years received considerable attention. Three proceedings may be said to have proved of service:—I. The gentle passing of a small bougie through the stricture. II. The prolonged retention in the œsophagus of a tube passing beyond the stricture, in calibre equal to a No. 8 or 10 English catheter. III. Gastrostomy.

I. *The passing of a small bougie through the stricture.*—The effects of this proceeding are often most marked for a time, the patient being subsequently able to swallow liquids with comparative ease. The duration of this facility varies, but I have known it remain for several weeks.

A case that recently came under my notice was a private patient of Dr. Littlewood's, of Walsall. I saw him on July 22nd, 1885. The age was stated to be sixty-five; there was a history of gradually increasing, and at the time of consultation most pronounced dysphagia, of emaciation, and of syphilis acquired twenty years before. On examination an obstruction was encountered in the œsophagus, about five inches from the teeth. Eventually a tube the size of a No. 11 gum-elastic catheter was passed through this. The instrument was felt to pass over a roughened surface, and on its withdrawal was found streaked with blood. Immediately afterwards the act of swallowing was much improved, and up to the date of death (Sept. 29th) remained fairly satisfactory, especially if vinegar was taken to aid the downward course of nourishment.

I must, however, warn you not to repeat this procedure at frequent intervals when the diagnosis has been satisfactorily completed, or else a perforation of the walls of the gullet may thwart your efforts at alleviation.



II. *The prolonged retention of a tube in the œsophagus.*—Mr. Durham[1] states that in one case he kept the same tube in unremoved for four weeks, the patient feeding himself

[1] Holmes's System of Surgey, vol. i.

Digitized by Google

comfortably and satisfactorily through it. Except as a means of affording very temporary relief I am adverse to this plan of treatment—1. Because any structure the seat of a malignant neoplasm should be kept at rest, and not irritated in any way, if a slow development be wished for. A foreign body passing through an epitheliomatous growth in the œsophagus will certainly tend to increase the ulceration and the probable formation of a fistula connected with the trachea. At several post-mortem examinations of cases of malignant disease of the œsophagus I have noted the enlarged caseating and also suppurative condition of the glands round the upper opening of the stomach, and cannot but think that the pressure of a tube in the gullet for a long period would have a tendency to increase the glandular complication, perhaps more so than the mere passing of liquid food through the stricture. 2. Because in my experience the tube cannot always be tolerated, and when it is, it is very inconvenient and reduces the patient to a very helpless condition. 3. Because if an attempt is to be made to prolong life, gastrostomy will probably have to be resorted to at last, and then the operation is not performed under the most favourable conditions.

III. *Gastrostomy.*—Accepting the plan now universally adopted, of dividing the operation into two stages—that is, waiting for adhesion of the stomach to the abdominal

parietes before opening the viscus,—we will discuss the various methods now employed of obtaining firm adhesion.

1. *The simple suture.*—The stomach, having been exposed, is secured by four or more silk or wire sutures on each side to the edges of the abdominal incision. Mr. Bryant[2] thinks this is sufficient. In some instances it undoubtedly is. 'In a case sutured in this manner by my colleague, Mr. Jolly, a fatal termination occurring at the end of five days from pneumonia, the adhesions found at the post-mortem were enough for practical purposes. At the same time it must be borne in mind that the broader the surface offered for the approximation of the anterior stomach wall and the peritoneal lining of the abdominal wall, the better the chances of obtaining the desired adhesions. The simple suture does not offer a very broad area for adhesive formation, and if severe efforts at vomiting occur after the operation anxiety may arise as to its stability.

2. *A double row of sutures*, as introduced and advocated at one time by Mr. Howse. The outer ones, seven or eight in number, after passing through the anterior stomach wall, are made to pierce the parietes three-quarters of an inch from the margin of the abdominal incision, and secured externally by a piece of bougie or button. The inner ring, three sutures on each side, fasten the stomach wall to the edges of the skin. It must be evident that this plan offers a large surface of the stomach for adhesion, and great security if the organ must of necessity be incised for feeding purposes within twenty-four or forty-eight hours of the completion of the first step of the operation. As in the majority of cases this necessity ought not to present itself, and the application of the double row in actual practice will be found to be rather a tedious performance, Mr. Howse has recently advocated another plan.

3. This consists in clamping the anterior wall of the stomach with forceps sheathed in indiarubber, and which by their weight pull forward the viscus and keep it in position without the aid of stitches. The compression is not severe enough to cause sloughing of the stomach wall, and the forceps are left *in situ* for seven or eight days. This method has been successfully carried out by Mr. Howse.

4. This method may be called "the gather or running stitch." (See diagram.) It is very simple in its application, and in three cases in which I have employed it has proved effectual. It consists of three or four sutures passed transversely through the peritoneal and muscular walls of the stomach and out again three or four times, and piercing the abdominal parietes on each side about two inches beyond the edges of the incision. By tightening the sutures so introduced the edges of the primary incision are brought into apposition, and the anterior wall of the stomach pulled up and maintained in close contact with the parietes, leaving only about half an inch of the viscus exposed, to which the silver wire suture, introduced longitudinally at an early date of the operation and left protruding, is a guide for the subsequent puncture.

5. *Mr. Boyce Barrow's method.*[3]—The stomach having been exposed, a portion of its anterior wall is pinched up by the fingers of the operator. Two good-sized hare-lip pins are made to transfix it, seemingly through its whole thickness, in a direction transverse to the skin wound and about half an inch apart. The projecting ends of the pins are carefully protected by indiarubber. Catgut sutures are then used to bring the deep peritoneal and superficial parts of the wound closely round the pins and protruded portion of the stomach. No sutures are introduced into the viscus itself. The operation in the case in which it was first performed was completed on the tenth day, and the patient lived for three months afterwards. The advantages claimed for this plan are that it is very simple and quickly performed, and the stomach, it is thought, may be opened early if needed, without fear of extravasation. The only objection I can imagine is that the passing of the pins may result in the formation of additional gastric fistulæ, as they must be of a good size and allowed to remain until after the completion of the second part of the operation.

We will now proceed to the details of some cases in which the operation has been undertaken.

Hugo R——, aged fifty-six, labourer, was admitted into the General Hospital on March 14th, 1884. Ten months previously he noticed that the throat felt sore, that swallowing was accomplished with some little difficulty, and that solid food regurgitated. This was followed by an interval in which liquids could be swallowed pretty easily, and then again difficulty occurred. The exact position of the obstruction seemed opposite the top of the sternum. On March 11th the patient's neck began to swell on both sides, and as this was accompanied by complete inability to swallow nourishment he became an inmate of the hospital. On admission the man was emaciated, and efforts at swallowing caused much pain in the throat. No glandular enlargement to be felt in the neck. The passage of an œsophageal bougie was obstructed at a point opposite the top of the sternum, but a No. 11 tube was passed into the stomach. The relief caused by this step was most marked. Swallowing now became comparatively easy, so much so that the patient declined any further operative interference; he therefore left the hospital on March 19th. In June he was again admitted, the obstruction being complete and the wasting more apparent. On the 14th laparotomy was performed by means of a longitudinal incision parallel to the edge of the left rectus muscle. The stomach was secured to the abdominal wall by means of three running sutures. The patient never complained of much pain, and his highest evening temperature was 101°, that in the morning never falling below normal; still there was slight distension of the abdomen, and a more or less persistent pulse of 100, with a thready tendency. Pulmonary irritation was marked from the time of the recovery from the ether. Nourishment was administered by means of pancreatised enemata, not always well borne, and on the

[3] Paper read before the Medical Society of London, session 1884-5.

Digitized by Google

second day in very small quantities by the mouth. All the stitches were removed by the fifth day, and on June 20th the stomach was incised and a tube introduced for feeding purposes. Three days later the outer portion of the lowest stitch-hole sloughed, and a fistulous opening, the size of a large pin's head, communicated with the stomach. This was the result of the suture having been passed too deeply and penetrating the mucous coat. The man died exhausted on July 1st.

Pathologist's report.—Body much wasted; hardly any subcutaneous fat. Heart healthy. Lungs: Old pleuritic adhesions on the left side; hypostatic pneumonia of the right base. Liver congested; universal peri-hepatitis. Kidneys: Right normal; left intensely congested. Intestines: There was found some matting together of the intestinal coils by flakey lymph, especially in the left iliac region where there was reddening, but no ulceration; about half a pint of semi-purulent fluid was present in the peritoneal cavity. Stomach: This was adherent firmly to the abdominal wall, over an area of some two inches in diameter. The organ had been incised close to the pylorus, and had very thin walls, the mucous membrane looking as though considerable atrophy had taken place. The whole cavity appeared somewhat dilated, and at the cardiac end presented much capillary ecchymosis. Œsophagus: Has a large deep ulcer four inches long, reaching to within one inch of the cardiac end of the stomach, and on the average involving three-quarters of the circumference of the tube, except at the upper end, where a small strand one-eighth of an inch wide was all that remained of the mucous membrane. The edges were deeply undermined, especially the upper and lower ones. There were no granulations visible, the ulcer having an entirely necrotic appearance. The wall of the tube was injected and thickened. The lumen was smallest at the upper limit. The neighbouring lymphatic glands were mostly pea-sized, tough, but not caseous or indurated.

The causes of death after gastrostomy may be said to be—(1) shock, (2) peritonitis and exhaustion, and (3) bronchopneumonia. In the last two and a half years gastrostomy has been attempted six times for carcinoma of the œsophagus at the General Hospital; of these, three cases fell to my lot.

First Case.—Man, aged fifty-eight. First stage of operation, May 15th, 1883; stomach secured by a single row of sutures. Died in five days. Stomach unopened. Cause of death, exhaustion, lobar pneumonia.

Second Case.—Man, aged forty-five. First stage of operation, May 29th, 1883; stomach secured by a double row of sutures; incised eleven days later. Died ten weeks after first operation. Cause of death, exhaustion. A large cavity containing nearly a pint of pus was found lying between the lobe of the liver and the stomach wall.

Third Case.—Man, aged fifty-two. First stage of operation, Oct. 30th, 1883; stomach secured by gather stitches; incised ninth day. Died Nov. 26th, 1883. Cause of death, lobar pneumonia. (Weight of patient two days before death, 5 st. 8½ lb.

Fourth Case.—Man, aged fifty-six. First stage of operation, June 14th, 1884; stomach secured by gather stitches; incised fifth day. Died July 1st, 1884. Cause of death, subacute peritonitis, pneumonia, exhaustion.

Fifth Case.—Man, aged fifty-two; operation completed Aug. 30th, 1884; stomach secured by a single row of silver sutures; died Aug. 31st; cause of death probably shock; lobar pneumonia of right base.

In four of these five fatal cases pneumonia was found at the post-mortem examination. Abscess in one, probably due to perihepatitis; subacute peritonitis in one also. In the case where it was found necessary to complete the operation at one sitting in a worn-out patient, the shock necessarily attending the procedure was not recovered from.

The sixth case is now before you, the details of which are as follows:—

Thomas M——, aged fifty-six, a cab-driver, was admitted into the General Hospital on July 18th, 1885. Four months before admission he first felt something sticking in his throat, this being accompanied by a difficulty in swallowing solid food. A few weeks afterwards he perceived a small kernel, the size of a marble, on the left side of the neck, just below the angle of the jaw. This growth increased in size, and immediately before admission the voice became husky and the breathing embarrassed on the slightest exertion. No food of a solid nature had been taken into the stomach for a week, and but very little milk. The patient had steadily lost flesh from the date of his earliest symptoms. The family history tells that one brother died of cancer of the breast, and within the last fortnight his sister from uterine carcinoma. On admission the man was emaciated, had a husky voice, and dyspnœa on exertion. On the left side of the neck a hard infiltrating glandular mass presented. A moderate-sized bougie introduced into the œsophagus was stopped six inches from the teeth, and on withdrawal bore traces of blood and granulation tissue. The pupil of the left eye was contracted to the size of a pin's head, owing to the pressure upon the cervical sympathetic nerve. On July 23th the first stage of gastrostomy was performed. Three gather stitches were introduced. Pancreatised enemata was ordered every third hour. On the 29th ice was sucked to relieve the great thirst. Had slept nearly eight hours the first night, and felt very little pain. The highest temperature recorded took place on the second evening—viz., 101·4°. On the 30th two ounces of milk and soda-water, besides ice, were administered by the mouth. The gather sutures were removed on July 31st, August 1st and 3rd respectively. On August 5th the stomach was opened and food introduced through the fistula. On the 9th the patient sat up. The nourishment taken during twenty-four hours was forty ounces of milk, ten ounces of beef-tea, two ounces of port wine, the meat (minced) from a chicken's breast, and three eggs. Weight: August 30th, 8st. 12lb. (had gained 8lb.); Sept. 14th, 9st. 7 lb.; Oct. 12th, 9 st. 3½ lb.; Nov. 23rd, 9st. ½ lb.; (Dec. 7th, 8st. 10½ lb.) The patient's swallowing has greatly improved since the operation, and now nourishment passes freely into the stomach "after sticking a bit" (to use the man's expression). On the other hand, the breathing is considerably interfered with, the cervical growth still increasing, and there is much stertor and cyanosis when sleeping. Occasionally also during the day there is a good deal of dyspnœa.[4]

The question which we have to consider is the advisability of the surgeon strongly recommending gastrostomy to those of his patients who are better educated and able themselves to grasp the facts of the operation. I would place on one side entirely the cases of fibrous stricture of the œsophagus; in such patients the results of gastrostomy are frequently most gratifying. In cancerous disease it is otherwise. The *raison d'être* of the operation in such I take to be (1) to prevent suffering, and (2) to prolong life. To be of any real service, therefore, the stomach should be opened as soon as the diagnosis is complete, and before the vitality of the individual is enfeebled. With our patient in fairly good health, not much pain, and only moderate discomfort, is it just to urge an operative measure that is not altogether free from risk, is certainly painful in more ways than one, and when successful affords no permanent relief and always more or less persistent discomfort? It is true a success may be a source of satisfaction by preventing the acute pangs of starvation becoming dominant, and the painful results consequent upon the formation of a fistula between the œsophagus and trachea. The prolongation of life itself is, after all, only a matter of a few months, and is such an existence desirable? Possibly it is a matter that an intelligent patient ought to decide for himself, after the ungarnished facts have all been placed before him by the surgeon. He may, if supplied with the luxuries of life, elect to bear, aided by the palliatives of the milder forms of treatment, until the unbearable be reached, and then seek relief by other means than those afforded by surgery. With those in the humbler walks of life it is perhaps better to operate early, and to maintain, and from time to time to utilise, the gastric fistula, retaining the cases under one's personal supervision. It appears more humane to adopt this course rather than expose them to the uncertainties of their own rude fare, the surroundings of their questionably comfortable home, and the want of constant and adequate nursing and professional care.

[4] The man died in hospital on Jan. 23rd, 1886, with double pneumonia. For the three preceding weeks nourishment could only be taken through the fistula. He repeatedly expressed himself "tired of life."

HOSPITAL ACCOMMODATION FOR MERTHYR TYDVIL.—Although the population of this union exceeds 100,000, there is at present no public hospital at Merthyr Tydvil. The Marquis of Bute has intimated his willingness to subscribe £1000 towards the erection of a suitable building to be devoted to such a purpose, provided that at least a sum of £2000 is subscribed by others interested in the parish.

THE DARWINIAN "WORKING HYPOTHESIS OF EVOLUTION" EXAMINED PHYSIOLOGICALLY.

By T. WHARTON JONES, F.R.C.S., F.R.S.

ACCORDING to the Epicurian doctrine recited by Lucretius in his poem "De Rerum Naturâ," "it was not by design that atoms framed the world; but after many fruitless collisions they chanced to fall into such motions as produced the world and all that is in it. At first monsters of all kinds were formed, which could not grow up nor continue their kind. They all therefore perished off." "The members and organs of the body," further said Lucretius, "were not formed by design, but having been formed, came to be applied to the uses for which they were found adapted." Whilst Epicurus thus taught that organised structure determined function, M. Lamarck, in his "Philosophie Zoologique," published in France about eighty years ago, formulated a scheme of evolution, according to which "it was not the form of the body or of its parts which gave rise to the habits and mode of life of animals, but, on the contrary, it was the habits and mode of life, together with other influences, which have in the course of time—ages and ages—determined the form of the body and parts of animals." Nay, new organs having become necessary in consequence of new wants, efforts were made by animals to acquire the desiderated organs, and so, according to Lamarck, they came into existence! In a similar strain, Dr. Erasmus Darwin, in this country, argued that the acquisition of new organs in the course of the evolution of animals was the result of their own *nisus* or endeavour to obtain what they longed for! The late Mr. Charles Darwin, grandson of Dr. Erasmus Darwin, objected to the scheme traced out by Lamarck, as affording no explanation of the process by which organised bodies have been evolved from the lowest to the highest. The efficient cause in operation, according to Mr. Darwin's own view, has been what he designated "natural selection"—a process described by him as follows: "Amid the struggle for existence which has been always going on among living beings, variations of bodily conformation and structure, if in any degree profitable to an individual of any species, *will* tend to the preservation of that individual, and *will* generally be inherited by its offspring. Thus is 'survival of the fittest' the condition for 'natural selection.'"

This formula of evolution by "natural selection, by survival of the fittest in the struggle for existence," seems, in reality, no more than what Epicurus taught in Athens, and after him Lucretius sang in Rome, and is no explanation, but merely a form of words without any basis in fact. I have, however, seen it somewhere actually stated that Mr. Darwin *discovered* natural selection—an amusing example of confusion of ideas respecting the difference between *discovery* and *invention*. The fundamentally similar construction of the human arm and hand, for example, the forelegs and feet of quadrupeds, wings of bats, flappers of seals, paddles of whales, and wings of birds, is, argued Mr. Darwin, inexplicable on any other supposition than common descent. All this, again, it must be affirmed, is a mere conceit, a conclusion without premisses. Such similarity of plan in the construction of their organs does not logically prove that the different races of animals have been evolved, the highest from the lowest, in the manner alleged. The process of change in the course of ontogenesis or the development of the embryo from the ovum to the state of the grown animal comprises a *differentiation* of structure; but, let it be particularly remembered, this *differentiation* is a *real* and *observable* development, and must not be confounded with the *imaginary* differentiation by transmutation, arbitrarily assumed by evolutionists to be the process of change in what they call *phylogenesis* or evolution of the line. Any variation in the development of an embryo, whether by excess or defect of the normal structure which may take place, is merely a monstrosity. In main features, the early human embryo does not, at first glance, seem to differ much from the correspondingly early embryo of a dog, for example; but notwithstanding this, they differ potentially from each other. By virtue of internal qualities and hidden power, the two somewhat similar aggregations of cells are at last unerringly developed—the one into a man and the other into a dog.

That races of living beings have had their form and structure, and consequently their functional endowments, transmuted by *natural selection* or any other imaginary process of evolution in a long course of ages, and that they have thereby become different from the organisms whence they sprang, are propositions not supported by any legitimate induction from facts. In the metamorphoses of the frog we can observe how the limbs and lungs make their appearance, and how the tail and gills of the tadpole disappear, so that the animal from being virtually a fish comes to be an air-breathing batrachian. These changes of structure and function constitute natural stages in the ontogenesis or process of development of the individual. The hind legs are first formed and assist the tadpole in swimming; but when the fore legs become, in due course, free, and the animal thereby fitted for progression on land, the tail, which was previously the organ of progression in the water, shrinks and disappears, while the gills for respiration in water are superseded by lungs for breathing air. In consequence of the diversion of the circulation of the blood from the tail, it becomes atrophied and reduced to a crust, which eventually falls off; the tail is not detached bodily, as commonly alleged. In a similar manner, the gills disappear by becoming atrophic in consequence of the diversion of the circulation of the blood from them to the swimming bladder now becoming lungs. All this process of metamorphosis, let it be repeated, constitutes an invariable stage in the ontogenesis or natural course of development to the frog state, and is no exhibition of a differentiation by transmution, such as is assumed to take place in what is called phylogenesis or evolution of the line. The transitional resemblances of form, the homologies and analogies of structure observable in the different races of organised beings, cannot, then, be admitted as indicative of any such thing as a proof of progressive evolution whereby plants or animals have by chance, or spontaneously, or by natural selection, whichever you choose to call the conceit, been transmuted from a lower to a higher grade of organisation with corresponding elevation of endowments. Though there is a resemblance among organic forms so far as to indicate a unity in the plan of the whole, a line of demarcation circumscribes, and has circumscribed so far as our cognisance truly extends, each kind or form.

An exposition of the affinities, the homologies and adaptations of structure throughout the organic kingdoms, is a great aim of philosophical anatomy; and the subject has been long ago pretty successfully worked out, even to the discovery of new facts and to the tracing of the transition between invertebrates and vertebrates (a transition, however, not through an ascidian mollusk, as Mr. Darwin fantastically thought he had discovered); but how well made out soever the affinities, homologies, and adaptations of structure may be, and how valuable a key soever to the discovery of new facts the knowledge thereof has proved, their demonstration does not and cannot, from the very nature of the question, help to confirm scientifically the doctrine of evolution; it is a mere sophism to argue otherwise. The question is one beyond the pale of science, and any addition of facts of the kind appealed to will still fail to fill up the proof.

A word about nucleated cells. The nucleated cell is a microscopical corpuscle of albuminous nature in respect to substance, and in respect to structure comprises two distinct parts—viz., protoplasm and nucleus. These two parts are usually enclosed within a membraneous wall—a third element of structure; but this cell-wall, though it has given name to the whole corpuscle, is found not to be a constant or essential part of its structure. A lower phase of living, or at least *viable*, existence than the nucleated cell is found in the *cytode*—a shapeless mass of protoplasm without a nucleus, and which is assumed by evolutionists to have originated by spontaneous generation. Though originally homogeneous in composition, structure, and endowments, cytodes, nucleated cells, and tissues developed from them, have come at last, according to evolutionists, to form, by a process of differentiation, the various kinds of *corpora viva*. In contradiction of this, however, it is important to remember a fundamental principle in the biology of cells, a fundamental principle overlooked or ignored by evolutionists—viz., that cells are of various kinds, each kind possessing its own peculiar vital endowments and its own mode of further development. One kind of cells does not

Digitized by Google

give origin to another kind of different endowments. There is no such thing known as *differentiation* in the sense in which evolutionists have come to employ the term—viz., transmutation of endowments as well as of substance and structure—comparable to the transmutation of baser metals into gold, as pretended by the alchemists. Here I may repeat the remark made in my article on the Ova of Man and the Mammifera, that "differentiation" is a word which was imported by Professor von Baer into the vocabulary of development, but which has since come to be illogically usurped by evolutionists, as if, instead of merely indicating steps observable in the development which goes on before our eyes, it represented a *real fact* in proof of the evolution of organised and living beings from the lowest to the highest in all their various species, genera, and classes throughout millions of years—a phylogenesis which they fancy and gratuitously assume to have taken place.

The truth is, all that we know of cells is that they run through the different phases of growth and development proper to them, each kind according to its own fixed destiny. Granting any number of generations through which cells may be supposed to have descended, the evolution argument is not thereby strengthened or confirmed. When, by virtue of their own original intrinsic qualities, differently composed and endowed cells are, under the appropriate conditions, developed into tissues, each kind in its own proper way, the process is truly one of "differentiation" in the sense in which it was first employed in embryology by von Baer, but there is certainly no such process in nature, if by the expression is meant the development by transmutation of different kinds of tissues from one and the same kind of cells by their own desires and efforts with the resulting formation of new organs with correspondingly new endowments. The reality of such an imaginary process is, in fact, the very point to be contested, as the false foundation on which the superstructure of evolution has been in a great measure built.

Though resembling each other in their general characters, organic cells, let it be repeated, are of various kinds, each kind possessing its own peculiar endowments, physical and vital, and its own mode of further development into tissues and organs. One kind of cells cannot give origin to another kind with different endowments, nor be developed by the chance of circumstances into this or that kind of structure. Cells react vitally under varying conditions, but each kind only in its own way. If the conditions be unusual, the cell still reacts after its own manner, according to its inherent potentialities, so far as the unusual conditions permit. Cells may, indeed, become morbid, languish, and die under the influence of unfavourable conditions, but they never react in such a way as to be converted by transmutation of substance or evolutionary *differentiation* into some structure and organ of a fundamentally different nature from that which is normally the product of their development.

The elements in respect to shape composing the various tissues of the organs of a *corpus vivum* are formed out of the substance of cells, their nuclei, and intercellular substance; and though thus similar in the mechanism of their development, organs differ from each other, not only in shape and structure, but also in endowments, physical and vital—a necessary result from their component tissues being developed each from its own kind of cells. In short, the various cells, though they may resemble each other in external aspect and general points of structure, and the endowments thereon depending, are intrinsically different in their potential vital qualities. No transmutation, therefore, can, under any circumstances, take place of one kind of cell into the structure which is the proper product of the development of another kind of cell; nor can one kind of glandular cell elaborate the secretion which is produced from another kind. That the peculiarly endowed brain cells of man could ever have been evolved in the course of any number of generations throughout millions of years from the differently endowed brain cells of lower animals, is the merest fancy, as is, of course, also that any increased mental activity of an ape could have led to the evolution of the human mind.

Admitting that the nature of the physiological factors to which evolution is due is still open to discussion, and thus quietly giving up the form of words excogitated by Mr. Darwin to designate the efficient cause of evolution—viz., natural selection by survival of the fittest—evolutionists now fall back upon the palæontological facts disclosed by geology as decisive historical proof that evolution has actually taken place. For example, the one-toed horse of the present day was preceded on the earth by a three-toed horse, and it is assumed that the former has been evolved from the latter by the suppression of the phalanges of its rudimentary toes and other slight modifications. But supposing, for argument's sake, this descent of a one-toed from a three-toed horse, it would go a very little way in support of the doctrine of evolution by transmutation of structure and endowments, such as the evolution of the human brain from that of apes. Children are sometimes born with six toes, and reproductions of the malformation in the family are not uncommon; but herein we have no example of a new and improved edition of the breed. In regard to the three-toed fossil hipparion, we may indeed recognise in its bones and teeth characters indicating a near relationship to the horse tribe of the present day. We may also recognise, on the other hand, in the embryo of the said tribe indications of a three-toed development; but to say, for that reason, that a horse, a zebra, or an ass has been evolved from the prehistoric hipparion by natural selection, by survival of the fittest, is a logical inconsequence. All that palæontology teaches us is that various organic forms have in succession lived on the earth in the course of long periods of time, and that such forms, in like manner as the various forms of the present day actually do, exhibit in their fossil remains a close resemblance to each other in their transitional homologies. Herein it is obvious that we have no logically scientific proof that the organic forms, of which the fossil remains are first found in the strata of a later geological epoch, had been any one of them (e.g., the horse-tribe of the present day) evolved by transmutation of structure and endowments in fortuitous succession from a different form—e.g., the hipparion, of which the fossil remains are found in strata of an earlier geological period. This fallacious attempt to prove the validity of evolution by an appeal to palæontology is not to be confounded with the perfectly logical endeavour of Cuvier to construct from the study of fossil bones and teeth as data an anatomical and physiological history of the animals, of which the said bones and teeth are the actual remains. If, in the alleged evidence from palæontology, we had really a logical proof that evolution of organic forms in the manner contended for has actually taken place, it would then not be so difficult to understand the nature of the physiological factors in operation, even though the process may have been one requiring millions of years for its accomplishment. We should, however, have to admit that one kind of cells can give origin to other kinds which may be developed by the chance of circumstances into this or that kind of structure with this or that kind of endowments. The process in such a case would be similar to that in the development of the frog, as above described, but taking place fortuitously with the superaddition of differentiation by transmutation of structure and endowments.

In regard to the evolution of mind and language Mr. Darwin gave utterance to the speculation that the continued use of language has led to the evolution of the intellect, notwithstanding that it is self-evident language presupposes already existing intelligence as well as the proper organs of voice and speech. Then, again, it may be asked did the *nisus* to speak lead to the evolution of the organs of voice and speech, or did speech follow the fortuitous evolution of the organs? Leaving such *niaiseries* aside, let Professor Max Müller speak:—"The words in all languages," says he, "are built up from comparatively few roots, so that the whole question of the origin of language narrows itself into the problem of the origin of roots. All living things are built up of small cells, and evolutionists are anxious to picture cells uniform from the beginning. Roots of words are the cells of philological science, but the philologist sees no evidence that their number can be much reduced, or that they can possibly be traced to a single source. Roots are neither interjections nor imitations of the sounds of nature, and it is utterly impossible that they could have been formed till the animal began to generalise from observed facts and began to have the power of counting. The intellect and the language of man began at the same time, so there must have been a definite and distinct line at the outset separating man from the lower animals."

Postscript.—In the *Nineteenth Century* for November there is an eloquent article by Mr. Gladstone on the "Dawn of Creation and Worship," which has called forth a reply in the same magazine for December by Professor Huxley,

Digitized by Google

under the title of the "Interpreters of Genesis and the Interpreters of Nature," to which, in the January number, Mr. Gladstone has published a rejoinder under the title of "Prœm to Genesis—a Plea for a Fair Trial."

Mr. Gladstone's aim is to vindicate the inspired authority of Genesis against Dr. Réville's "Prolegomena to the History of Religions." Admitting that the Mosaic account of the sequence of creative acts is not quite borne out by the observed facts of geology and palæontology, but recognising the "days" as geological periods, he contends that the two accounts are in sufficiently substantial agreement. Though not formally impugning the Darwinian doctrine of evolution, he objects to it as not affording any solution of the great *arcanum of creation*, seeing that a merely corporeal evolution would not account for the origin of mind and spirit. Besides this, he protests against the doctrine on account of the atheism involved in it.

Mr. Huxley's reply, in correction of Genesis, and in opposition to Mr. Gladstone's views, comprises a scientific exposition of the observed facts of geology and palæontology relating to the succession in the appearance on the earth of the various kinds of plants and animals. This exposition, however, does not prove the validity of the Darwinian hypothesis of evolution, which, notwithstanding all that has been said for it, still remains unverified and unverifiable. See page 68 of my lectures, entitled "Evolution of the Human Race from Apes and of Apes from Lower Animals—a Doctrine unsanctioned by Science" (1876). From this volume I may here, in conclusion, quote the following passage: "It is commonly assumed by evolutionists, and tacitly granted them, that there are only two fundamental alternatives between which a definite decision has to be made—viz., revelation or evolution. But this I emphatically deny. Unbelief in revelation and a personal Creator is no doubt the alternative of the admission of evolution, but admission of evolution is not the necessary alternative of unbelief. Excluding all belief in revelation and a personal Creator, for argument's sake, I hold that the doctrine of evolution, unsanctioned, as I believe I show it to be, by science, cannot be accepted as the alternative on any consideration, and must therefore be unconditionally and absolutely rejected."

A NOTE ON ABDOMINAL SECTIONS.

By W. F. WADE, F.R.C.P.,

SENIOR PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM.

THE mention of my name in Mr. Lawson Tait's paper on Cholecystomy reminds me of a purpose which has been for some time in my mind. I wish to address a few words to those who, like myself, are exclusively, and to those who, as general practitioners, are chiefly, engaged in the treatment of medical as distinguished from surgical cases. Before us, acting in this capacity, cases come which no doubt are in their inception properly catalogued as medical, and which a few years ago would have remained so to their termination. Medicine might fail, but surgery had nothing to offer. That is not so now. The Birmingham school of gynæcological surgeons has increased the resources of civilisation, and their fellows elsewhere are, somewhat slowly and reluctantly perhaps, following in their footsteps. But the sick public will not have the full benefit of these new resources till we who practise medicine give our fiat and sanction to them. Ought we to do so? I am not a surgeon, and therefore am not swayed by a desire to operate whenever an operation is possible, as some suppose habile operators to be swayed. On the contrary, I feel always a certain amount of chagrin when compelled to say, "Medicine is powerless, but surgery is not." Yet I feel obliged to admit that in some cases, which, as already pointed out, have up to now been regarded as exclusively medical, our efforts ought to be supplemented or supplanted by those of the surgical operator. Another question now naturally arises: In what class of cases, and to what extent in that class? This is a question which I regard as still *sub judice*. Instead, then, of attempting to give a direct answer, for which the time has not yet come, I will very briefly narrate four cases which have happened to me in the ordinary course of private practice within the last six months, in which I suggested the advisability of abdominal section, and in which, in accordance with that advice, it was performed.

1. The patient mentioned by Mr. Tait. An elderly lady had for more than a year had at intervals symptoms of the passage of gall-stones, severe pain requiring morphia, and jaundice; perfect recovery in the intervals. For some weeks before I saw her the intervals had been so shortened that the jaundice of one attack had not time to disappear before the next occurred. Her appetite and strength were failing, so that her condition was becoming precarious. She was believed to have had about 100 attacks. I told her that she might have a hundred or two more stones to pass, and that before the bladder was emptied she might perish from exhaustion; that I considered she was in greater danger from this than she would be from an anæsthetic and the operation. The latter risks I therefore advised her to accept. I have never seen her since, but heard that she had decided to do so, and had placed herself under Mr. Tait for the operation, the result of which he has given in THE LANCET of the 13th inst.

2. A child six years of age was attacked with abdominal symptoms of a mild character, fairly supposed by the family attendant to be due to gastro-intestinal disorder. After three days he one morning became suddenly much worse. As I happened to be away all day on a country journey I did not see him till late at night. He was then in a condition which must pretty evidently be fatal, and which indicated the existence of peritonitis. I advised that the only chance left for him was to have his abdomen opened. This was done by Dr. Malins, and a good many ounces of most abominably fetid pus escaped. He was more comfortable after the operation, but died in about twenty-four hours, and I do not know that his death was either delayed or hastened by the operation. But I assume that a person is more likely to recover without than with a quantity of fetid pus in his abdominal cavity.

3. A boy of twelve was much reduced by peritonitis of three months' standing, and consequent hectic. On the right side of the abdomen, about the ileo-cæcal region, was evidently a collection of what we presumed to be pus. There was on the corresponding left side (where the inflammation had began) tenderness, but no evident collection. I advised the friends that it would probably be necessary to open the abdomen. But as they were anxious to avoid this if possible, we agreed to have a further trial of medicine, and gave him some syrup of the iodide of iron and some conium. He improved as to general condition, but after a second relapse, the local conditions remaining unaltered, I pressed them to consent to an operation, which they did, and Mr. Tait opened three loculi containing pus, one on the right side, one on the left, and one deeply seated towards the back. There was an immediate return to normal temperature, but there have been two recrudescences of fever, and the case, which it was all along feared might be of a tubercular character, is still in abeyance.

4. A female of about thirty, married, was said to be suffering from peritonitis. This was undoubtedly so, and her aspect, pulse, temperature, and vomiting showed that she was in a very serious condition. She referred her subjective symptoms to the upper part of the abdomen; they had existed severely for several days. But on further inquiry there was a previous history of pain for several days of a slighter character, and in the left ovarian region. Vaginal examination showed a good deal of fulness and extreme tenderness to the left of the uterus. I came to the conclusion that the original seat of disease was the left uterine appendages, and that there was very probably pyo-salpingitis. I advised that if the symptoms did not abate, and still more if they increased, the abdomen should be opened and this region explored. This was done about a fortnight after by Dr. Savage; the appendages were with difficulty removed; the ovary was enlarged and inflamed, and pus was found in the Fallopian tube. The patient did well.

These cases admit of, and indeed suggest, plenty of discussion, comment, and criticism. But into this I do not propose now to enter, my present object being only, as stated at the outset, to show that there are cases hitherto supposed to be purely medical, and as such met with in a purely medical practice, which do admit of, and in my opinion require, surgical interference. These cases were, it will be noticed, treated by gynæcological surgeons; but at least two of them any good general surgeon—one, for example, who would not hesitate to operate for strangulated hernia—ought to be quite prepared to undertake.

ON THE CAUSE OF HEPATIC ABSCESS.

BY H. BLANC, M.D., F.R.C.P.

SURGEON-GENERAL MOORE, in THE LANCET of Oct. 31st, 1885, correctly refutes the views held by Dr. Harley in his interesting work on Diseases of the Liver regarding the cause of hepatic abscess, which Dr. Harley too exclusively attributes to "gluttony and intemperance." I also concur with Surgeon-General Moore in his statement that natives of India are quite as liable to hepatic abscess as Europeans. On this point I am able to speak from personal knowledge, having, during my ten years' residence in the town of Bombay itself, held appointments in both the native and the European general hospitals. But whilst joining with Dr. Moore in repelling the general charge of "gluttony and intemperance" as the principal cause of hepatic abscess among Europeans residing in India, still it must be confessed that intemperance is frequently noted in the previous medical history of both natives and Europeans who suffer from hepatic abscess, and although overfeeding is much less common, yet we frequently find among these patients the habitual use of hot-spiced food as a diet.

Hepatic abscess is rarely met with in Bombay among the better class of European residents, and although I had many opportunities of seeing such cases, had they existed, I can scarcely remember, during a period of some ten years, more than half a dozen cases among this class of people. On the other hand, hepatic abscess is not unfrequently met with among the inmates of the European General Hospital. As physician in charge of that establishment, a certain number came under my care; and from my notes I find that during the last two years, or thereabout, I actually operated upon sixteen cases; moreover, during the same period, a certain number came also under the care of my able colleague, Dr. Manser. The table herewith appended shows that most of the cases therein recorded (the only ones I have by me) occurred among individuals who by their occupation were subjected to much exposure, and although some are entered as "temperate," their temperance was but relative; the work which many of them had to perform was a "thirsty one," and most of them considered a few bottles of beer and a few glasses of brandy daily, so long as they did not actually get drunk, as quite compatible with temperance.

I do not think that "a chill," as advanced by Surgeon-General Moore as the cause of hepatic abscess, is in reality a frequent cause of that disease—an occasional cause no doubt it is, but nothing more. The climatic condition insisted upon by him—i.e., daily great variations in temperature, is not special to India by any means. If hot days and cold nights were such a powerful cause of hepatic abscess, then that affection would not be limited, or nearly limited, to tropical lands; for instance, in the south of France, where I am now residing, at this season of the year the extremes of temperature between the hot sunny days and the cold, sometimes frosty, nights, are greater and more marked than in Bombay itself during the winter there, and yet hepatic abscess is totally unknown here! A great authority on tropical diseases, Sir Joseph Fayrer,[1] speaking of the causes of hepatic abscess, says: "They appear to be a result of climatic causes, to which some constitutions are more prone than others, and in certain instances aggravated, no doubt, by injudicious eating and drinking, though it may happen in those who have observed the greatest moderation." My own experience leads me to the same conclusion.

Among the climatic causes, those to which malarious fevers are due stand also foremost as the cause of hepatic abscess. We find usually in cases of hepatitis, whether ending in abscess or otherwise, a previous history of malarious fever, and it is quite exceptional to meet with individuals who have never suffered more or less recently from malarious fever, or who have not at least resided for a length of time in highly malarious localities. Among malarious fevers the remittent type is the one most frequently followed by hepatic abscess. During the prevalence of this fever the liver is always somewhat congested, at times very much so; and if the patient is one "more prone than others," congestion passes into inflammation, and in many instances an abscess follows. Among the eighteen cases of hepatic abscess here given, malarious fever existed previous to the appearance of the abscess in no less than fifteen cases. The three exceptions are: (*a*) a man who, according to his own statement, was very intemperate; (*b*) a man also very intemperate, and who had been exposed for days to the dreadful heat of the engine-room during the hottest month in the Red Sea; (*c*) a man who, though he stated that he was temperate, gave physical signs of alcoholism—i.e., a tremulous tongue, sleepless nights, &c.; moreover, he had passed a night exposed to the wind and rain.

Another point of interest in these cases is the season during which they occurred. In Bombay the so-called "cold weather" scarcely ever sets in before the middle of December, lasting only until the first days of March. If cold nights, alternating with hot days, is the cause of

hepatic abscess in India, we should expect to meet with a greater frequency of these abscesses between the middle of December and the beginning of March; but such is not the case. Even among the eighteen cases here recorded two only pertain to the cold season: all the others occurred between the months of June and November, a period characterised in Bombay by an equably high temperature and by the great prevalence of malarial fevers.

Cannes.

CATARACT EXTRACTION PERFORMED ON AN INSANE PATIENT.

BY T. H. BICKERTON, M.R.C.S.

THE following case of cataract extraction may be of some little interest from the fact that it occurred in the person of an insane individual. The patient in question is an inmate of the Rainhill County Asylum, and I have to thank Dr. Rogers, medical superintendent of that institution, for his permission to perform the operation, and also for his permission to mention the case. The history is as follows:—

John T——, aged seventy-one, was first admitted into the asylum in 1868 as a suicidal patient. Between 1868 and 1872 he was twice discharged, and being in the latter year readmitted for the third time, he has remained an inmate ever since. The first note that there is about his vision is in the asylum book for 1876, where the remark is made that he is "gradually losing sight from cataract." His own statement, however, on the matter was that the sight of the right eye had been lost for twenty years. The vision of the left eye gradually failed, and more than twelve months ago he became totally blind, and since then he had to be led about by another patient. The right cataract was of a China-white variety, and as the pupil acted well, and the vision was fair for light and shade, it was considered that there was every probability of a successful result being arrived at. The patient was anxious to be operated on. The eye (right) being made insensitive by two applications of ten drops each, of an 8 per cent. solution of cocaine, the incision was carried as nearly approaching a Graefe's as possible, the wound being entirely in the sclerotic. On making the iridectomy, the lens was seen to be bulging greatly towards the wound; and on dividing the capsule, a sudden gush of fluid showed the cataract to be a fluid one, and carried up with the rush to behind the posterior lip of the wound was a small, hard-looking, red nucleus. Lying now in the pupillary space was the white capsule, and this after one or two attempts was removed entire by means of a pair of iris forceps, its slight adhesion to the posterior surface of the nucleus giving way to gentle side-to-side movements. To depress the nucleus so as to bring its upper margin in front of instead of behind the posterior edge of the wound, where the rush of fluid had carried it, was a matter of difficulty, but this was at last overcome by introducing a sharp needle into the nucleus and pushing it down. Slight pressure being exerted behind the wound at the same time, the upper margin of the nucleus disengaged itself, and presenting through the wound, quickly came out, and the operation was completed. Every means were now taken to keep the patient quiet; he was allotted a special attendant, and as much as possible the importance of absolute rest was impressed upon him. Owing to the capsule being entirely removed—a most unexpected, rare, and fortunate occurrence in this variety of cataract operation—all fear of inflammation of the iris could be dismissed, and one's anxiety was devoted to promoting a rapid union of the wound. All went well for five days, but on the sixth night, during the temporary absence of the attendant, and in spite of all warnings, he strained greatly to relieve his bowels, with the consequence that the wound, when seen the following morning, was opened up and a bead of vitreous was presenting. Firm pressure was then applied, and bark, port wine, eggs, and stout were given to keep up his strength and to promote union. Matters again did well until the twelfth day, when in consequence of his sitting up in bed to get his tea on the previous evening, the outer third of the wound was seen to have again given way. The powers of union being thus so poor, increased stimulation by port wine, stout, bark, and food was given, and every care taken to prevent any further untoward movements on his part, with the result that on the seventeenth day the wound was again united in its whole length, and from this time onward things went well, but it was not until a month had elapsed from the operation that it was deemed safe to allow him to get up. The final result of the operation is a gratifying one. On testing his vision, four months after the operation, for distance, with a + 10 D lens, it was perfect, he being able to read at a distance of 20 feet every letter of Snellen 20; and his near vision was also perfect, he being with a + 14 D lens able to read Jaeger 1 with fair fluency. In fact, with that eye his vision was normal.

In addition to the operation being performed on a lunatic, there are other points of interest in the case—viz., the fluidity of a cataract occurring in a man aged seventy-one, the entire removal of the capsule, and the difficulty that was experienced in attaining firm union. It was the knowledge of the general impairment of nutrition common to the insane, and almost certain to be met with in any man of seventy-one, that induced me to make the incision entirely in the vascular sclerotic, and as far away as was consistent with safety from the non-vascular cornea, and the after-results showed, I think, that this was a wise precaution. Also, I am inclined to believe that the fluidity of the lens lends truth to the old man's statement that the cataract had existed for twenty years, and the dense condition of the capsule, and the ease with which it came away from its usual attachments, corroborate this. This point may be cleared up when the left cataract is extracted and its consistency known.

Liverpool.

NOTES ON HIP-JOINT ABSCESS.[1]

BY EDMUND OWEN, F.R.C.S.,
SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THERE were in the Louise ward of the Children's Hospital at the time that these remarks were put together five cases of hip-joint abscess, all of which had been subjected to the same ultimate treatment.

The occurrence of abscess in the progress of disease of the hip-joint is common enough, but the question as to what had better be done with such abscess cannot always be answered off-hand. The signs of the formation of abscess may be increasing pain, a rise of a few degrees in the temperature chart, a fulness in the upper part of the wasted thigh, and a decline in the general health of the child. But sometimes pus collects without the surgeon's attention being specially attracted to the part, and the abscess is discovered, almost by chance, as an obscurely fluctuating fulness below or in front of the great trochanter, at the origin of the adductors, or just beneath the middle of Poupart's ligament. In the first and second case the pus had probably escaped through the thin posterior part of the capsular ligament, and thence worked its way round. In the last case, a comparatively rare one, it had made its exit through the perforation in the front of the capsule by which the bursa beneath the psoas communicates with the interior of the joint.

Aspiration.—I confess that my experience with aspiration of hip abscess has not been specially satisfactory. Although the instrument used may have been a slender one, still within a few days of its employment pus has been seen leaking from the site of the puncture. In two of the five cases under consideration a disappointing leakage had thus occurred. Nevertheless, repeated aspiration should always start the treatment of hip abscess, unless the inflammatory condition be acute and the pressure symptoms severe. If the pus be thick and curdy the cannula will not serve, and other means must be employed; so also if the re-accumulation of pus be rapid and repeated puncture fail to make headway. Lastly, if aspiration be followed, as it may be, by acute local inflammation and constitutional disturbance, something more is needed.

Incision.—From one or other of the reasons just enumerated the hip-joint abscess in all five children (their ages varied from three to seven years) had to be freely incised by the house-surgeon, Mr. Lewis. From some of the abscess cavities, after the escape of pus, much curdy matter, granular débris, and shreddy material were squeezed or

[1] From reports taken by Dr. Chaffey.

Digitized by Google

scraped. The cavity was then thoroughly washed out with a solution of zinc chloride or mercuric chloride. Provision was made for drainage, and the neighbouring surface was dusted with iodoform and firmly compressed with pads of wood-wool and bandage. From time to time the cavity was again washed out and fresh pads reapplied. The drainage-tube, that useful but much abused accessory, was discarded at the earliest possible moment. These notes cannot be ended, as reports in THE LANCET so generally are, with the remark that each patient after a thorough treatment made a rapid and complete recovery. That, unfortunately, is not the way of hip cases. But this may be said, that after the evacuation of those abscesses which were unamenable to aspiration, the temperature, which had been high before, generally came down, and that which had been tolerably low before showed little or no disturbance; that the health and comfort of the child improved and the local condition greatly changed for the better; that the wound remained quiet, in some cases discharging thin pus, and in some cases dwindling into a narrow fistula; and that in one case at least the abscess wound was healed within a month.

Night screams.—In two of the five cases it was noted that after aspiration the children ceased to scream at night. Doubtless this was on account of the tension being removed from certain filaments of sensory nerves. The opinion is rather widely held, I think, that starting and screaming at night should be taken as evidence of ulceration of articular cartilage having set in. I doubt, however, if there be any direct association between these conditions. Night-startings may occur without ulceration of cartilage; and, on the other hand, extensive ulceration may exist without such startings. Moreover, ulceration of cartilage may be far advanced, and yet the signs of local and general disturbance may be but slight, the temperature-chart showing hardly any variation from the normal line.

NOTE ON INTERMITTENT ALBUMINURIA.

BY W. M. COLLINS, M.D.

I HAVE lately had under my care three cases of so-called intermittent or transitory albuminuria unconnected with organic disease, and as the subject has recently been treated by Dr. Pavy and discussed in THE LANCET, I desire, as a small contribution to such observations, to give a few particulars of these cases, with special reference to one characteristic symptom they had in common, and which, I believe, may in many instances explain the nature and cause of this disorder. I refer to the presence of large quantities of oxalate-of-lime crystals in the urine.

The patients were young persons, aged respectively twenty-five, twenty-two, and eighteen. The general symptoms, which were very analogous in each case, were nervous depression, a feeling of languor, occasional headache, derangement of the digestion, constipation, and susceptibility to cold. The quantity of urine passed was generally below the normal, the specific gravity varying from 1020 to 1030, and of a deep yellow colour. The amount of albumen varied according to the time of day the urine was passed. It was greatest between twelve and six o'clock, and diminished towards bedtime. In the early morning there was generally only a trace, or it was absent altogether. In two of the cases the albumen used to disappear completely for a few days and then reappear. Microscopic examination exhibited large quantities of oxalate-of-lime crystals along with uric acid. There were no casts. The increase or subsidence of the albumen was found to be in direct ratio to the excess or diminution of the oxalates in the urine examined. I have observed that in the cases reported by Dr. Pavy oxalate-of-lime crystals were invariably found in the urine, but no reference was made as to any probable connexion between the existence of these crystals and the albuminuria.

The following are a few brief particulars of two of the cases which came under my care.

J. D——, aged twenty-five, last May complained of derangement of the digestion, sleeplessness, depression of spirits, lassitude, and a constant feeling of chilliness. The tongue was furred, the complexion sallow and anæmic, and the gums and lips pale. The urine, which was high-coloured, depositing urates, and with a specific gravity of 1025 to 1030, was found to contain a large quantity of albumen, and this at first occasioned some alarm, but on testing the urine at different times of the day it was found to be almost free from albumen in the early morning and at bedtime, but in the afternoon there was a considerable quantity. Microscopic examination revealed large quantities of oxalate-of-lime crystals with uric acid, and there being no constitutional evidences of Bright's disease, the case was diagnosed as one of temporary or intermittent albuminuria. The patient was treated with dilute nitro-hydrochloric acid, the diet was regulated—fish and chicken being substituted for butcher's meat, and no wine allowed—and Turkish baths were taken twice a week. In a few weeks the albumen began to lessen, the oxalates diminished, and the general health greatly improved. The patient was subsequently ordered to Contrexéville, and returned home quite restored in health and without a trace of albumen in the urine, which was otherwise perfectly normal; and has since—now three months—remained quite free from any return of the albuminuria.

E. C——, aged twenty-two, came under my care last June. He complained of debility, lassitude, severe headaches, and at times a sense of giddiness and fulness in the head, great nervous depression, derangement of the digestion, and he had lost weight considerably. The urine, on being tested, was found to contain a large quantity of albumen, which varied at different periods of the day, it being always greatest in the afternoon and hardly perceptible in the early morning. Some days it would disappear altogether and then recur. Under the microscope large quantities of oxalate-of-lime crystals were seen, and these were found to be most numerous whenever the albumen was greatest. This patient was treated with small doses of dilute nitro-hydrochloric acid; the diet was regulated, all wine was interdicted, and skimmed milk was given. Subsequently the Contrexéville water was ordered to be taken twice a day. The patient soon began to improve, the albumen gradually diminished, the oxalates disappeared, and his strength increased. He went to Scotland in the autumn, and on his return he had gained 16 lb. in weight; there was not a trace of albumen to be found, and he has since remained quite well.

The third case which came under my observation was similar in all essential particulars to the foregoing.

I consider the albuminuria in these and other such cases to be due to the irritation of the kidney structure by the sharp crystals of oxalate of lime which are deposited in the tubes. Evidence in support of this conclusion is further afforded by the fact that the treatment, which was directed to prevent the formation and favour the removal of these crystals, succeeded in completely curing the albuminuria. Other causes may, doubtless, account for temporary albuminuria, such as vascular weakness and atony of the nerves, or congestion of the kidneys, concurrently with neighbouring organs, from a chill, &c. Numbers of people, too, have oxalates as a temporary occurrence, without albuminuria; but when the habit becomes fixed, I think it will be found that it is frequently the cause of this intermittent albuminuria, and may even be the precursor or predisposing cause of Bright's disease. The significance of such a symptom should therefore not be underrated, and should receive the most watchful care and treatment. In such cases the dilute nitro-hydrochloric acid in small doses, by its action on the liver preventing the formation of and breaking up the crystals of oxalate of lime, and the use of the weak, alkaline earths, such as lithia, and the Contrexéville waters, are singularly curative.

Cadogan-place.

PRESENTATION.—Dr. C. E. Monro, on the occasion of his leaving Newtown to carry on practice in the suburbs of London, has been presented by friends and patients with a handsome silver salver, accompanied with an illuminated address.

MEDICAL OFFICERS OF IRISH PRISONS.—The General Prisons Board, Ireland, have recently issued a circular with reference to the payment of fees of substitutes for medical officers of prisons during their absence. It is to the effect that when a medical officer attends as a witness before a Commission of Inquiry, or as a witness at assizes, and is paid his expenses, he must pay his substitute, as the board decline, they state, in any case, even where an allowance is conceded, any direct responsibility to such substitute.

UNIVERSITY COLLEGE HOSPITAL.

STAB IN THE ABDOMEN WITH A CARVING-KNIFE; EXAMINATION OF STOMACH, COLON, AND OMENTUM; VISCERA REPLACED; SUTURE; UNINTERRUPTED RECOVERY; REMARKS.

(Under the care of MR. BARKER.)

THE following case of penetrating wound of the abdomen is chiefly interesting from the treatment which was carried out in the case. It was not certain whether there had been a wound of the contents of the abdomen or not, neither was it known to what extent extravasation of blood might have taken place. Wound of the viscera with extravasation of contents, or decomposition of blood-clot, producing peritonitis, constitute the chief danger in these cases. Few surgeons with the power of employing full antiseptic precautions would hesitate to follow the method used here, and remedying as far as possible any such condition, if found. In the surgical records of the Americal civil war thirteen cases of incised or punctured penetrating wound of the abdomen without injury of the viscera are recorded; of these nine recovered.

L. D——, a healthy girl, aged fourteen, was admitted at about 4.30 P.M. on January 14th for a recent wound of the abdomen. She was carrying a dish downstairs at 2.30 P.M., on which was a carving-knife pointing towards herself. At the kitchen door she turned to speak to the cook, and then stumbled, when the handle came in contact with the door-post, and the blade ran into her abdomen, remaining there for some seconds before falling out by its own weight. She did not faint at the time or later. On arriving at the hospital she was examined by Mr. Barker, after careful cleansing of the wound with carbolic solution. The wound was a clean cut one, an inch long, seated two inches to the left and an inch and a half above the level of the umbilicus, close to the margin of the ribs, and consequently over the cardiac end of the stomach. On passing the finger into the slit, it was found to correspond to a deep wound in the rectus muscle, which was almost transverse. A probe was passed into the abdomen from left to right, and was felt to tilt against scybala in the transverse colon. There was but little external bleeding, though a few small clots escaped. The girl was not collapsed, and did not appear to be suffering much pain. The pulse was 130; the temperature in the rectum, 101·2°.

Judging from the extent of the wound and its direction that either the stomach or transverse colon could hardly have escaped, Mr. Barker determined to explore the abdominal cavity thoroughly round the seat of injury before any septic processes should have time to extend. The temperature and pulse at 6 P.M. seemed to indicate the commencement of inflammation. He therefore enlarged the skin wound forwards to the extent of exactly three inches, the inner end of the incision now reaching the middle line about half an inch above the umbilicus. The whole operation was done with the strictest antiseptic precautions. The rectus muscle was then seen to have been divided by the carving-knife almost completely across, only half an inch or so remaining uncut close to the linea alba. The wound gaped widely, and was partly blocked by a mass of omentum. On the latter and between the ends of the divided muscle were some small clots, which were carefully wiped away. When the whole space had been cleared, and a few of the inner fibres of the rectus had been divided to the extent of the wound on its peritoneal aspect, the omentum was drawn out and wiped clean of some remaining clots. It was then replaced, and the stomach was drawn out of the wound to a considerable extent and examined, but was found to be uninjured. Having been carefully wiped with carbolised sponges, it was replaced, and the adjacent part of the colon was pulled through the wound and passed through the fingers from side to side, until all of the transverse portion that might have been injured had been closely inspected. Finding no injury here, Mr. Barker replaced the bowel, and then sponged out the abdomen all round with small carbolised sponges. The peritoneal edges of the wound were then brought firmly into contact by six or seven stout carbolised silk sutures, including the edges of the rectus muscle and its sheath. These were cut short and remained in the wound. The skin wound was then united with seven silk sutures, except at the outer angle, where a drainage-tube was inserted. It was dusted with iodoform, and dressed with salicylic wool firmly secured with a bandage encircling the body.

There was no shock after the operation, and at 8 P.M. the patient was comfortable; pulse 100; respiration 22; temperature in the rectum, 99°. During the night the patient vomited a little, as the result of the chloroform, but was almost free of pain. The next day she was perfectly well, and remained so until she left the hospital. She required no morphia, and was in a few days anxious for abundance of food. The wound was dressed for the first time on the third day, and was found healed, without a trace of discharge. The tube was shortened to half an inch, and the same dressing applied. This was not again disturbed until the twelfth day, when the seven superficial stitches and the last bit of the tube were removed, as the wound was quite dry and healed. The deep sutures were left undisturbed. The girl was quite well from first to last, the pulse, temperature, and appetite remaining normal. As the rectus muscle had been cut across, Mr. Barker thought it better to keep the patient in bed for full three weeks, to avoid overstrain of the deep sutures. She was therefore kept on her back, with the shoulders raised and thighs flexed, until the twenty-second day, when she was allowed to get up. A week later she went home, perfectly well in every respect.

Remarks by MR. BARKER.—That the knife must have passed well into the abdomen was evidenced by the extent of the gash in the peritoneum, and that the viscera should have escaped was extraordinary. The extent of the wound in the rectus and peritoneum could not have been discovered without enlarging the skin wound, and, without examination of the viscera as above, there would have been no certainty as to their fate. The early removal of the clots and thorough cleansing of the serous surfaces probably prevented a dangerous peritonitis, which was almost certain to follow such a wound of the peritoneum made by a knife lately used for carving; and the accurate suture of the peritoneum, the rectus muscle, and its sheath prevented any chance of hernia if the patient survived the risks of the stab.

WEST LONDON HOSPITAL.

POISONING BY OXALIC ACID, FOLLOWED BY PARTIAL SUPPRESSION OF URINE AND ACUTE NEPHRITIS; RECOVERY; REMARKS.

(Under the care of Dr. DONALD W. C. HOOD.)

THE following notes have been supplied by Dr. Bailey, resident house-physician.

D. W——, aged forty-two, labourer, was admitted on June 9th, 1885. Shortly before admission he had taken half an ounce of oxalic acid mixed with hot tea. The patient stated that almost immediately he became unconscious. He was brought to the hospital at 9 A.M., being in a collapsed condition, with sub-normal temperature (97·2°); pulse very feeble (120 to 130), scarcely perceptible at the wrist; no delirium; face livid and cold; extremities cold; pupils normal; mind entirely clear; throat extremely painful; tongue with white coating on dorsum, otherwise not much burnt; almost constant retching, any fluid swallowed being immediately returned; vomit giving characteristic reaction, becoming black after standing. The patient was treated with lime-water and albumen, the tendency to collapse and syncope being kept in check by brandy and sinapisms.—2 P.M.: Quietly dozing; temperature normal; pulse 90, very feeble; retching still obstinate.—10.30 P.M.: General condition improved; pains in the throat less. Now makes complaint of great pain over the region of the bladder and right hypochondrium. Is unable to pass urine; 20 oz. drawn off by the catheter, and found to be normal.

June 10th.—Passed a fair night. Pulse 68; pain in

Digitized by Google

bladder, which does not appear to be increased by pressure; still vomits; has passed no urine.

11th.—Voided 3 oz. of urine, which was unfortunately thrown away. Pulse 78; temperature 100°. Pain in the loins. Vomited much.

12th.—Urine 3 oz., thick, straw-coloured; sp. gr. 1012; neutral; nearly solid on boiling; deposit of blood-corpuscles and large granule cells; no casts. Vomiting continues the most troublesome symptom. The abdominal pain is less.

13th.—Urine 3 oz., character same as last. Vomiting more troublesome; everything taken by the mouth is thrown up immediately. On one occasion about a pint of black fluid (altered blood) was ejected. Ordered to take no food by the mouth; to be fed entirely on nutritive enemata.

14th.—Feels very weak; irritability of stomach much better. Retains enemata well. There is marked pain over both renal regions, and slight swelling of legs. Tongue almost denuded of epithelium.

16th.—Since the last note he has passed more urine, as much as 24 oz. during the night; it is still highly albuminous.

18th.—Since the 13th he has been fed entirely by the bowel. To-day he was ordered a little milk, which was swallowed without difficulty or pain, and was retained. Urine normal in quantity.

19th.—Quantity of urine 70 oz. during the night.

20th.—Urine 144 oz. during the twenty-four hours; it is still highly albuminous; examined for urea, it was found that an average of 700 grs. per day are being passed; the deposit consists of granular cells; casts containing granular cells, others simply granular, and others hyaline.

25th.—Since last report the patient has been passing very large quantities of urine, from 150 oz. to 120 oz., in the twenty-four hours; the albumen is gradually decreasing, as are also the deposits. His general health is much improved. He retains all food, and feels stronger and better in every way.

July 3rd.—Discharged well. No trace of albumen has been detected in the urine for the past three or four days. The patient expressed himself as feeling strong and well.

Remarks by Dr. HOOD.—In the cases of poisoning by oxalic acid to which I have referred, I can find no mention of the kidneys being subsequently affected. In the above case the suppression of urine first noticed was more apparent than real. The patient could take no nourishment, and vomiting was constant. But that the kidney received the brunt of the attack was clear by the large amount of albumen which appeared, and which rendered the specimen of urine examined all but solid. Blood-exudation corpuscles, pus, albumen, and casts, pronounced a definite nephritis, which cleared up as rapidly as it commenced, convalescence being marked by extreme diuresis. With regard to the treatment, the fact that for five days the stomach had complete rest, the patient being supported during that time entirely by nutrient enemata, is worthy of note. As in many other cases of poisoning by this salt, the onset of symptoms was very sudden. My patient stated emphatically that he became almost immediately unconscious.

QUEEN'S HOSPITAL, BIRMINGHAM.

CASE OF MALIGNANT DISEASE OF CÆCUM; NECROPSY.

(Under the care of Dr. SUCKLING.)

FOR the following notes we are indebted to Mr. J. Griffiths Whittindale, house-physician.

J. H——, a male, aged fifty-seven, was admitted on Aug. 10th, 1885. Family history good; father died at the age of eighty-four; mother aged eighty-six. Is a shoemaker by trade. Some years ago he used to suffer from cramp and spasms, but had never had any acute illness. About nine months since he fell downstairs and injured his right side, and this was followed by diarrhœa for two months. Seven months ago he noticed pain in the right lumbar and iliac regions; these pains were sharp and of a shooting character. Soon after this he noticed a lump in the right iliac region, and this had slowly increased in size up to the present time. Bowels had been regular, and he had not passed blood.

On admission the man had an anxious and pinched expression, and was evidently emaciated. He complained of constant pain in the right iliac fossa and pain and difficulty in micturition. Said he had been losing flesh rapidly. Cardiac and respiratory systems normal. On examination of the abdomen, a tumour about the size of a cricket-ball was found in the right iliac fossa extending upwards into the right lumbar region. The growth was firm and fixed, not moving with respiration, and was tender on pressure; it caused a visible prominence. The femoral glands on both sides were enlarged. The tumour was slightly irregular on its surface, extending downwards to Poupart's ligament, upwards to the level of the umbilicus, and inwards to the outer edge of the rectus abdominis, with dulness on light percussion and resonance on heavy percussion. Right testicle painful and enlarged. Temperature normal. Weight 8 st. 3 lb.

Aug. 20th.—Growth has not materially increased in size since admission, and the pain is not so severe. Bowels open daily, stools being normal and containing no blood. During the past week there has been a rise in temperature, which now ranges from 100° to 101°. Weight 8 st. 1 lb.

30th.—General condition of patient has improved, but the temperature still varies.

Sept. 8th.—No pain for some time and no increase in size of growth. Patient was discharged to-day at his own request.

Oct. 10th.—Readmitted to-day. He says that for about a week after his discharge he felt very well, but the pain then recurred and has been very severe since, shooting down to the scrotum and through to the back. Three weeks ago diarrhœa came on and has continued, and a fortnight since he passed blood in his motions. Complains of loss of appetite and flatus. The tumour has increased in size. Temperature 100°. Rectal examination revealed nothing abnormal. Weight 7 st. 11 lb.

13th.—Pain has been very acute. Diarrhœa continues. There is increased tenderness on pressure over the tumour.

20th.—Complains of sickness in the mornings. Growth increasing in size in lumbar region. Temperature varies from 99° (morning) to 101·8° (evening).

30th.—Tumour growing rapidly. No pain now. Marked anæmia. Epigastric veins enlarged from pressure on vena cava. Patient has appreciably lost flesh since admission, but weight remains the same, probably from increased size of growth. Slight dulness on percussion, increased vocal fremitus, and some fine râles found at right apex to-day.

Nov. 14th.—For the past two days he has vomited after everything he has taken. The stomach is dilated, and he is much more feeble.

23rd.—There is now œdema of both ankles. A bed-sore has developed over the coccyx. Patient takes very little nourishment, and seems to be sinking.

25th.—No improvement. Temperature still high.

27th.—Much worse. Growth now extends beyond the middle line of the abdomen, and has been growing rapidly for the past few days. Complains of pain in the left side, and on auscultation friction sound was heard and dulness on percussion found.

29th.—Died this evening.

Treatment.—This resolved itself into treating symptoms as they arose. Hypodermic injections of morphia were given to relieve the pain and bismuth to control the vomiting. He was put on a stimulating diet. Small doses of cod-liver oil were tried at one time, but he could not retain it.

Necropsy.—Thorax: The left pleura contained some 6 oz. of clear serum. Left lung normal. There were two small cavities in the apex of the right lung, about the size of a marble. On opening the abdomen two large masses were seen, one occupying the right iliac and lumbar regions, and another lying over the spinal column. The small intestine was traced fairly easily down to about a foot from its termination, where it became involved in a mass lying over the spinal column. On making a section in this part the gut was seen to be much diminished in calibre, its walls enormously thickened, and intimately blended with what appeared to be the mesenteric glands, though such a quantity of seemingly scirrhous material was present that it was impossible to dissect the parts satisfactorily. The ileum could not be traced past this large mass. The ascending colon was next found and traced downwards, and was seen to lead to a cavity large enough to contain the whole hand; this was firmly associated with the mesentery and abdominal wall, and in separating it from the latter a large quantity of fetid liquid fæces escaped through accidentally rupturing the wall. This large intestinal expansion, so to speak, was apparently the cæcum, or rather its anterior wall was formed by the cæcum, and behind it seemed that the wall was formed by the iliacus muscle, as no trace of intestinal wall was found. Throughout the

Digitized by Google

abdomen small nodules of malignant growth were found, being especially abundant over the kidneys and diaphragm. The larger growth was also blended with the wall of the bladder. Some nodules were also found attached to the coils of the ileum and around the rectum. No secondary growths were found in the liver or spleen. On removing the right kidney a large quantity of urine was forcibly ejected, and on opening the organ it was found to be hydronephrotic, the pelvis being much dilated, this probably being caused by pressure of the cæcal mass on the ureter. The same condition was found on the left side, apparently from pressure by mesenteric glandular enlargement on the ureter. Microscopical examination of the growth by Dr. Gilbert Barling showed the growth to be a carcinoma.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Intra-cranial Tumours.—Thinning of Skull from Cerebral Tumour.—Cancer of Body of Stomach.—Cylindrical Cancer of Humerus.—Syphilitic Hepatitis and Pneumonia in an Infant.—Dermoid Cyst of Tongue.—Epithelial Tumour of Skin near the Rectum.—Aneurysm of Aorta and Aortic Valves.—Multiple Intussusception.

AN ordinary meeting of this Society took place on Tuesday last, Dr. Bristowe, President, in the chair.

Dr. BEEVOR showed a Tumour of the Upper Surface of the Cerebellum that grew forwards between the optic thalami, flattening the corpora quadrigemina and compressing the right optic thalamus, crus cerebri, and right superior cerebellar peduncle, causing left hemiplegia, fixation of eyes, staggering gait, priapism, fixed pupils, headache, vomiting, and optic neuritis; it was a psammoma. The second case was that of a man aged forty, in whom two tumours were present on either side of the medulla: one the size of a hen's egg on the left side, compressing and absorbing the under surface of the left lobe of the cerebellum, and pressing on the left side of the pons, the left fifth, seventh, eighth, and ninth nerves especially being destroyed; on the right side, in the angle between the medulla, pons, and flocculus, was a tumour the size of a hazel-nut, and pressing on the seventh and eighth nerves. The patient was stone deaf in both ears, and blind in both eyes; no absolute paralysis, but general weakness and double optic neuritis. The third case was that of a boy aged twelve in whom the tumour, a glioma, occupied the right side of the pons and the medulla, causing distension of parts and conjugate deviation of the eyes, with facial paralysis on both sides. The fourth case was a boy aged three months with a tubercular tumour of the right half of the pons and the medulla, causing left hemiplegia, complete right facial palsy, and conjugate deviation of both eyes to the left. Another specimen was shown of a tumour pressing on the left side of the pons and the cerebellum, producing staggering to the left and deafness of the left ear.

Dr. GEORGE OGILVIE exhibited a Tumour of the Right Hemisphere of the Cerebellum taken from a woman aged twenty-one. The case has been fully reported in Part 31 of *Brain*. Blindness, deafness on the right side, vertigo, staggering to the right, vomiting preceded by occipital headache and followed by unconsciousness, very feeble pulse, sensation of cold in the legs, atrophy of both optic discs, but no incoördination, were the chief symptoms. The tumour had a cartilaginous appearance, and was the size of a hen's egg; it had grown from the dura mater of the right side of the posterior fossa, and was a tubercular mass. The second case was that of a large Tumour of the Left Optic Thalamus, and occupied the posterior half of the left lateral ventricle; it came from a married woman aged thirty-nine. The symptoms were persistent severe frontal headache, noises in the ears, blindness, vomiting, giddiness, tendency to fall backwards and to the left, and impaired intelligence. The symptoms began four months after her last confinement. Maniacal attacks with hebetude for six weeks before death were also observed, as well as atrophy of both optic discs and loss of knee-jerks. Death followed an attack of double pneumonia. The tumour involved the posterior two-thirds of the left optic thalamus. The consistence was soft, and hæmorrhages were present in the gliomatous tumour.

Dr. HALE WHITE showed a series of specimens to illustrate the condition of skull met with in certain patients who die of tumour of the brain. The bones were soft and light, very thin, and transparent when held up to the light, which proceeding, owing to their tenuity, shows in the recent condition the vessels as a beautiful arborescent network. The thinness of the frontal, parietal, and occipital bones is in advanced cases about the same as that of cardboard. There is no bone in the skull which may not be altered in this manner; but the change, if it exist, is always found in the bones of the vertex, and in extreme cases in those of the base also; thus in one of the cases shown the petrous bone was affected, and its abnormal thinness gives a cribriform appearance and has laid open the tympanum. The bone, however, always remains hard. There is nothing noteworthy on the external surface, but the internal is roughened like sand-paper. In none of his cases was the tumour itself in actual contact with the skull. There is no doubt that this condition of bone is due to increased intra-cranial pressure. The growth of the tumour and ventricular distension are two causes of the increased pressure. The direction of the pressure is so variously modified that it is impossible to calculate accurately, for some tumours simply replacing brain substance cause no increase of pressure. As a rule the tumour is large, or ventricular distension great, where the thinness of bone obtains. The condition is rare in young children, for increased pressure causes the sutures to separate. There is little or no likelihood of the condition being mistaken for any other affection of the bones. There is never any thinning or absorption of the membranes—just as happens when an aneurysm causes absorption of the vertebræ by pressure, the bone disappears long before the inter-vertebral disc. Pain is such a constant symptom of cerebral tumour that it is impossible to decide whether the pain is particularly increased when the bones are becoming atrophied. Occasionally the pressure seems to set up some inflammatory action in the dura mater, for it may be seen to be covered with fine granulations. In reply to Dr. Bristowe and Dr. Carrington, Dr. White said that the symptoms had existed for some months in the case where the skull was thinnest. The thinning was due to general pressure inside the skull. The skulls referred to were preserved by Dr. Wilks and Dr. Moxon as illustrating the early stage of the thinning.

Dr. CARRINGTON exhibited a specimen of Cancer of the Body of the Stomach taken from a man fifty-seven years of age, in whom nine months before admission a profuse attack of hæmatemesis set in. Other symptoms were pain after food, vomiting, emaciation, debility, and ascites. Paracentesis was performed, and then the liver dulness was found to be diminished. At the necropsy one or two secondary nodules of cancer were found in the puckered great omentum; the œsophageal walls were hypertrophied; the pylorus and cardia were healthy, but the stomach was contracted, its walls thickened, it measured six inches by three, and had the appearance of an indiarubber bottle; there was no ulceration; the liver was very small, soft, and flabby, with wrinkled capsule; on section the lobules were ill marked. There was no obstruction of the vessels or ducts. The stomach was universally infiltrated with small round cells, with a superficial layer of undoubted carcinomatous growth. The hepatic cells were atrophied and fatty. In reply to Dr. Sainsbury, Dr. Carrington said vomiting continued till the last stage of the disease; and to Dr. Bristowe, that the disease lasted ten months.—Mr. BUTLIN referred to a similar case in the Royal College of Surgeons museum, and also to an œsophagus and scirrhous carcinoma of the bladder, in which the shape of the parts was maintained. Where hollow organs were affected he found it as Dr. Carrington described.—Dr. BRISTOWE had also seen a similar stomach (? carcinomatous).

Mr. JONATHAN HUTCHINSON, jun., showed specimens of Cylindrical Cancer of the Humerus. The patient, a Jewish lady aged fifty, was treated by Sir Andrew Clark for "rheumatic pains" about the left shoulder, which had followed a fall. After some little time a swelling developed in the upper third of the arm, and, Sir James Paget agreeing as to the advisability of an operation, Mr. Hutchinson made an exploratory incision to the bone, and found a small tough white growth adherent to the periosteum, near the deltoid insertion; during the manipulation the bone snapped. Amputation at the shoulder-joint was performed. The part healed well, but soon after the patient suffered from attacks of abdominal pain, she became more and more asthenic, and died some six months after the operation. The tumour had

Digitized by Google

certainly started in the medulla of the humerus, had crept through some minute canals to the periosteum, and from this had invaded the deltoid insertion and the surrounding fat; it probably had existed some five months; it filled about two inches of the medullary cavity; above this the medulla was very soft and congested, the head of the bone appearing quite healthy. The interest of the case lies in the microscopical structure, which in the central part of the tumour consists of regular cylinders or tubes, lined with one or more layers of cubical or cylindrical cells. The central cavity is formed by the fusion of vacuoles developed in the interior of the masses of cells, finger-like processes of which run in amongst the surrounding tissues. At parts the tubules resemble closely normal renal ones. It is tempting to try to regard the growth as a very unusual primary one of the bone—clinically it appeared to be such; it followed a blow on the part, and its method of spreading would agree with Sattler's illustration of the early stage of cylindroma. Sattler himself is doubtful as to the true nature of this form of tumour, but thinks the cells of epithelial rather than connective-tissue nature; Billroth describes cylindroma both under cancer and sarcoma; Mr. Butlin regards it as a sarcoma. In Mr. Butlin's rare case the tumour was soft and grew from the posterior ligament of the knee-joint. Paget mentions a case occurring in the humerus; most of the others have been found in the orbit or the parotid gland. But the ultimate structure of the present tumour is not that of true cylindroma, and a more natural explanation is that it was a secondary cancer, the primary one being, perhaps, situated in some part of the alimentary tract. There was no family history of tumours; no tumour certainly existed in either breast, nor was there any evidence of intestinal obstruction. It is worth noting that in 1863 Dr. Tyler Smith removed an ovarian tumour from the patient; the long interval (eighteen years) which elapsed, however, almost puts out of the question this being the primary growth. The following case throws some light on the matter. The patient, a man aged fifty-one, was admitted into the London Hospital in March 1885, under Dr. Sutton, suffering from pain in the hepatic region, which he attributed to a severe chill. Jaundice rapidly supervened, he lost flesh, and had diarrhœa alternating with obstinate constipation. In August ascites came on and he was twice tapped, eleven and thirteen pints of fluid being drawn off. At the post-mortem the liver was found to weigh 6¾ lb., and was firm; the gall-bladder was much dilated behind a light band; the capsule was speckled with white spots. Close to the small bile-ducts were found in various parts tubules and small cysts which resembled dilated ducts, but which were probably secondary growths which had been developed by means of the lymphatics from a small primary nodule at the pylorus. The lungs contained many small growths precisely similar to those described already in the first case; the pancreas, spleen, and kidneys presented nothing worthy of note. The perfect resemblance to gland tissue must serve to place this form of tumour amongst the most highly developed cancers.—Mr. BUTLIN referred to his case of cylindrical-celled carcinoma, which began in a rare situation in the ham. Cases of carcinoma of bone had been frequently recorded and it was reasonable to suppose (no primary source of the carcinoma being found) that some of the tumours were primary in the bone.—Mr. R. W. PARKER said that some ovarian tumours he had examined had the same cylindrical-celled characters as Mr. Hutchinson's specimen; he still thought that such osteal tumours were of secondary nature.—Mr. SUTTON considered that an epithelial tumour in the centre of the bone was inexplicable as a primary growth.—In reply, Mr. HUTCHINSON said that an interval of eighteen years had elapsed since the ovariotomy; so he could not agree to Mr. Parker's suggestion that the primary source was the ovarian tumour.

Mr. C. J. SYMONDS showed specimens of Syphilitic Disease of the Liver and Lung taken from a child one month old, in whom the first sign of the congenital mischief was a squamo-tubercular syphilide. The liver was enlarged, firmer than natural, greyish in colour, and uniform in consistence. It was uniformly infiltrated with a fibro-cellular growth; the liver cells seemed to be destroyed by the pressure of the new growth; much resemblance to hypertrophic cirrhosis was noted, but the appearances of a duct formation were absent. In the lung was a lump three-quarters of an inch across, solid, of greyish colour—an example of the white hepatisation of Virchow.—Mr. VICTOR HORSLEY considered that the disease was not rare, and Dr. ANGEL MONEY had made four examinations in which the syphilitic disease existed in the liver and lung.

Mr. STEPHEN PAGET brought forward some dermoid cysts. Mr. Sutton regarded them as not due to involution of epidermis, but to some change taking place in or around a minute duct in the embryo, called the lingual duct, which was the remains of a space that exists in the embryo between and beneath the halves of the tongue; when these halves are joined in the middle line the space is reduced to a minute canal, which runs down from the foramen cæcum, behind the tissues from which the hyoid bone is afterwards developed, and divides at its lower end into two follicles from which the thyroid gland is developed. If the lower part of this duct, the part below the hyoid bone, be not completely obliterated, it may become the starting-point of accessory thyroids, or may persist as a fine canal between the hyoid bone and the front of the thyroid gland; if the upper part of the duct be not completely obliterated, it may, Mr. Sutton says, be the starting-point of a dermoid cyst under the tongue. Mr. A. Barker described these cysts in Vol. 16 of the Clinical Society's Transactions. The cyst wall of Mr. Paget's specimen showed masses of granular black pigment in the rete Malpighii; also warty epithelial growths projected from the cyst wall. The cyst came from a girl aged five; the fluid in the cyst was very fetid.—Mr. SUTTON had advanced the notion that these teratoid and dermoid tumours were prone to develop in the neighbourhood of obsolete canals, and considered that subsequent research confirmed him in this view.—Mr. BUTLIN said the cyst was an abscess for all practical purposes.—Dr. BRISTOWE asked whether the tumour occurred exactly in the middle line.—Mr. PAGET replied in the affirmative.—Mr. HORSLEY said that in Mr. Barker's case the tumour was situate between and beneath the genio-hyoids.—Mr. BUTLIN remarked that the cysts occurred in two sites, between and outside the genio-hyoids.

Mr. CLUTTON exhibited a specimen of Epithelial Tumour which he had removed from a woman aged sixty. She came as an out-patient to St. Thomas's Hospital for some large sebaceous tumour of the scalp, and only incidentally mentioned that she had what she considered to be a similar tumour near the anus. This had been noticed two or three years, and had lately become rather painful. It was thought to be an abscess and was incised. Although fluid which looked like pus was evacuated, the tumour steadily increased in size. The patient was therefore admitted into hospital and the growth removed. It was situated quite close to the anus, but the mucous membrane of the bowel appeared to be free and was not exposed in the operation. The interest of the case chiefly rested on the naked-eye appearance of the cut surface of the tumour and its microscopical characters. The specimen, mounted in a bottle, looked as if there had been a central cystic cavity which had been subsequently filled with new growth. The cut surface, when examined with a hand glass, showed a number of small globular cysts scattered all over the solid parts of the tumour. The microscopical sections which were exhibited proved that the solid masses were epithelial, and that the small globular cysts had resulted from their mucoid degeneration. Some drawings were shown which suggested that the tumour had originated by epithelial in-growths from the skin. Each column was lined externally by a layer of columnar epithelial cells, and contained, internally, spheroidal cells, but no lumen. In the more advanced part of the growth, at some little distance from the skin, these had undergone mucoid degeneration, a condition which might possibly be explained by their proximity to the mucous membrane of the rectum. The bud-like processes from the rete Malpighii were not unlike those seen in the early stage of rodent ulcer.

Dr. SAMUEL WEST exhibited specimens of Aneurysms of the Aortic Valves and Pouches of Valsalva. The first was taken from a man aged thirty-seven, who had had rheumatic fever twice and a sudden attack of dyspnœa. The third specimen was interesting, for the aneurysm was developed from two valves which had previously fused. The fourth specimen was an aneurysm of a pouch of Valsalva and the anterior cusp of the aortic valve; the aneurysm had ruptured into the right ventricle. The case was that of a man aged thirty who had had rheumatism.

Mr. D'ARCY POWER showed a specimen in which the intestines were intussuscepted at two points: the ileo-cæcal valve, where it was two inches in length, and in the transverse colon in the reverse direction. In both cases the intestines

Digitized by Google

were glued together by recent lymph, but in the upper only was the intestine gangrenous. The occurrence of intussusception in a reversed direction appeared to be a very rare event.

The Council of the Society nominated the following gentlemen to form a committee to report on the specimens of Intra-cranial Tumour:—Dr. Beevor, Dr. Hadden, Dr. Ormerod, and Mr. Shattock.

The following card specimens were shown:—Dr. Norman Dalton: A Tumour of the Fourth Ventricle, causing Diabetes. Dr. S. West: Abscess of Gall-bladder, with Pus in Portal Veins. Dr. Hadden: (1) Intestine in Lymphadenoma; (2) Malignant Disease of both Supra-renal Bodies. Dr. Turner: (1) Syphilitic Ulceration of Trachea opening into Superior Vena Cava; (2) Conjoined Kidneys and Unicorn Uterus. Mr. J. Poland: (1) Amputation Stump at Knee-joint; (2) Dislocation of Knee-joint. Mr. E. H. Fenwick: Atresia (? congenital) of Orifice of Bladder, with Cystic Kidney. Dr. Haig: (1) Large Intra-pericardial Aneurysm of Aorta; (2) Intussusception from a Child aged four months.

CLINICAL SOCIETY OF LONDON.

Universal Alopecia.—Hysterical Pyrexia.—Meningitis of Obscure Origin.

AN ordinary meeting of this Society was held on the 12th inst., Mr. Thomas Bryant, F.R.C.S., President, in the chair. The papers read were of great interest, and evoked considerable discussion.

Dr. W. T. TYSON read a paper on three cases of Universal Alopecia, with remarks. Case 1 was that of a labourer aged forty. The family and personal history were negative in their character. The cause of his trouble seems to have been a money difficulty; for three months and a half this preyed upon his mind, and at the end of this time the hair on his head began to come out, and was all gone in four days. In a day or so later the rest of his hair began to be shed, and in four days—or in ten days from the commencement of the first shedding—the whole of the hair of the head, face, chest, body, and limbs had entirely disappeared. At the present time there is not a single hair to be seen anywhere. The hair was particularly thick and strong before the calamity; the colour was chestnut. He is a strong and active man. Case 2 was that of a shoemaker aged forty-four. Seven years ago his hair began to come out, and in one fortnight had all completely disappeared. He has never had any hair since. There was no syphilitic history. The cause, he alleges, was that two or three days previous to the loss of his hair he was sleeping at the top of the house, when, while in a sound sleep, he was suddenly awakened in a great fright by a tremendous clap of thunder. Simultaneously with the fall of his hair he lost the nails of the great toes and thumbs. The colour of his hair was light brown. He is a healthy and strong man. Case 3 was that of a billiard-marker aged twenty-one. In April, 1884, the hair began to come out in spots over the head, and in one month he had lost his hair over the whole of the body, except a few downy ones on the top of the scalp. Now there are to be seen a few hairs at the back and side of the head. The colour of the hair was dark brown and very thick. There is no history of syphilis. He is a well-built man. One month before his loss he was thrown violently from his horse upon his head. Since the accident his memory has been defective at times. These cases were brought forward as supporting the neurotic origin of the universal form of alopecia areata, and also to uphold the view that clinically there are two distinct classes of the disease, commonly called alopecia areata. The characteristics of this class of case were:—The affection begins in the scalp, not necessarily in spots, and spreads rapidly until the whole hair of the body is lost. It occurs in adults, but not always in young adults, as has been stated. The prognosis is not good, and it seems to become worse as age advances. The starting-point of the disease can often be traced to a neurotic cause. The above class of alopecia areata contrasts strongly with that ordinarily met with. Here the characteristics are that the disease begins in youth, in scattered bald patches on the scalp, and is confined to this portion of the body. The prognosis is good, the complaint lasting seldom longer than a twelvemonth. No cause is known.—Mr. BRYANT considered it remarkable that a small provincial town should furnish three such cases. He narrated a case in which mental shock appeared to induce the disease. Two young ladies were terrified at the sight of a dead body being dragged from a canal; one, who recovered, developed acute jaundice, and the other universal alopecia, which remained until her death four years later.—Dr. S. MACKENZIE considered that there were all stages between the local and the universal forms of alopecia. The presence of micro-organisms could be accounted for on the hypothesis that a disease of the skin formed a suitable nidus for the development of organisms. The rapidity with which the alopecia occurred in Dr. Tyson's cases negatived the parasitic view for his cases. Recently Dr. Mackenzie had known a case of symmetrical morphœa associated with alopecia, and he had seen several examples of neurotic disease thus associated.—Dr. TYSON could not agree with Dr. Mackenzie that the difference between the universal and local forms of the disease was one of degree: the local forms occurred mostly in children, and tended to recover; whereas the universal variety mostly occurred in adults, and did not recover.

Dr. HALE WHITE read a paper on a case of Hysterical Pyrexia. A girl aged eighteen was admitted into Guy's Hospital on Aug. 10th of last year, suffering from pyrexia, pain in the abdomen, and diarrhœa, the latter symptom being due to the abundant purgatives which had been given. Previous to admission the pain had been referred to the right iliac region; on the above date it was referred to the left. The temperature varied from 105° to 99·2°. She was readmitted on Sept. 9th. Her mother said she had returned to her work, but on the 8th was suddenly seized with pain in the left side. On readmission the face was flushed, the skin hot and dry; frontal headache; no physical signs anywhere; no evidence of zymotic disease. She complained of pain and tenderness on the left side, midway between the ribs and crest of ilium, but she never twice located the pain in the same place. If her attention was engaged she allowed the freest manipulation without wincing. At first she protested that she could not sit up and could not lie on the left side, but in a few minutes, when her attention was distracted, she did both these. There were a few vaginal cells in the urine, and a trace of albumen, but not more than the pyrexia would explain. The abdomen was so retracted that it was impossible there could have been enlargement of any viscus without its having been felt; peritonitis was also out of the question. The temperature varied between 105° and 98·8°. On September 13th the temperature was normal, and so remained till the girl's discharge. The author pointed out that the patient was undoubtedly hysterical, for the whole characteristics of the pain showed it to be subjective. The most careful examination failed to discover any physical cause for the pyrexia, nor was there evidence to show that it was due to a zymotic disease; not even typhoid fever would explain two such short, erratic, but severe attacks. If the temperature were due neither to inflammation nor a zymotic disease, it must have been due to direct affection of the nervous system, but there was no evidence that injury, growth, or inflammatory action affected the nervous system, therefore the affection of it must have been functional. Not only can the diagnosis be arrived at in this exclusive method, but the following features in the case were characteristic of hysteria: the variability of the temperature both diurnally and generally, the other hysterical symptoms, and the age and sex of the patient. It was pointed out that none of the patient's symptoms militated against the view that the pyrexia was hysterical. The cells in the urine were vaginal; the albumen and delirium were pyrexial. Rigors have been described in other cases of hysterical pyrexia. The reason why hysterical pyrexia was not more recognised was because it was not sufficiently realised that functions over which the will has no control may be hysterically affected, and also that the temperature of the body is directly under the control of calorific nerves which proceed from the cortex of the brain to the muscles; these nerves perpetually inhibit the temperature of the body. Bearing these two facts in mind, there was no reason whatever that the thermogenetic actions of the body should not be perverted, nor was it more extraordinary than hysterical ischuria, vaso-motor paralysis, &c. A brief abstract was given of all the cases of hysterical pyrexia hitherto recorded, and from these it was found that the chief symptoms of this disease were—firstly, it always occurs in girls; secondly, they are often otherwise hysterical; thirdly, they are always of an age at which hysteria is common; fourthly, ovarian pain and tenderness are often present; fifthly, rigors may be present; sixthly, other symptoms more or less connected

Digitized by Google

with the temperature are often accompaniments of it—viz., delirium, rapid pulse, flushings, a trace of albumen, but any one or all may be absent; seventhly, the characteristics of the temperature are, its erratic behaviour, the temperature also varying in different parts of the body.—Dr. W. H. DAY spoke of the case of a lady, aged fifty-six, who had some unexplained fever which he regarded as of neurotic origin.—Dr. SAVAGE said it was exceptional to get an increased temperature in asylums unless inflammatory visceral disease were about to develop. Cases, however, before admission into asylums, occurring in hysterical women, not unfrequently presented a temperature of 102° or 103°, with irregular course. Some of the cases developed acute delirious mania, and some recovered. He had taken the temperature of the scalp in many instances, and found it not to be above 99° in cases of so-called "brain fever," but a temperature of 104° in the axilla might be observed in the same cases. He suggested that an investigation of the relative temperatures of the head and body might prove of considerable value. Lurking disease of the lungs, such as a patch of pneumonia or tubercle, might, it must not be forgotten, fail to reveal any other symptoms than pyrexia, and so caution was necessary in connexion with the subject of "hysterical" pyrexia.—Dr. GOODHART considered that there was some objection to the term "hysterical," and preferred to speak of "neurotic" pyrexia.—Dr. B. O'CONNOR related a case in which there was dulness of one side of the thorax.—Dr. BRISTOWE briefly related two cases that have been published in full in "Brain." Both occurred in women. The development of ophthalmoplegia externa was followed by hemianæsthesia of all the senses; then hemiplegia and rigidity supervened, and later on epileptiform fits. There was an almost persistent fever, which varied from 97° to 103°. A year or two before there was exophthalmic goitre, which subsided some time before the fatal issue. After death the cerebral and other viscera were found to be healthy. The second case was still living and almost exactly the same, but the fever showed itself first before the onset of the fits, when the temperature rose to 102° or 105°.—Dr. HALE WHITE said the time of life, the sex, and other associations of hysteria warranted the use of the term "hysterical pyrexia." Neurotic pyrexia had a wider significance, and included cases of pyrexia due to cerebral hæmorrhage, &c. As examples of death from functional disease he regarded Dr. Bristowe's cases as of much value.

Dr. GOODHART read notes of cases of Meningitis of Obscure Origin. A young lady aged eighteen, of exceptionally good health, was much affected by an offensive smell in a house which she visited, and from that time became ill. The symptoms ultimately developed into well-marked cerebro-spinal meningitis, with vomiting, paralysis of the recti muscles of the eyeballs, severe headache, stiffness of the neck, tremulousness of the muscles, and death on the nineteenth day. There was no necropsy. Two children, one of four years, the other one year and a half, under the care of Mr. Atkins of Plumstead, had measles, and on convalescing suffered a relapse, on which the temperature rose, the head became retracted, the mental condition apathetic or comatose, and rigid spasm affected the extremities at intervals; in the elder child there was optic neuritis. Both cases recovered, the infant rapidly, the elder child after an illness of five or six weeks, and she remains permanently deaf. The next case is that of an infant four months old, brought to the Evelina Hospital for rapidly recurring convulsions and high temperature; it was admitted, and two ten-grain doses of bromide of potassium administered by enema. The convulsions ceased within twenty-four hours, but the child remained with retracted head, oscillating temperature, double optic neuritis, and momentary left-sided spasm when touched. There was no evidence of any disease of the ear during life, but after death the middle ear contained pus on both sides; there were suppurative meningitis of the right half of the brain and thrombosis of the right lateral sinus. The fifth case was that of a widow lady, aged fifty, under the care of Dr. Herbert Evans, of Hampstead. After a time of much anxiety and fatigue in nursing a relative she began to feel cold and ill; intense headache and pain in the back and paralysis of the external recti of the eyeball supervened, and a moderate amount of optic neuritis. She was treated at first with free nourishment and tonics, but without relief, but she decidedly improved under iodide of potassium and perchloride of mercury, although only slowly; the illness lasted three or four months in all. Each of these cases raises several issues as regards its origin. In the first, although it is impossible, in the absence of a necropsy, to exclude with certainty either tubercle or internal otitis, yet on the whole the facts seem to favour a septic origin. The three children, although two recovered, may all of them have been subjects of internal otitis; but cerebro-spinal fever after measles, the view favoured by Mr. Atkins, is equally possible in the case of the two. The fatal case was advanced particularly to enforce the obscurity that exists during life in many cases of otitis interna, and Dr. Goodhart wished particularly to gain the experience of aural surgeons in this matter. His own experience did not allow him to think that the disease was to be diagnosed during life by the mere alterations in the appearance of the membrana tympani, nor yet that the post-mortem appearance justified the belief that incision of the membrane would be of any real service. It was contended that these cases supported the opinion maintained for the first case—viz., that meningitis, idiopathic in a sense, is probably less grave than modern doctrines seem to teach, inasmuch as there is evidence to show that the risks of ear trouble are chiefly dependent upon superadded external conditions, and that in all probability the chronic ear disease is the open door, rather than the actual weapon by which the meningitis is inflicted. The last case still remained obscure.—Dr. F. L. BENHAM related the case of a child who had several symptoms of meningitis after measles, and was slowly recovering; he regarded the case as one of "functional" disease.—Dr. W. H. DAY said that otitis was the commonest cause of meningitis, and related several cases illustrative of the variety of clinical aspect of tubercular meningitis.—Dr. BRISTOWE considered that in the meningitis of young children recovery might not unfrequently ensue. Suppuration of the middle ear as a precursor and cause of meningitis he confessed himself sceptical about; he would not deny that it occurred, but was inclined to think that meningitis and otitis were the results of the same cause, and it was doubtful whether the ear disease was ever primary. He expressed his belief in the possibility of recovery from tubercle of the brain, and related the case of a girl who had all the signs of tubercular peritonitis; headache, double vision, and paralysis of the external recti supervened, when the abdomen became rather rapidly well. The patient ultimately made a fair recovery, though some loss of memory was still present.—Dr. C. WEST drew a sharp and fast distinction between simple and tubercular meningitis, confessing that the former might own septic causes, and might originate from eruptive fevers, and especially measles. In his belief, simple meningitis might be recovered from not unfrequently, and occasionally cerebral tubercle also. Tubercular meningitis rarely had a pyrexia of more than 101° or 102°, and this fact he regarded as of diagnostic importance. He was disposed to adopt Dr. Bristowe's point of view of the concomitance of otitis and meningitis.—Dr. SIDNEY PHILLIPS had watched a case of purulent cerebro-spinal meningitis following measles, without otitis, and the diagnosis was confirmed by a necropsy.—Mr. R. J. GODLEE had been told by Mr. Barker that the presence of muco-pus in the middle ear was an almost physiological occurrence, and asked Dr. Goodhart what his views were on this point.—Dr. GOODHART, in reply, believed that the presence of muco-pus in the middle ear was a very common condition, but not pure thick pus. Whether there was any causal relation between meningitis and otitis it was difficult to say with certainty. He considered there was abundant evidence to show that actual simple meningitis could be recovered from, and was inclined to think that even the tubercular form might terminate favourably.

The following living specimens were shown:—Dr. Stephen Mackenzie: Two cases of Unilateral Paralysis of the Tongue, Soft Palate, and Vocal Cords; and cases of Alopecia Areata in three members of one family. Mr. T. Cooke: Symmetrical Gangrene of the Fingers (? Raynaud's disease). Mr. Godlee exhibited a pathological specimen showing Calculi impacted in the Urethra.

MEDICAL SOCIETY OF LONDON.

Dystrophy of Thumb-joints.—Excision of Elbow-joint, and Tubercular Testis.—Tubercular Leprosy.—Pityriasis Circinata.—Congenital Constriction of Leg with Perforating Ulcer of Foot.

A CLINICAL meeting of this Society was held on Monday last, Dr. Wm. Ord, President, in the chair.

Dr. R. MAGUIRE showed a case of Dystrophy of the

Digitized by Google

Thumb-joints, in which inflammation of the carpo-metacarpal joints of both thumbs came on after the removal of two ovarian tumours in November, 1885. The arthritis has continued unabated, the veins about the joint are swollen, and there is increase of temperature; grating between the arthritic surfaces can be obtained. The thenar eminences are a little wasted, but there is no reaction of degeneration, only generally diminished reactions to both currents. Menstruation had ceased since the ovariotomy. Pain was the first symptom in the left thumb; the right followed later. The reflexes at the wrists were perhaps a little exaggerated. Absence of rheumatism, gout, and the relation in time to ovariotomy and the appearance of the disease when the joints were comparatively quiet, suggested a causal relation between the ovariotomy and the arthritis. It was connected not with congestion, but rather with anæmia of the genital regions. All treatment had proved of little avail.—Mr. WM. ADAMS did not think it could be placed amongst the neurotic alterations in joints. The principle of "rest and sweat" night and day should be employed in treatment.—Mr. B. JESSETT recommended complete rest of the joints.—Dr. WM. ORD believed that the case was one in which reflected "uterine" irritations were at work; the ovaries had been removed, but we did not know what the state of the uterus was.—Dr. MAGUIRE, in reply, said he presented the case simply as a clinical fact.

Mr. FRANCIS MASON exhibited a young man on whom he had performed Excision of the Left Elbow-joint, with good result in a freely movable joint. Since the operation a tubercular testis on the right side had developed, with infiltration in the right side of the prostate and the base of the bladder.—Mr. HURRY FENWICK, who showed this case in conjunction with Mr. Mason, suggested that the testicle became diseased as the result of infection from the joint, possibly about the time of the operation, and in consequence thereof.—Mr. STEPHEN PAGET did not perceive the reason why the testis should not have been produced under the same influences that gave rise to the tumor albus of the elbow-joint.

Dr. RADCLIFFE CROCKER exhibited a boy, aged sixteen, with Tubercular Leprosy, who had lived in Dominique, but was of Scotch parentage. There had been no privation; the boy had eaten fish. The leprosy appeared first in 1882, one year after the boy came to England to go to school. Febrile symptoms preceded the development of tubercles; the progress had been *saltatim;* febrile attacks accompanying each fresh crop of tubercles; the glands in the groin and elsewhere enlarged just before the febrile attacks. There were no definite tracts of anæsthesia; the ulnar nerves were not materially thickened; the mucous membranes of the tongue, epiglottis, and vocal cords were affected with tubercles; the nails had been destroyed in places; sometimes the tubercles ulcerated; and the typical bacilli had been detected. Gurjun oil had been employed with a little benefit.—Mr. SPENCER WATSON related a case.

Dr. RADCLIFFE CROCKER also showed a case of Pityriasis Circinata in a man aged twenty-seven. It began on the abdomen a month ago in oval or round patches, enlarging peripherally and disappearing centrally; at first bright red, becoming brownish and scaly. The disease generally ran its course in from one to two months. Vidal described a fungus microsporon, probably a micrococcus, but no real parasite had been discovered. Calamine lotion and liquor carbonis detergens were used locally.—Dr. STEPHEN MACKENZIE said that the micrococcus was an epiphenomenon, and might be found in any scaly débris from skin disease. The disease was not parasitic. Boracic acid was better than carbolic acid, though the latter relieved itching.—Dr. COLCOTT FOX said the eruption was more scanty in children, and occurred entirely on the trunk. It looked like psoriasis at first sight, but the distribution was different. A micrococcus was always present, but as an epiphenomenon.—Dr. R. CROCKER, in reply, said he considered the disease to be the same in children as in adults, between which there were all links.

Mr. J. H. MORGAN showed a case of Congenital Constriction by a Band producing Perforating Ulcer of the Foot, in a painter aged thirty-eight. On the right hand the fourth digit had no terminal phalanx and only a rudimentary second phalanx; the second and third digits were fused, and had only a proximal phalanx; there were no nails on these digits. The left hand index finger had a rudimentary second phalanx and no nail. The right lower limb showed a firm cicatricial contraction, which surrounded the knee below the patella; the leg was smaller on this side, and had a chronic sclerodermatous-like condition of the skin. There was a perforating ulcer on the under surface of the ball of the great toe, which tended to ameliorate. The knee-jerks were normal; some anæsthesia was present.—Mr. WM. ADAMS suggested that lymph bands in utero might give rise to the cicatricial markings in limbs by causing constriction. It was difficult, however, to understand the cases.—Mr. RITCHIE asked how much the malnutrition was due to vascular and how much to nervous damage.

Mr. SPENCER WATSON showed some New Instruments for use in the removal of Nasal Polypi.

OBSTETRICAL SOCIETY OF LONDON.

Removal of both Ovaries during Pregnancy.

THE annual meeting was held on Wednesday, Feb. 3rd, J. B. Potter, M.D., F.R.C.P., President, in the chair.

Mr. KNOWSLEY THORNTON read a paper on a case of Removal of both Ovaries during Pregnancy. M. W——, married, aged twenty-two, in the third month of pregnancy, was known to be large twelve months before marriage. She is now beyond the size of pregnancy, and has a large fluctuant tumour in the abdomen, which is growing fast. Has suffered from several attacks of pain in the abdomen, with rise of temperature, sickness, and faintness. Diagnosis: ovarian tumour complicated by pregnancy. Ovariotomy advised, and performed Feb. 4th, 1885. Dermoid tumours of both ovaries removed. Rapid and uninterrupted recovery. Premature delivery at eighth month. Labour uncomplicated. Lochia normal. Fine healthy child, and plenty of milk to nurse it. On examination, uterus found atrophic; patient, while nursing, suffering from flushes, chills, &c., just as others do who have an artificial menopause brought on by operation. The author made remarks on the interesting physiological and pathological problems which this unique case suggests.—Dr. JOHN WILLIAMS said that in a note read before the Society in 1884 he described the involution of the puerperal uterus in the absence of the ovaries. In that case the left ovary had been removed some years previously, and the right was removed soon after labour set in. The course of the process of involution might have been affected directly by the interference of the operation in his case; but in Mr. Thornton's it could not have been so, for the operation had been performed some months before labour set in. He would ask Mr. Thornton if any observations had been made on the process of involution in his case.—Dr. ROUTH remarked that the atrophy of the uterus could not impede lactation, and quoted Dr. Livingstone, who stated that the wives of the African kings were not allowed to suckle their own children, as it was thought derogatory. The child was given to the grandmother, generally an old woman, to whose mammæ and pudendum certain plants were applied and the child put to her breasts, with the result that she was able to suckle the child. He also alluded to well-authenticated cases in which men had suckled. He objected to the conclusion that menstruation always depended upon ovulation; this question hé considered undecided, and facts were accumulating to show that menstruation had really very little to do with ovulation. — Dr. MATTHEWS DUNCAN regarded tapping as the best treatment in cases of simple parovarian cyst. It involved less danger than extirpation, and was often successful. The extirpation of small papillomatous ovaries involved many difficulties. He did not believe any operation could cure where malignant disease had extended to several different parts of the peritoneum. He also reminded the Society that Dr. Tyler Smith had supported the view that the commencement of labour was a function of the ovaries. This view was now rendered almost untenable by Mr. Thornton's case. He had no doubt whatever that the ovaries were indissolubly connected with menstruation.

The following specimens were shown:—Dr. W. Griffith: (1) Uterus showing a Dilated Cavity; (2) Sarcoma of Uterus. Mr. Thornton: Papilloma of Ovary.

The Society then preceeded to the business of the annual meeting. The treasurer's report was adopted, on the motion of Dr. Playfair, seconded by Dr. Carter; the report of the hon. librarian, on the motion of Dr. Godson, seconded by Dr. Horrocks; the report of the chairman of the Midwifery Board, with a vote of thanks, on the motion of Dr. Matthews Duncan, seconded by Dr. Malins, and supported by Dr. Graily Hewitt. The scrutineers (Drs. Thomas and Lewers) declared the list of officers and council proposed by the

Digitized by Google

Council adopted. The President delivered the annual address, for which a vote of thanks was proposed by Dr. Graily Hewitt, seconded by Dr. West. A vote of thanks to the retiring officers (Dr. Herman and Mr. Thornton) was proposed by Dr. Gervis, seconded by Dr. Watt Black; and one to the retiring Vice-Presidents and other retiring members of Council was proposed by Dr. Routh, seconded by Dr. W. Duncan.

Reviews and Notices of Books.

Reference Handbook of the Medical Sciences. Vol. I. Aac-Cat. By various Writers. Illustrated by Chromo-lithographs and fine Wood Engravings. Edited by ALBERT H. BUCK, M.D. New York: Wm. Wood and Co.

THIS work, of which the first instalment is before us, which is to comprise eight volumes of about eight hundred pages each, will undoubtedly mark an era in the literary history of medicine and the allied sciences. It is quite impossible in the space at our disposal to give an adequate description of the merits of the production, whether we turn to the rare knowledge and skill which the several contributors have brought into requisition, or to the excellent arrangement of the subjects treated of, the type, and, last but not least, the admirable illustrations. Our readers will be able to form some idea of the completeness of the text and its illustration when we inform them that in the article "Applied Anatomy of the Arm" thirteen pages are devoted to the former and twenty-six woodcuts to the latter. How consistently and thoroughly the plan of the editor is carried out may be gleaned from a brief comparison of widely different subjects. Thus, almost immediately succeeding a classical dissertation on "Army Diseases" and "Army Hospitals" is a brief description of "Arnica," which includes the characters of the plant, its chemical and therapeutic properties, and other interesting details, to which is added an excellent chromo-lithograph. The pathological anatomy of disease is given in sufficient detail. Take, for example, the subject "Adenoma," the description of which is graced with four well-executed drawings.

The article "Blood" will earn for the author considerable repute. It contains a well-digested account of the salient features of that "fluid," both in its physiological and morbid conditions. It contains fifty diagrams, of which the greatest interest will attach to those representing the different instruments for estimating the number of corpuscles and the quantity of colouring matter in a given preparation; and the spectroscopical appearances, twenty-four in number, of blood under as many chemico-physical conditions. It remains to be said that each subject is fully up to the present state of knowledge and research. Attention may be called to "the running titles at the upper corners of the pages; these are intended to aid the reader in searching for a particular topic." A full index will be introduced at the end of the work. America is said to be the land of big things, and its title to the claim will not be belied by the Handbook now under review. We look forward with much interest to the production of the remaining seven volumes.

On the Supra-pubic Operation of Opening the Bladder for the Stone and for Tumours. By Sir HENRY THOMPSON, F.R.C.S., Surgeon Extraordinary to His Majesty the King of the Belgians, Consulting Surgeon to University College Hospital, late Professor of Surgery and Pathology to the Royal College of Surgeons of England, &c. London: J. and A. Churchill. 1886.

THE operation of supra-pubic lithotomy is undergoing a revival, as frequent notices in our pages during the last few years have sufficiently shown. It bids fair to supplant perineal lithotomy altogether; it is not without a pang of regret that older surgeons especially will part with an operation which has always possessed a special fascination, and the history of which is connected with many of the brightest names in surgery. The careful dissection through the abdominal wall on to the front of the distended and raised bladder bears but a very slight resemblance to the bold and rapid plunge into the viscus from the perineum, which in the hands of Fergusson and other brilliant lithotomists was the admiration of all spectators. The claim of the supra-pubic operation, however, is very strong, and the publication of Sir Henry Thompson's book will do much to impress its merits upon the minds of British surgeons, who have been slower to recognise them than their continental brethren. Two names will be associated with the revival of this operation—Garson and Petersen. To Dr. Garson of the Hunterian Museum belongs the credit of demonstrating the remarkable influence upon the bladder of full distension of the rectum, which so raises the viscus as to expose a considerable extent of its anterior surface bare of peritoneum above the pubes. To Petersen belongs the credit of availing himself of this anatomical demonstration and of supporting Dr. Garson's argument by clinical experience. All this, and very much more, of the history of the operation is told by Sir Henry Thompson, who gives a lucid description of the details of the procedure and the subsequent management of the patient, and appends notes of the cases in which he has himself practised the supra-pubic method. These cases include six instances of the removal of large stones, and two of the removal of large tumours. Dr. Tremaine of Buffalo has lately recorded three interesting cases in which he has successfully performed what he would have us call epicystotomy. In one case a stone measuring $2\frac{7}{8}$ in. by $1\frac{1}{4}$ in. was removed from a child three and a half years old; in the second case fragments weighing altogether over three ounces were removed from a man aged thirty; and in the third case from a man aged seventy-three a mulberry calculus measuring $1\frac{5}{8}$ in. by 1 in. was removed. In the last case the peritoneum was wounded, and the intestines protruded from the wound after the man was returned to bed. In the second case the wound in the bladder was sutured. In neither case was Petersen's distension of the rectum employed. Dr. Tremaine, like Sir Henry Thompson, found the fingers the most convenient means of extracting the calculi.

Acne: its Etiology, Pathology, and Treatment: a Practical Treatise based on the Study of 1500 Cases of Sebaceous Disease. By L. DUNCAN BULKLEY, A.M., M.D., Physician to the New York Skin and Cancer Hospital, &c. Pp. 280. London: J. and A. Churchill. 1885.

THIS well-got-up volume is in some respects a companion one to that on Eczema which has been favourably noticed in these columns. It is written in a similar practical way, is largely in accordance with views held in this country, and is characterised by careful details as to treatment, by a copious formulary, and a chapter on diet and hygiene. The pathological anatomy of the eruptions is minutely studied, and the beautiful illustrations of Dr. Bulkley's specimens form a striking feature of the work, and are especially valuable. We must also mention the addition of a very extensive bibliography, so that the volume is one which is very acceptable both to the worker at these diseases and to the practitioner. The author uses the term acne in its widest sense, and defines it as a functional or inflammatory disease of the sebaceous glands, exhibiting excessive and abnormal or deficient secretion of sebum; or the inflammatory elements of congestion, papules, pustules, or tubercles, located in and about the sebaceous glands, or in any or all of these features combined. The term therefore includes the diseases known as seborrhœa, comedo, and milium, sebaceous cysts, the ordinary inflammatory acne and rosacea, A. atrophica, and A. cachecticorum, Molluscum.

Digitized by Google

contagiosum is removed in accordance with recent pathological work from its time-honoured position as a sebaceous gland disease. In such a considerable volume we think the author might have rendered it still more useful by a more detailed exposition of certain points. For instance, there is only the barest discussion of that very interesting condition called stearrhœa nigricans, nor are there many references in the bibliography, because, we take it, some authors describe it as a sweat gland affection. The work is also far from being an exhaustive one, and in illustration of this we may mention the absence of any description of the peculiar follicular condition described by Cock, or of an explanation of the presence of sebaceous cysts on the palms. On one or two points we are inclined to criticise Dr. Bulkeley's descriptions—e.g., with regard to A. cornea, A. atrophica, and A. cachecticorum. Concerning the latter he follows Neumann, but does not tell us much of his own experience. We know but little of such an affection in this country. He describes A. cornea as a seborrhœa characterised by horny concretions in masses rarely exceeding half an inch in diameter; but this is surely not the disease described by Hardy. We think the description of A. atrophica decidedly poor, and we notice the author makes the old mistake between A. varioliforme or molluscum contagiosum and A. varioliformis. The latter, as we know it in this country, is rare, and is to be distinguished from deeply pitting acne in a scrofulous subject, and from relapsing acneform syphilides of the forehead and face. Its distribution, its remarkable pitting with the sunken scab, and its intractability to the ordinary acne remedies are characteristic.

OUR LIBRARY TABLE.

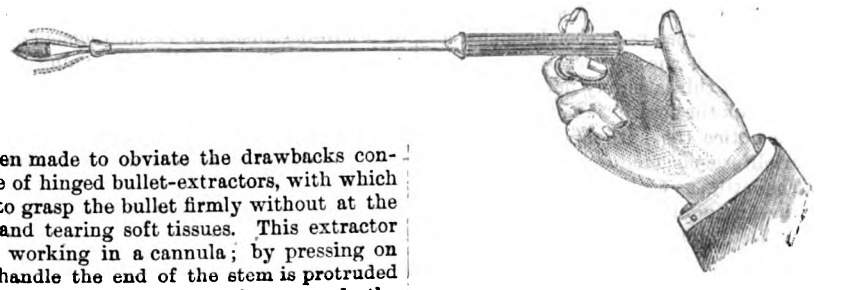
Report on an Outbreak of Enteric Fever in the Urban Sanitary District of Swansea. By EBENEZER DAVIES, Medical Officer of Health.—This outbreak, which occurred in the later part of last year, and which has since been carefully discussed in a report by the medical officer of health, has points of much interest. As many as 549 cases of enteric fever occurred, or 7·53 per 1000 of the inhabitants; and Mr. Davies was able early in his inquiry to eliminate milk-supply or defective drainage as a possible cause, and to show that the disease was confined to the drinkers of water from two reservoirs situated about eight miles from Swansea, the drinkers of water from local wells escaping illness. The conduits from the two mains are united about a mile from their commencement, and one common main conducts the water from both to Swansea. A detailed account is given of the opportunities for pollution of this water at one reservoir. The condition of one farm situated about 400 yards from the reservoir is mentioned as being one of indescribable filth, which would be easily washed into a tributary of the reservoir. Other surroundings were much of the same character, and the pollution of the town water with excremental filth was practically unavoidable. All that was wanted for the purpose of infection of Swansea was the admixture of enteric excreta with the ordinary filth of the neighbourhood, and this opportunity was abundantly afforded. The chief points of interest are, first, that chemical analysis of the water gave no evidence which would lead to its being regarded with suspicion, although it was analysed at a time when it was undoubtedly giving rise to disease; the second, that it became necessary to supply again to the town water from the infected reservoir after a short interval of time, and after much dilution, without the production of any extension of disease. The outbreak was well investigated; and it may be hoped that the local authorities of the district will adopt the recommendations embodied in the report.

The Journal of Anatomy and Physiology. Vol. 20, Part 1, 1885.—The Editors, Professors Humphry, Turner, and McKendrick, give notice that with this part the journal ceases to be issued by Messrs Macmillan and Co. and will be published by Messrs. Williams and Norgate. The chief articles in this part are: 1. A very good paper by C. B. Lockwood on a subject that might have been supposed to be worked out—viz., the Anatomy of the Muscles, Ligaments, and Fascia of the Orbit, including an account of the Capsule of Tenon, the Check Ligaments of the Recti, and of the Suspensory Ligaments of the Eye. 2. An article by H. St. John Brooks on two cases of Abnormal Coronary Artery of the Heart arising from the Pulmonary Artery, with some remarks upon the effect of this anomaly in producing Cirsoid Dilatation of the Vessels. 3. Mr. Ward Collins describes a Second Bursa connected with the insertion of the Biceps, and discusses some Rare Abnormalities. 4. Mr. Ernest Maylard gives some Abnormalities of the Lobes of the Human Lung. 5. Mr. J. Bland Sutton discusses the Nature of Ligaments. 6. Dr. Woodhead and Dr. Hare describe the Vital Relations of Micro-organisms to Tissue Elements. 7. Dr. J. Lockhart Gibson considers the Blood-forming Organs and Blood-formation. Dr. Noel Paton describes the Relationship of Urea Formation to Bile Secretion. 8. Professor Turner suggests the Index of the Pelvic Brim as a Basis of Classification. Lastly, the same anatomist gives the Anatomy of Sowerby's Whale.

The Quarterly Journal of Microscopical Science. Edited by Professors LANKESTER, DYER, KLEIN, MOSELEY, and SEDGWICK. New Series, No. 100. London: J. and A. Churchill.—From a notice issued with this part, we are glad to draw the conclusion that sound and careful microscopical research is on the increase, for the editors observe that the issue of supplementary numbers being found inconvenient, and an accumulation of valuable material remaining on hand, it has been decided to publish the journal henceforth at such intervals as may seem desirable rather than delay the appearance of the memoirs in question. The present number contains five articles and ten plates. 1. On the Chromatology of the Blood of some Invertebrata, by C. S. McMunn. 2. The Cephalic Appendages of the Gymnosomatous Pteropoda, by Dr. Paul Pelseneer. 3. Evidence in favour of the View that the Coxal Gland of Limulus and of other Arachnids is a Modified Nephridium, by G. Gulland. 4. Notes on the Embryology of Limulus, by J. S. Kingsley. 5. The Anatomy of the Madreporaria, by E. Herbert Fowler.

Jahresbericht über die Fortschritte der Pharmakotherapie. By Dr. KOBERT. Second Volume for 1884. Published by Karl Trübner. 1885.—This is an excellent compilation, and ought to prove of much service to the numerous workers in therapeutics and pharmacology. The information that it contains has been garnered from the most varied sources. There are references and abstracts on no less than 1867 subjects. There are indexes of authors as well as subjects. A glance through the book shows the remarkable character of much of the matter that it contains. We can fearlessly say that many of the names of the remedies herein treated of will sound very curiously to the ears of many medical men. Lippia mexicana is not a familiar remedy, but it appears to have been used with good effect in acute catarrh of the respiratory passages, as in other cases of cough and shortness of breath. It is a South American verbena which, according to Podwyssotski, contains an ethereal oil and a kind of camphor. Its nearest therapeutic ally is turpentine. This is the sort of information with which the volume abounds.

Orient Line Guide: Chapters for Travellers by Sea and by Land. Edited by W. LOFTIE, B.A. Pp. 309. London: Sampson Low and Co. 1885.—This is a second edition of a guide-book drawn up for the managers of the Orient Line of steamers with a view to give correct information as to the facilities



Digitized by Google

afforded by the company in the way of communication with our colonies, especially the Cape, Australia, and New Zealand. It contains much information, evidently collated with great care, which cannot fail to prove useful to intending travellers The advice given with regard to occupation, amusement, and attention to health during the voyage is judicious. The volume gives an account not merely of the various places to which the Company's steamers run, but also of those at which they call or which they pass *en route*, and of such places of note as can be easily reached from the different ports of call. It is illustrated with a considerable number of maps and charts, views of places that may be visited, and plans and portraits of the Company's ships. In addition to a copious index, a list is given of standard books on Australia, Egypt, and Italy. The names of the contributors to the volume, including G. Baden-Powell, Norman Lockyer, H. C. Middleton-Wake, and Mrs. H. Fawcett, are sufficient guarantee for the quality of the information afforded.

New Inventions.

A NEW BULLET-EXTRACTOR.

MESSRS. ARNOLD AND SONS, of West Smithfield, have patented a new bullet-extractor, which is here figured.

An attempt has been made to obviate the drawbacks connected with the use of hinged bullet-extractors, with which it may be difficult to grasp the bullet firmly without at the same time seizing and tearing soft tissues. This extractor consists of a stem working in a cannula; by pressing on the button at the handle the end of the stem is protruded and opens, and then, when the pressure is removed, the blades fall together as the stem is withdrawn into the cannula. By this means the bullet, when once grasped, is securely held during extraction, and the surrounding tissues are not liable to be seized or torn. Should the bullet be so firmly embedded in the tissues that the pressure of the soft parts equals the power of the spring to open the blades, the extractor is useless.

CULLEN AND CROFTS HOUSEHOLD DISINFECTOR.

WE have received a specimen of a convenient apparatus for the evaporation in a room of a disinfecting agent, such as thymol. The device consists of a bracket supporting a half-pint bottle, with a metal-covered cork, to which is attached a strip of cloth which lies immersed in the disinfectant, like the wick of a lamp. Means are provided for keeping the cork suspended over the mouth of the bottle as long as may be desired, leaving a portion of the saturated cloth exposed to the atmosphere. The apparatus is simple and inexpensive, and likely to be very useful. It may be obtained at the London Supply Company, 73, Ludgate-hill, E.C.

ON THE TREATMENT OF ANEURYSM WITH IODIDE OF POTASSIUM.

To the Editor of THE LANCET.

SIR,—In the last number of THE LANCET (Feb. 6th), Dr. Burney Yeo, in a paper on Clinical Therapeutics, remarks that "one of the most remarkable gains in the treatment of disease in recent years has been the employment of large doses of iodide of potassium in the treatment of internal aneurysms." With Dr. Yeo's permission, I wish to substitute "sufficient" for "large." Large doses are not necessary, and are sometimes injurious—at least if by large we mean doses over twenty grains. Nowadays, I believe, we have a perfectly trustworthy means of ascertaining when we are administering a dose which is sufficient. As soon as it was found to be probable that the iodide of potassium owed its curative virtues in aneurysm to its power of lowering the blood-tension, it also became evident that failures which were generally accompanied by an unduly quickened cardiac action were most likely dependent on too great a lowering of the blood-pressure; because this would not only account for the excited action of the heart, which had an unfavourable influence on the aneurysm, but would also permit the blood to flow away too rapidly to provide for the due nutrition of the tissues. But the cure of an aneurysm depends upon the hypertrophy of its coats, which cannot be effected without a certain amount of blood-pressure, neither can it occur if the blood-pressure remain at the normal, for all experience teaches us that the effect is then one of gradual though slow dilatation, with pressure corrosion of all the surrounding tissues. Hit the happy mean, and the effect is that the arterial coats behave like a hollow muscle, which hypertrophies when opposed to an obstacle with which it is able successfully to cope. To hit this happy mean and ascertain the proper dose, the patient is put to bed without any other treatment, and his pulse-rate ascertained night and morning for a few days. So soon as his average pulse-rate in recumbency is ascertained, he is put upon ten-grain doses of iodide of potassium every eight hours. If the pulse-rate remains unchanged the dose is increased to fifteen grains every eight hours, and every week an increase of five grains each dose is made till the pulse-rate begins to rise. In this way it has been ascertained that fifteen grains to a dose is seldom able to be exceeded, while it has often happened that ten grains has been found to be the most advantageous quantity. It is quite easy thus to find out what is a sufficient dose, and this has more than one advantage. With too small a dose we can do no good; with too large a one we do harm; we certainly delay the cure, and we may prevent it altogether. With a proper dose three months is generally sufficient to establish a marked improvement, instead of six months, the usual time before accurate dosage was resorted to. Now, also, we may say that the amount of relief obtainable from treatment in aneurysm is largely due to the period when the case comes under observation. If it is diagnosed early before there is much destruction of the arterial coats and surrounding structures, the cure is often practically complete. If the case is not seen till far advanced, then relief is all we can aspire to, but the relief to symptoms is often very great and remarkable, and it increases year by year. This doctrine as to the action of the iodide of potassium in aneurysm was carefully worked out clinically, and first enunciated in the *Edinburgh Medical Journal* for June, 1876, at p. 1142, and in the *British Medical Journal* for April 5th, 1879, at p. 511, forming part of the reported discussion as to the treatment of internal aneurysms at a meeting of the Glasgow Pathological and Clinical Society on March 5th, 1879, and it will also be found *in extenso* at pp. 453-463 of the second edition of my work on Diseases of the Heart, 1882. I mention these facts, as I have noted in various papers and published works an amount of ignorance on the subject not creditable to the research of the authors.

I am, Sir, yours sincerely,

Edinburgh, Feb. 9th, 1886. GEORGE W. BALFOUR.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 20, 1886.

DR. OGLE'S communication to the Statistical Society of London on the subject of suicide is one of great interest and considerable value. The manner in which he has treated the matter shows the skill and, which is equally essential, the caution of an intelligent expert in statistics. There are statisticians of high attainments in the art of collating returns who are not intelligent. The story which Dr. OGLE had to tell is sufficiently lugubrious. During the twenty-six years 1858–83 no fewer than 42,630 persons appear on the records as having died by suicide in England and Wales. The actual number is doubtless greater than this, as the returns "found dead" are not included. As regards age, during the period named only two children under ten have died by their own hands, but from fifteen to sixty-five years of age suicides increase rapidly. The greatest proportional rise occurs between twenty-five and thirty-five, when the majority of men and women come to face life in its reality, and find how hard and cruel it is. After sixty-five, as we should expect, the rate falls. Sex affects the question. Thus, setting aside age for the moment, the rate per 1,000,000 is 104 for men, while it is only 41 for women. Looking to the age-distribution in the adjustment of proportion in relation to sex, Dr. OGLE gives the suicides among males as against suicides among females as 267 to 100. Men have to bear the brunt and worry of life, and upon them chiefly falls that trouble of mind which is the main cause of self-murder. Occupation plays a part in the issue. Soldiers stand first on the list. Inn and hotel servants come next; then innkeepers, publicans, spirit, wine, and beer dealers. Medical practitioners follow close upon the publicans, the figures being almost identical; and chemists and druggists come a very short way behind. Barristers and solicitors are not greatly less prone to commit suicide. Butchers, fishmongers, poulterers, greengrocers, and fruiterers are about on a level with barristers in regard to the probabilities of death by self-murder. The occupation least predisposing to suicide, if it were permissible to look at the matter in this way, would seem to be that of a miner, perhaps because the risks to life in that calling are sufficiently numerous without importing extraneous modes of death by violence. Shipwrights and shipbuilders are the next contented class. Next above the last stand clergymen, priests, and ministers, though considerably above; thus, while the suicides among miners are only 74 per 1,000,000 living, and those among shipwrights are 96, the clergymen &c. number 139. The enormously high proportion of suicides among soldiers, 1149 per 1,000,000 living, while the proportion for "all males" is only 222 per 1,000,000, is very remarkable. Dr. OGLE has, as we have said, been careful to take age-distribution into account when dealing with the question of occupations, but we are not so sure that he has given full effect to the trade-distribution. He says, "To compare the suicide-rates of such contrasted occupations as these, without any regard to the difference of age-distribution, would clearly be absurd," and he has taken means to avoid the risk of error in this respect; but has he also guarded against the error of ignoring the distribution of occupations? For example, if a particular calling is one which bears a large proportion as regards the number of persons engaged therein to the numbers of persons engaged in other trades respectively, it is manifest that any general rate must be localised in the particular class proportionately; and the rates of the several classes will compare well with each other and with the total of living persons in due relation. We need a table showing the proportions of the total population engaged in different occupations to test the value of the occupation-tables in Dr. OGLE's computations. Doubtless the author had such a table at hand, and probably he used it, but the reader might with advantage have one also. The importance of the point raised may be stated thus: If the persons occupied as soldiers numbered, say, 60,000, and the medical practitioners were 20,000, obviously the same rate as regards the general population would produce three times as many soldiers among the suicides as among the doctors. So with all the other occupations. The proportion of suicides in each occupation must obviously bear a constant relation to the relative number of persons engaged in it, and it is only the *excess* or *deficiency* which would characterise the occupation as a cause or preventive of suicide. We want to know more than Dr. OGLE tells us on this point before we can draw practical deductions. The bearing of the statistics furnished on seasons is very noticeable. The greater number of suicides occur in May and June, slightly more in the latter month. The author states the belief, although he does not endorse it, that the heat of the weather may tend to induce insanity; but surely it is nearly as hot in July as in June, and hotter than in May, and yet the suicides in July fall considerably, while in August they are less again. The truth is that in May and June the worries arising out of the financial disasters of the preceding year culminate in law proceedings, and the embarrassed are brought face to face with the final issue of their difficulties. Then they succumb. In December the number of suicides is scarcely more than half as great as in June. Dr. OGLE remarks: "Possibly the explanation may simply be that as the days grow longer the movement of life, be it for business or for pleasure, becomes more and more active; and that the changes in the amount of suicide correspond to the consequent changes in the amount of mental excitement." November, which used to be popularly considered the month of suicides, is among the least prolific; only December and February are below it. We cannot help thinking that the relation is closer with periods of greatest anxiety with respect to money matters than to weather or other circumstances of existence. As regards methods of suicide, hanging is the most common; drowning and throat-cutting or stabbing come next in order, then poisoning, gunshot, jumping from a height, and last by railway train. Men, as a rule, hang themselves or cut their throats. Women generally commit self-murder by drowning or hanging; in a lower proportion they take poison. If men use poison for the purpose of suicide, it is most frequently prussic acid, oil of almonds, or cyanides, and next laudanum. Women choose laudanum or employ a

Digitized by Google

vermin-killer, probably because the latter falls easily in their way. Speaking generally, a man resorts to some means within his reach or suggested by his occupation. Thus, chemists and druggists, medical practitioners, and photographers poison themselves; soldiers use firearms; butchers cut or stab, though they slightly prefer hanging, and so on. Clergymen, lawyers, and independent gentlemen use firearms; but all classes exhibit a tendency to resort to the rope, doubtless because it is considered the easiest mode of death, and because the appliances are always at hand. One curious fact in connexion with the choice of method Dr. OGLE states briefly thus: "If the year be divided into two periods of six months each, the one from October to March, the other from April to September, inclusively, out of 1000 suicides committed in each period there are in London, on an average of twenty years, 205 suicides by drowning in the warmer period, and only 177 in the colder period. This is only another example of the fact which came out more strongly when the choice of poisons was under review—namely, that even when about to commit suicide, persons are not indifferent to considerations of comfort or discomfort. The idea of death in cold water appears repulsive in winter seasons, and that method of self-destruction is avoided."

The paper, as a whole, is replete with materials for a statistical study of the subject of suicide, and will do good service by throwing light on a question of painful but urgently grave interest. "The total chance of dying by suicide," as Dr. OGLE calculates it, "is much more considerable than would probably be supposed by anyone who had not examined the question: few, for instance, would imagine that one out of every 119 young men who reach the age of twenty dies ultimately by his own hand. Yet such is the case." In face of figures so startling as these, it cannot be gainsaid that the subject of suicide is appalling in its magnitude. We must defer the mention of considerations arising out of the psychology of the question which Dr. OGLE rather suggests than undertakes to discuss. The Society before which his paper was read being purely statistical, the author properly restricts his view to that aspect of the topic; but there are others in respect to the study of which his excellent compilation will greatly help us.

IN the minutes of the meeting of the Council of the College of Surgeons, which we published last week, there is no word of allusion to what we may call the differences at present subsisting between the Council and the Fellows and Members at large. On the other hand, the Council seem to be pushing on with their own schemes. Authority was given to the Building Committee to make the necessary arrangements for the ceremony of laying the foundation stone of the new Examination Hall, which it has been decided to build in conjunction with the College of Physicians. Meanwhile, Mr. HUTCHINSON'S motion concerning the Fellowship has not yet been reported upon, although two months have elapsed since the committee for that purpose was appointed. Outside the Council, however, there are evidences of activity that can hardly fail to lead to results. The Association of Members has now in circulation for signature a petition to the Queen in Council, praying that no alterations be granted in the present Charters unless the same provide for the due representation of the Members on the Council of the College, and the exercise of other privileges which pertain to membership of a corporate body. This is reasonable enough. But something more is required of the Association than this. It must show itself to consist of practical politicians, and to this end must definitely draw up and publish a confession of political faith. On what grounds are they ready to treat with the present Council? On what grounds are they ready to join the Association of Fellows? Although for the purposes of the last public meeting some agreement was arrived at by the two Associations, or rather by their delegates, we are not aware that the Association itself has definitely agreed upon the nature of the suffrage they are seeking. Now, it is most important, in order to secure the co-operation of the Fellows and of the best and oldest of the Members, that an authoritative statement should be made to serve as a basis of action. In other words, a complete draft scheme of reform should be drawn up, the assistance of some experienced Fellows of the College, and even legal assistance, being secured in order to make it thoroughly reliable and workable.

Of first importance is the decision of the necessary standing as Member to secure a vote, and for eligibility to sit on the Council. Next, in what proportion to the Fellows *may* Members be chosen. It must be decided whether Members *may* or *shall* sit on the Council, or whether it shall be optional with the constituents to elect councillors irrespective of title. Of hardly less importance will be the method of voting, the formation and maintenance of a register, the amount of fee (if any) to be paid, whether Members resident beyond the United Kingdom shall be eligible for registration, and a variety of other questions of a like kind. A draft scheme of some kind ought certainly to be ready when the proper official, through whom the petition would be taken to the QUEEN, is approached for this purpose. We can hardly doubt that if a scheme of reform could be drafted on liberal yet moderate lines, keeping the academical and the political status quite distinct, and free from any personal element, there would be a large access of support which at present holds aloof on account of the uncertainty of the aims and objects of the present reform movement. Further than this, which, however, is a necessary preliminary step, the Association of Members should seek alliance or amalgamation with the Association of Fellows. Such a union would give a strength and moral weight to each of the Associations which neither can exercise alone. The Members especially would gain, for they have only just awakened to their position; while among the Fellows there are some who have given thought and study to the matter for a good many years past. The Association of Members would do well to endeavour to secure the help and assistance of one or two of the more active members of the Fellows' Association in drafting their reform scheme. There are two gentlemen who are, before all others, conversant with the history and Charters of the College, and it has been largely through their initiative and practical common-sense that so much progress has latterly been made. Nor should the Association lose any time in securing the patronage and help of the medical members of Parliament.

In his letter, published last week, Mr. TWEEDY suggests several points which the promoters of the new Charters must steer clear of, one of the chief being "exclusiveness." The present Council, he shows, "is a much less representative body than is commonly supposed"; for, though avowedly elected by the voice of the 1100 Fellows, each individual member is really the nominee of some six-score private friends. Mr. TWEEDY further points out that, owing to the restrictions enforced by the Charter, the area of selection is reduced to a few old or middle-aged surgeons connected with the London hospitals. This exclusiveness has probably never struck the majority of our readers in its full sense; it is probable that the members of Council themselves hardly realise how little they represent the Fellows even, and how completely out of touch they are with the great body of the Members of the College.

In urging the Members to join hands and push forward, we must nevertheless counsel moderation. Their strongest argument in favour of obtaining the rights which have so long been denied will be a business-like conduct of their present campaign; and no better proof of fitness to exercise these rights can be given than the moderation they use in winning them.

IN selecting as the subject for his Lettsomian Lectures 'Some Moot Points in the Natural History of Syphilis" Mr. JONATHAN HUTCHINSON made a very wise choice. Syphilis is a disease which is always present amongst us. It comes in some form or another before the notice of every medical practitioner, whether specialist or general. It is also a disease which, though most amenable to treatment when diagnosed at its onset and promptly treated, is the immediate cause of death to a large number of infants, and the primary cause to a very large number of adults every year. Its early diagnosis and prompt treatment are therefore matters of paramount importance, and Mr. HUTCHINSON is to be congratulated not only in his choice of a subject, but also on the able manner in which he has handled it. The literature of syphilography is quite as marvellous as that of any other department of medicine or surgery. Practitioners are living who can remember the days when gonorrhœa was treated with mercury, even to profuse salivation, on the principle that it and syphilis arose from a common poison, for which mercury was the sole cure. To a very large extent syphilis was till a comparatively recent period ostracised from medical societies and medical literature, much in the same way that syphilitic patients of the lower orders are still ostracised from our general hospitals and relegated to a few lock hospitals and wards or to the out-patients' departments. The treatment of venereal diseases was viewed askance by legitimate practitioners, and a reputation for their treatment was rarely sought, this being left to quacks and chemists—a condition of things which still lingers amongst us, though happily to a greatly reduced extent. To these and other causes, but principally the former, is to be attributed the fact that the average general practitioner is more or less imperfectly acquainted with syphilis, and that even among specialists in venereal diseases there should be these "moot points" still remaining to be decided. Hence also arises the circumstance alluded to by Mr. HUTCHINSON: how comparatively young is almost all our knowledge as to the transmission of syphilis from parent to child. The various works published in this country on the subject of syphilis have seldom gone beyond a second edition, while many have not even reached this. In his many writings on this disease, and more especially in his article on Constitutional Syphilis in "Reynolds's System of Medicine," Mr. HUTCHINSON has treated the subject with a vigour and freshness which make it much pleasanter reading than previous writers have succeeded in making it, and the recent Lettsomian lectures are no exception to this rule. All the various questions of unity or duality, phagedæna, recurring chancres, syphilis after vaccination, the relationship of tertiary to secondary symptoms, nerve affections, the position of rupia and psoriasis palmaris, mercurial treatment, recurrence of syphilis after long treatment, and, last and most important of all, the question of hereditary syphilis,—these are all discussed with an ability which must commend them to the attention of all who peruse them.

But while wishing to do ample justice to the ability with which Mr. HUTCHINSON has treated a difficult subject, it must be admitted that some of his conclusions are at variance with those of other writers whose experience and ability cannot be questioned. Mr. HUTCHINSON is not free from the error into which so many writers on syphilis have fallen—namely, that of being too positive. Thus, in his first lecture it is clear that he regards all venereal sores as related to syphilis and not independent. "If a person who has never suffered before contracts a venereal sore of any kind, it is highly probable that it will lead to syphilis." Mr. HUTCHINSON adds, in confirmation of this, the statement of Mr. MORGAN, of Dublin, that of fifty-four patients with first attacks of venereal sores, fifty were proved to have true syphilis. It would be very interesting to have some additional details as to these cases. Was the period of incubation short or long? Was induration present? Were the inguinal glands affected? Are we to assume that because they are termed venereal sores, all these indications were absent? Considering how many men suffer from a chronic excoriation of the inner prepuce, and the filthy state of the vagina in many prostitutes, there seems nothing improbable in the belief that sores may arise which will be long in healing, and may yet be perfectly independent of syphilis. Then as to phagedæna. Mr. HUTCHINSON'S views are not confirmed by the experience of Mr. JAMES LANE, Mr. BERKELEY HILL, and other hospital surgeons; nor is it proved that phagedæna is more prevalent in lock than in surgical wards. In his second lecture, Mr. HUTCHINSON makes a somewhat remarkable contradiction. He says that if a small dose of grey powder be given to a patient with an indurated sore, but in whom as yet no secondary symptoms have appeared, the result will usually be that none will appear; but further on he says that if at the end of a six months' course the remedy be stopped, an outbreak of symptoms will occur within a few weeks of its suspension, and that this usually takes the form of an erythematous or lichenoid eruption. There are many other points to be noted which can scarcely be comprised within the limits of one article. Enough has been said to show that the "moot points" must remain such till more and varied experience

Digitized by Google

has been brought to bear upon them. Hence the importance of carefully noting all the varieties of diagnosis, prognosis, and treatment in every case of syphilis which comes to the notice of the general practitioner or specialist.

DR. AUSTIN FLINT may be called the WATSON of the United States. A very admirable specimen of his writing and thinking as a practical physician is a paper read by him before the New York County Medical Association on November 16th, and contained in the *Journal of the American Medical Association* for January 9th, and entitled Elements of Prognosis in Bright's Disease. The general purport of the paper is to encourage a more hopeful, or, at any rate, a less gloomy view of the disease than is commonly entertained either by the public or the profession. His main conclusions may be thus summarised. Acute Bright's disease, as a rule, does not tend to a fatal result. A subacute diffuse nephritis occurs not only after scarlet fever and other infectious maladies, but irrespective of these, and is liable to be mistaken for chronic morbus Brightii. It can only be distinguished by the disappearance of all signs of renal disease after some weeks and the recovery of health. As regards prognosis in chronic Bright's disease, Dr. FLINT considers its frequent latency to be a very important clinical fact—that is, there may be no important symptoms apart from the result of an examination of the urine. For this to be the case three conditions must obtain: first, the kidneys must not be damaged beyond a certain extent; secondly, the important organs of the body other than the kidneys must be fairly healthy and efficient; thirdly, the laws of health relating to alimentation, exercise, exposure to cold, mental excitement, and habits of life must be observed. Given these conditions, he thinks there might be a lesion of the kidneys, diminishing their functional ability to one-half, but not in its nature progressive, which would be compatible with the indefinite continuance of life and health. Dr. FLINT is brought to this conclusion, not only by his experience as a physician, but by the recent demonstrations by surgeons that nature has endowed us with twice as much renal tissue as we absolutely need for purposes of life. Dr. FLINT insists on the importance of a careful examination of the urine, not only as to the presence of albumen and casts, but as to the quantity of urine and its specific gravity. The liability to grave uræmia depends not only on the state of the urine, but on other accessory facts, of which two are important—the chance of vicarious elimination by other organs, and the comparative insensibility of some persons to the toxical effects of uræmia. In cases of uræmic coma or acute œdema of the lungs the prognosis is of course grave, but Dr. FLINT even here is not hopeless, and has seen cases of recovery. His suggestion is that the attacks are due to an intercurrent, acute or subacute, nephritis, which under proper care and treatment passes off. Of one complication, "renal asthma," or dyspnœa without pulmonary affection, on the other hand, Dr. FLINT speaks with no hope. He regards it as probably due to a toxical effect on the respiratory centre in the nervous system. We give prominence to this paper, not only for its own sake, but as a good specimen of the quality of looking for the best side of bad facts, which is one eminently for cultivation by medical men, and which has been rather discouraged since pathological processes engaged so much the study of physicians, apart from the time they have occupied, and the circumstances favouring or retarding them. Dr. FLINT is not alone in this estimate. We once asked Dr. JOHNSON how long he had known a case of albuminuria to extend? He replied thirty years. We may safely conclude that a disease which could be extended over thirty years might with more care extend over forty, and leave life very much uncurtailed. But this implies great care on the part of the patient and physician alike.

LAST Saturday the Metropolitan Asylums Board resolved, on the recommendation of their General Purposes Committee, to erect at Gore Farm a hospital for the accommodation of 600 persons suffering from small-pox. Sir EDMUND HAY CURRIE, in bringing up the report, described the amount of hospital provision which would then be available at the time when small-pox next assumes epidemic prevalence in the metropolis. The Committee estimated that the five London hospitals would provide 40 beds each, or 200, the hospital ships another 300, making, with the proposed hospitals, 1100 beds for cases of small-pox. We fully sympathise with the desire of the Managers not to delay the steps which must be taken to meet the exigencies of the next epidemic, but we see with a feeling akin to dismay the complete absence of any appreciation of the need for a thorough reconsideration of the whole subject of hospital provision for small-pox. The Managers adopted a resolution which contains an expression of satisfaction at the "success which has attended the new departure in the treatment of small-pox cases in accordance with the recommendations of the Royal Commission." There has not been wanting evidence that this departure, as interpreted by the Managers, is attended by serious consequences.

The hospitals at Fulham and Hampstead have been definitely shown to be a fertile cause of disease to the neighbourhood in which they are placed. The evidence against the other hospitals is considerable, yet the word "success" is associated with the system that includes their use. For some time a controversy has been going on between the Local Government Board on the one hand and the Metropolitan Asylums Board on the other as to the continued use of the land hospitals or the ships on the river, and the latter Board, probably influenced by the unfortunate results which have attended the use of the land hospitals, have persistently declined to close the ships. This is a matter upon which the lives of a number of people are dependent, and it might be expected that in view of such serious issues both Boards had exercised all their powers to learn whether the misfortunes which have befallen the residents near to the land hospitals have been shared by those who live in the neighbourhood of the ships. So far as any information is available, there is reason to believe that the Local Government Board have made inquiry as to the influence of one hospital, that at Fulham; while the Metropolitan Asylums Board have taken no step to obtain any knowledge whatever of the results of their procedure, and this is all.

We cannot but regret the decision of the Metropolitan Asylums Board to embark in fresh and large expenditure until the best method of the construction of small-pox

Digitized by Google

hospitals has been fully determined. The proposed institution is probably intended for convalescents, and Mr. POWER'S observations have led us to hope that hospitals containing patients in this stage of disease are not capable of disseminating infection to the same extent as those containing persons in the early stages of small-pox. But in practice we anticipate that the Managers will remove from London all persons suffering from small-pox who can bear the journey, and if this course be adopted the institution will in its use be similar to those institutions which have become known to be a source of danger to the neighbourhood in which they are placed. Last week we pointed out that only a portion of the recommendation of the Royal Commission had been adopted, and we recur to this for the reason that any further large expenditure ought only to follow the fullest investigation of the effects of aggregation of severe mild, and convalescent cases of small-pox.

Annotations.

"Ne quid nimis."

THE EXEMPTION OF PUBLIC CHARITIES FROM RATES.

WE have already expressed a strong opinion on the unreasonableness of assessing hospitals and other charities for the payment of poor rates and other local rates. A powerful statement has been drawn up by direction of the executive committee of the "Charities Rating Exemption Society" for the consideration of members of the Legislature, which we commend to every member of Parliament and to all who can influence members of Parliament. According to this statement, it has been a principle of the Common Law in Great Britain for two centuries and a half to exempt public charities from liability to public rates. This principle has been applied to many kinds of institutions, but its most obvious application is to hospitals supported by voluntary contributions, which are so essentially benevolent in function, and which so obviously relieve not only the poor who cannot pay rates, but the ratepayers and taxpayers themselves, who would otherwise have to support these institutions. The Irish Poor Law Act (1838) recognised the principle. Under the 32 and 33 Vict., cap. 40, Sunday and Ragged Schools were exempt from rating. The Town Improvement Act of 1847, consolidating the various Acts for lighting, paving, and improving towns, exempted buildings devoted to public worship, to gratuitous education of the poor, and to public charity. Such buildings were exempted from even the Income Tax, and from that still more stringent tax, the Land Tax of 1797. Many local Acts contain provisions for the exemption of charities. But law is sometimes very accidental and unsatisfactory in its deliverances, and by a most curious and, to laymen, unintelligible accident, a decision of the judges referring to the liability of the trustees of the Mersey Docks and Harbour Board to be rated to the poor was wrested to apply to charities; and now some charities are rated and others are not. Some hospitals are heavily rated. No Parliamentary authority for their being rated exists, but we presume they pay on the view that it is cheaper to pay than to contest their right to exemption. We can only repeat a strong expression of the injustice and impolicy of subjecting to rates hospitals whose very operation is to keep the poor off the rates. It is perhaps too much to hope for the present, when legislation seems reduced to a mere battle of parties, for party purposes, to gain attention to the claims of institutions which transcend all party considerations. But better days may be at hand, and when they come we cannot doubt that our legislators will exempt genuine charities for the future, as they have been exempted in the past centuries. The paper of Mr. Wood at the Hospitals Association, and the discussion which followed, will do much to place this subject well before the public mind and that of Parliament. It is impossible that the question can remain as it is. Some hospitals are rated and others are not. Some are assessed at a very high rate, others at a very low one. Thus, according to a very interesting table drawn up by Mr. Wood, Guy's Hospital pays for rates and taxes £1400, St. Thomas's £2133, the London Hospital £56, and St. Bartholomew's nothing at all! While certain charities are exempted from rating by specific Acts of exemption, the greatest of all pure charities—the hospitals—remain for the random attacks of overseers. Where these officials are tender-hearted, the hospitals go scot free, or are taxed so lightly that their trustees feel half disposed to let things alone; where the officers are astute, hospitals are heavily rated, as if they were a source of profit to their supporters, and not a great means of lightening the burden of the ratepayers.

UNCONSCIOUS IMPREGNATION.

AT the recent Manchester assizes a man named Jackson, a dentist, was sued for damages for the alleged seduction and consequent pregnancy of a young woman aged twenty-five. The facts, as stated in evidence, were so remarkable that it is not surprising the jury were discharged without giving a verdict. The case is interesting from a medico-legal point of view, and shows the danger of administering anæsthetics in the absence of a third person. It appears that the woman went to Jackson for the purpose of having a tooth extracted, and whilst under the influence of gas the defendant, according to the allegation set forth in the statement of claim, ravished her. The plaintiff at the time was engaged to be married, and it does not seem that she made a complaint to her intended husband of the supposed assault—in fact, she even allowed the banns of marriage to be published, though cognisant that she was *enceinte*. Two questions arise in connexion with the case of the highest import. Is it possible for intercourse with a virgin to take place during the short period of insensibility and semi-consciousness following the administration of nitrous oxide gas? We take it that, although possible, it is in the highest degree improbable. But there can be no doubt that, granted the accomplishment of the act, the answer to the query, "Can unconscious impregnation happen under such conditions?" must be in the affirmative. Cases are on record in which women have conceived during sleep and the state of anæsthesia induced by gas is only another form of sleep. If we are correctly informed of the facts, we cannot understand why the plaintiff proceeded against the defendant by civil process and not by criminal indictment, for if the story of the woman is true, surely the man was guilty of felony. Perhaps the fact that the plaintiff did not make immediate complaint of the alleged assault weighed heavily in the balance on the side of the accused. Such a charge as the one above referred to is difficult and may be impossible to refute, and consequently it is only just that the strongest corroborative evidence should be required to justify a conviction or a verdict for damages, or, failing that, there should be a complete investigation of all the collateral circumstances as regards the conduct of both parties *re* the charge, and also a searching inquiry into their general credit. From an impartial survey of the medico-legal and moral bearings of the case as reported in the *Manchester Guardian*, we cannot help expressing the opinion that upon the evidence before them the jury could scarcely have found for the plaintiff.

VACCINATION ARRANGEMENTS IN PENNSYLVANIA.

THE State Board of Health of Pennsylvania have issued a series of circulars relating to such matters as the precautions to be taken against cholera, the sanitary supervision of travel and traffic, and the precautions to be taken against small-pox. Adverting to the deplorable anti-vaccination agitation in Canada, the latter circular expresses the conviction that the public in the State are generally too well informed and intelligent to take part in any ignorant attempt to thwart the beneficent efforts of the health authorities to check the spread of disease, and they urge the vaccination of all infants within three months of birth, the revaccination of adults, and the adoption by all public School Boards and trustees of a rule requiring that every child entering school shall give satisfactory evidence of having been vaccinated. In this way indirect compulsion would be brought about, but they admit that, in order to give effect to it, the establishment of vaccination stations somewhat on the lines adopted in this country will have to be carried out; and having a desire to give the inhabitants the opportunity of getting lymph direct from the calf, the State Board of Health have decided to encourage the establishment in the immediate vicinity of the cities of Philadelphia and Pittsburg of vaccine farms, under the supervision of skilled physicians, where every provision will be made for ensuring the health of the animals used for the purpose of propagating the lymph, with the most scrupulous cleanliness of their surroundings. From these establishments it is proposed to issue lymph to meet every emergency, and this at the lowest possible price.

THE ARMY CLOTHING DEPOT.

ONCE more an agitation has arisen with respect to the management of the Army Clothing Depôt at Pimlico. It may be remembered that in February, 1878, we published a special report on the contamination of the uniforms provided to the British army. We then proved, firstly, that many persons who attended at the Pimlico factory lived in fever dens, which had not been detected by the authorities and, secondly, that those who were allowed to take their work home sometimes made the uniforms in overcrowded rooms, and by the side of small-pox or scarlet fever cases. The publication of these facts caused so great a sensation that a special inquiry was instituted by Government. Measures were taken to reduce the amount of out-door work, but their principal feature consisted of a reduction of wages. By this means it was argued that the Government factory would be better able to compete with private contractors, who were the greater offenders. But, considering that the ideal wages only equalled an average of 15*s.* or 16*s.* per week, there was not any margin for reduction, if the workers are to be fed and lodged properly. Nevertheless, as time wears on, the policy of management seems still to incline towards lower and lower wages. Great-coats, when made within the Government factory, are paid for at the rate of 2*s.* 2*d.* each for the work expended thereon. When given to workers outside only 1*s.* 10*d.* is allowed, and workers have to find their own material, &c., which is equal to a further reduction of 4*d.* Hence the outside tailoress only nets 1*s.* 6*d.* instead of 2*s.* 2*d.* on each great-coat. This is not the way to promote public health; and how can it be expected that poor women, when thus underpaid, should voluntarily declare the presence of infectious diseases in their midst? Such a declaration would deprive them of their work, and this without compensation. On the other hand, as the work is so badly paid, they cannot be expected to save sufficient to submit willingly to an expensive isolation or quarantine. If it is not our province to discuss the wages question, it is certainly our duty to insist that a liberal allowance should be made to all those who frankly confess that they cannot work because an infectious disease has broken out in their homes. No law at present exists to compel private contractors to make such allowance to their work-people; but the Government may be called upon to set the example, and to give out work only to those employers who follow this initiative. Isolation and disinfection are indispensable, but the one and the other will always be avoided, whenever possible, by those who work on the verge of starvation, unless they are liberally compensated for the loss of employment involved by the enforcement of these sanitary measures.

A READY MEANS OF PRESERVING THE FLUIDITY OF BLOOD.

A STUDENT in Professor Stricker's laboratory, Herr Ernest Freund, has, it seems, suggested a most simple and convenient method of preserving blood in the fluid state. His plan consists in coating the interior of a glass vessel with pure oil. Into this receptable blood freshly drawn is poured, and a layer of oil is then run over the surface exposed to the air. In this way, we are assured, fresh blood may be kept from coagulating for days if necessary. It is difficult to see how so simple an experiment, if once satisfactorily demonstrated, should afterwards be discredited by repetition. We may therefore hope that this apparently trivial application of a physical law will be a real gain to practice as well as research. In particular it should obviously facilitate the operation of transfusion, though it will not entirely replace that still more ready means of treatment, salt solution. It need hardly be said that this mode of preventing coagulation is new rather in its easy and general application than as illustrating a principle for the first time discovered. Professor Ludwig made use of the same idea in estimating the velocity of the blood-current.

PRINCE TORLONIA.

ITALY has lost a great benefactor in Don Alessandro Torlonia. His colossal wealth, amassed in successful banking speculation, was freely spent in the encouragement of art, in the prosecution of public works, in the founding and maintenance of hospitals, and in the relief of the poor. One has only to visit the churches, the basilicas, the palaces, the theatres, and the villas of Rome to see how much of their recent ornamentation is due to his employment of architects, sculptors, and painters, whom his judicious patronage has raised to distinction. The drainage of the Lago di Fucino—an undertaking which had baffled even the Emperors Claudius and Hadrian, with their command of engineering talent and of unlimited slave labour—has restored it to its proper dimensions, reclaimed the arable soil it inundated, and minimised the palustral exhalation that kept the husbandman aloof from its margin. For the completion of this work, which will rank with the Mont Cenis and St. Gothard Tunnels and the Suez Canal as a notable achievement of the century, King Victor Emanuel created its promoter Prince of Fucino, and in honour of the event had a gold medal struck, which the Torlonia family will justly cherish among its title-deeds to nobility. The hospital for the orphan and the superannuated erected and maintained by the Prince at S. Onofrio, the infant asylum and professional school for the upbringing and training of three hundred children of both sexes, and in immediate connexion with this the famous "Ambulatorio chirurgico" organised under the great surgeon Costanzo Mazzoni, are all monuments of the large-hearted and free-handed "Don Alessandro," as the Romans loved to call their unwearied benefactor. Making no pretensions to patrician lineage, the banker-prince represented

Digitized by Google

far more effectively than the average Italian noble that paternal care for his inferiors and dependants which was one of the redeeming attributes of the feudal system. Though loyal to the Vatican, he frankly acknowledged Victor Emanuel as King of United Italy, and when Garibaldi came to Rome eleven years ago with his plan for deflecting the Tiber, reclaiming the Campagna, and reviving the port of Fiumicino, Don Alessandro gave him a courteous and kindly reception, and sent him away with the conviction that, had the plan been feasible, the money would be forthcoming till its completion. In these days, when the sharp contrast between rich and poor is driving wilder spirits to the "Tartarus incline" of revolution, such wise and wide benevolence as that of Prince Torlonia will have its restraining effect, and reconcile the toiling masses to a social inequality under which there is always opportunity to rise and to crown a successful career with its happiest privilege—"the sweet task of providing."

CAN A HERNIA DISAPPEAR IN A FEW WEEKS?

A SAD case of vexatious prosecution has just been published in the Belgian medical journals. In June, 1883, Dr. Velleman of Brussels was consulted by a lad of eighteen, who said that while lifting some heavy weight he had experienced a severe pain in the groin. On examination, Dr. Velleman found that, contrary to his expectation, the trouble was not of a specific nature, but that a very small inguinal hernia existed. This was reduced and bandaged, and the patient sent to an instrument-maker (who also felt the hernia distinctly) for a truss. Four days afterwards the mother came to Dr. Velleman and asked for a certificate of her son's complaint, nothing being said as to the use that was to be made of it. This she was given, the fee being two francs. The doctor thought no more of the circumstance till in the following August he received a summons to appear before a juge d'instruction, who showed him his certificate and told him that the lad belonged to the militia, and that he had been examined by the militia surgeons, who had stated that he had no hernia, and that he could not have had one as recently as June, so that the certificate was a false one. Dr. Velleman saw the lad, and examined him, and found that all traces of the hernia had disappeared. On being questioned by the juge d'instruction as to the exact nature of the hernia he had previously detected, he said that it was "une pointe de hernie inguino-interstitielle," by which he intended to convey the meaning of a hernia but slightly visible, pointing not through a natural opening in the abdominal wall, but through an accidental tear in the aponeurotic fibres. The medical jurists to whom the question was referred reported that there was no hernia, and that it could not have been cured in so short a time. The trial did not come on till March, 1884. His accuser stated that the certificate declared that the lad had a disease which he had not, and that when defendant, who gave such certificates at a cheap rate, found that this one was likely to cost him dear, he invented a name of a disease which was unknown, hoping by this "subtlety" to make people believe in its existence. A penalty of from two to five years' imprisonment was demanded. The court, however, without listening to more than the opening of Dr. Velleman's advocate's speech, acquitted him, and he thought his troubles were at an end. Unfortunately the Belgian law permits an appeal on the part of the prosecutor, and several months after the first trial the unfortunate practitioner had again to appear. For the trial in the Appellate Court he had taken the precaution of fortifying himself with letters from two eminent professors. The letter from Dr. Soupart, Professor of Surgery in Ghent, expressed the fullest approval of all he had done, and justified the term "interstitial" which he had employed; the writer also thought it was quite possible for the hernia to have been cured in two or three months. Another letter from Dr. Debaisieux, Professor of Surgical Pathology in Louvain, expressed a decided opinion that a hernia such as this, caused by a sudden strain in a young man and promptly treated, might disappear in a few days or weeks. "The hernia may probably have pointed through an accidental rupture in the transversalis fascia ..... and the application of a truss after the intestine had been replaced would permit this rupture to cicatrise." He also approved of the phrase used by Dr. Velleman as being appropriate, though not one used by medical authorities. The Court of Appeal confirmed the acquittal without even calling on the counsel for the defence. Thus, after nearly two years of anxiety and worry, Dr. Velleman is finally rid of all accusations and suspicions on account of this charge.

DEAD DOGS.

THE inventor of the lethal chamber, in one of his familiar addresses on the Balance of Natural Forces, gave his listeners the sentence, often since quoted, that "Nature, as chief of all the provident societies, provides that out of the very womb of death shall come the most perfect forms of life." It is not likely that he invented the lethal chamber to illustrate this argument, but it seems it does so marvellously well, as a Medical Officer of Health graphically shows in the *Daily News* of Monday last. The dead dogs from the chamber go down, it seems, to a farm near to London and are piled in heaps with straw and manure until they become fit for the land. One such heap was 30 ft. long, 15 ft. wide, and 6 ft. high. It contained several hundred dogs, and will be left undisturbed from four to six months to rot and decay. Then the heap will be turned over, and after the rotten bodies have been broken up will be reformed, to remain some months longer. Finally, it will be turned over again, and, every semblance of dog gone, it will be given to the land for corn and fruit, and it may be—total abstinence notwithstanding—British home-made wine, cider, and beer. In the transition there must be smell. The Medical Officer testifies to that in no measured terms. But he adds, "the men and boys who turn and cart this stuff seem none the worse for it," and as there are no residences within a quarter of a mile he sees no necessity for any interference. He is content to hope that the British public will enjoy the luscious "British queens and delicate early rhubarb which it gets from its transmogrified dogs." In this hope we join; but perhaps it may be better, as they increase, to spread out these wombs of death a little more widely, and to give them as much air room as may be obtainable for their transmogrification into the most perfect forms of life.

PHTHISIS IN FRANCE.

THE mortality from phthisis in Paris has amounted in two months to more than 1000, and it is reported that with the object of checking this excessive death-rate French *savans* are about to try the principle of inoculation, which under M. Pasteur's recent discoveries has been received with such extraordinary favour by French professional men. It is proposed to obtain subscriptions for a series of experiments, to be conducted on a large scale over a considerable area and for a period sufficiently long to make the results trustworthy. The influences of climate will be tested by the establishment of different stations for these tentative researches and operations. One of these stations is to be situated on the northern coast near Boulogne, another in the warmer temperature of the Riviera. Records will be kept of the various experiments, and a journal devoted to chronicling them. The support of several eminent medical men has

Digitized by Google

been already promised, and subscriptions in aid of the project have commenced to flow in. Whilst devoting itself chiefly to experiments on live animals by inoculation, the Society will also study to effect the alleviation of phthisis by the destruction of microbes.

THE BRAIN ACCORDING TO SEX AND AGE.

M. PH. REY, according to the *Revue Scientifique* (Jan. 30th, 1886), has communicated to the Société Medico-Psychologique the results of his analysis of the materials left by Broca. The following were the results of 347 observations collected by the learned anthropologist on the weight of the three cerebral regions, frontal lobes, occipital lobes, and parietal regions. Firstly, the relation of those different parts to the brain is:—

In Men.	
Frontal lobes	1 :: 2·33
Occipital lobes	1 :: 10·66
Parieto-temporal regions ...	1 :: 2·12
In Women.	
Frontal lobes	1 :: 2·32
Occipital lobes	1 :: 9·88
Parieto-temporal regions ...	1 :: 2·13

Secondly. In men the left frontal lobe is heavier than the right; but in the occipital lobes and in the temporal regions the excess is on the right side. Thirdly. In old people loss of weight is more perceptible in the parieto-temporal regions than in the frontal and occipital lobes; that is particularly the case in women. Hence it is that if in adult life men have proportionately larger frontal lobes, that ratio is attained in women in old age. Fourthly. In men the frontal lobes only attain their greatest weight at thirty-five years; but the parieto-temporal regions acquire it at twenty-five. The anterior lobes of women present little difference between twenty-five and thirty-five years.

CHOLERA IN BRISBANE.

WE have on several occasions drawn attention to the outbreak of cholera on board the Queensland line steamer, *Dorunda*, and we are now in receipt of communications from Brisbane which confirm the suspicion that the disease was true cholera. The disease manifested itself some days after the vessel touched at Batavia, and when it reached Cooktown certain cases of so-called dysentery were stated to be prevalent. These were doubtless the beginnings of the outbreak which was first reported from Townsville. When the vessel reached Townsville she was inspected by Dr. Ridgley, who reported certain cases and deaths, which, as the result of personal investigation, he regarded as "suspected cholera." Later on it appeared that quite a panic occurred amongst a large body of emigrants on board, and that the captain and the ship's doctor were all but disabled from the overwork occasioned in attending to the sick. Such a panic might have been expected when, instead of dealing with the outbreak at Townsville, it was decided by the Premier that the vessel should go on to Brisbane, the healthy and sick being thus confined together for a still longer period. The whole circumstances are typical of the blundering of the quarantine system. Those who maintain the efficacy of the system should at least be prepared to carry it out in a proper manner; but we read that one reason why the vessel was not allowed to discharge its human freight at Townsville was because it was raining hard, and the people would have required tents. But the action with regard to Dr. Ridgley is the most curious of all, reminding us as it does so forcibly of the useless and vexatious regulations to which the Turk adheres so fondly, and from which he derives a substantial income in the Red Sea. Dr. Ridgley had gone on board to aid the overworked ship's doctor with advice in forming a diagnosis, and it seems that he had gone to the vessel in an unauthorised ship. The result was that when he returned the people clamoured to have him put in quarantine, and the Mayor, in ordering him to confine himself strictly to his residence, added that it must be "together with all the members of your family," until the Colonial Secretary had been communicated with. It is curious to read such an order emanating from an office where it should at least be known that healthy men do not distribute cholera, and where it should be recognised that if danger does attach to an individual his family should be as much protected from it as the remainder of the community. Fortunately some better counsels are also prevailing in the colony, for people are being urged to carry out Mr. Simon's code of sanitary regulations in face of cholera emergencies, and writers to the public papers are pointing out the importance of cleanliness in all its forms. This will be of far more avail than the action which was followed of fumigating letter-bags and locking up doctors with their families because they perform the first duty which is required of them—namely, that of giving medical assistance to the sick. We knew that certain quarantine restrictions existed in the Australian colonies, but hitherto we were not aware that they were of so antiquated and vexatious a character.

THE TEREBENES.

So much attention has of late been directed to the subject of pure terebene as a medicinal agent, that it may be as well to remember that there is a group of substances known chemically as the terebenes. It is, in fact, the generic name for the volatile oils or hydrocarbons, isomeric or polymeric, with oil of turpentine. Nearly all the terebenes are liquid at the ordinary temperatures, and most of them are lighter than water. Natural terebenes treated with acids, especially strong sulphuric acid, generally undergo an alteration of molecular arrangement without change of chemical constitution, the odour being for the most part greatly altered. A terebene often yields several isomeric modifications by treatment with various acids or by repeated distillation with the same acid. The substance called pure terebene is made by the action of concentrated sulphuric acid on oil of turpentine. The process is an old one, and as far back as 1873 M. Riban read a series of papers on the subject before the Pharmaceutical Society of Paris. To prevent any misconception, it may be as well to state that the pure terebene used in the treatment of bronchitis is not a patent medicine; and that, as recently pointed out in the *Pharmaceutical Journal*, it may be made or sold by anybody without the slightest fear of infringing any patent rights.

DUBLIN HOSPITAL SUNDAY FUND.

FROM the report of the Council it appears that the total amount of contributions to the fund for 1885 was £4468 5*s.* 8*d.*, being an increase of £65 11*s.* 1*d.* as compared with 1884, while the working expenses for the year were represented to be £260 12*s.*, being 5·84 per cent. on the total collected. The Committee of Distribution for 1885, having ascertained that a sum of about £4000 was available, determined to distribute £3900 among the participating institutions in consideration of subscriptions received and work done, with an added bonus of 7½ per cent. to those institutions which had provided trained supervision for their nurses. The addition of this bonus absorbed a further sum of £279 2*s.*, making the total sum distributed for 1885 £4179 2*s.* The highest sum was awarded to the City of Dublin Hospital (£780 10*s.* 11*d.*), and the lowest to the Whitworth Hospital (£44 14*s.* 2*d.*). The relative expenditure in management and other expenses in the participating

Digitized by Google

hospitals was carefully considered by the committee, who arrived at the conclusion that in only one instance was the expenditure so disproportionate to the work done by the hospital as to call for inquiry. In this case, that of the Coombe Lying-in Hospital, the committee deemed that the expenditure on management was excessive, and the explanation they received they did not consider satisfactory, especially as among the items of management they found a sum of £100 as salary to the medical officer of the out-patient department, while no similar charge was discernible in the accounts of any other of the participating hospitals. In two cases—the Meath Hospital and St. Mark's Ophthalmic Hospital—the expenditure on provisions appeared to be too low—viz., at the rate of 8·742 and 7·197 pence per patient per day respectively; and in consequence of the committee's inquiries the Meath Hospital authorities are considering a revision of their dietary, and the authorities of St. Mark's had promised to bring the matter under the notice of the governors. As regards the Meath Hospital, some of the medical staff have for years past paid out of their own pockets for any extras ordered by them for patients under their charge, which of course effected a considerable saving in a year under the head of provisions.

SYPHILIS AT NISHNI NOVGOROD FAIR.

AT a meeting of the Syphilis Section of the Moscow and St. Petersburg Medical Society, a female practitioner who had been commissioned by the Government to inspect the common women frequenting the great annual fair at Nishni Novgorod last year communicated the results of her experience. There were two inspection stations, which were open from June 16th to Sept. 3rd; 2812 examinations were made of 355 women, of whom 49·3 per cent. were frequenting the fair for the first time and 27·7 per cent. for the second time. Some were professional prostitutes, and some servants and peasant women who only practised prostitution during the time of the fair, at other times living quiet lives in their own villages. It was found to be impossible to get the registered women to come up regularly for examination, even though photographs were taken of them. Of those examined, 6·2 per cent. had urethritis *(sic)*, 1 per cent. soft chancres, 0·2 per cent. hard chancres, 5·1 per cent. syphilitic condylomata, and 0·2 per cent. gummata, so that 5½ per cent. were found to be suffering from constitutional syphilis. The conclusions drawn were tolerably self-evident—viz., that the main cause of the spread of syphilis is public and private prostitution, such as that carried on at the fair; also that the examination regulations must be improved.

A PLEA FOR WEIGHING INFANTS.

DR. D. J. VIURA Y CARRERAS, medical officer of the children's department of a Barcelona hospital, has published some remarks on the importance of periodically weighing infants, by which observations it can be determined whether the mother's or nurse's milk is satisfactory in quantity and quality, and the desirability of a change is easily and early recognised. In the main Dr. Viura agrees with the statements of Bouchut—viz., that an infant loses from 100 to 200 grammes in the first four to six days, regaining its original weight in seven days, from which time to five months it gains 25 grammes daily, being then double its original weight, and this is again doubled at sixteen months. He made a series of observations on his own child, and concurrently with them tested the mother's milk by Donné's lactoscope. The child was born on December 16th, and on the seventh day weighed 3300 grammes. On January 15th it had gained 900 grammes; on February 2nd there was a further rise of 800 grammes; but on March 1st the gain was only 500 grammes, the explanation being that the milk, which up to February 10th had had a density of from 23° to 28°, had in consequence of the appearance of the menses decreased in quality, having a density of from 30° to 35°. It afterwards recovered its former quality, and during March and April the child increased respectively 850 grammes and 800 grammes. It is of course necessary to take into account any pathological condition which may be present, and not to attribute to the nurse what may be due to syphilis or tuberculosis in the child.

DIVIDED GOVERNMENT.

LAST Saturday Mr. Roberts, on behalf of the Metropolitan Board of Works, appeared before Mr. Mansfield at Marlborough-street, to answer a summons issued at the instigation of the St. Giles' Board of Works, to compel them to abate a nuisance at Denmark-street, Soho, which had been acquired by the former board on Jan. 31st for the purposes of demolition, and from which the water-supply had been cut off. The miserable condition into which houses fall which are included in any improvement scheme is known to all persons who have had experience of the action of the Metropolitan Board of Works in dealing with property under the Artisans and Labourers' Dwellings Improvement Acts. It cannot be expected that landlords will expend money upon houses within a few weeks of their passing out of their hands, nor would it be profitable for the Metropolitan Board of Works to repair houses which in a very short period will be demolished; but the continued occupation of these places should be prohibited, and if the action of the St. Giles' Board quicken that of the Metropolitan Board in this respect they will have done London a service.

PROFESSOR VIRCHOW ON PATHOLOGY AND DARWINISM.

IN an article contributed to the current number of his *Archiv* Professor Virchow replies to some views enunciated at the Strasburg Conference of German Naturalists and Physicians by Dr. Weismann upon Darwinism and Pathology. The question gains in interest from the facts adduced by Mr. Sutton in the first of his recent lectures before the College of Surgeons, for Professor Virchow's contention is the same as that of Mr. Sutton—viz., that variations from the animal type are largely brought about by deviations in structure strictly speaking pathological. Dr. Weismann, on the other hand, contended that such variations are the result of the law of adaptation, and it is this position which Virchow contests. He points out that Darwin himself, although not a pathologist, recognised the want of a clear line of distinction between monstrosities and mere variations. Weismann, however, went so far as to deny the inheritance of *acquired* properties; but it is difficult to see how otherwise one is to express the changes induced by adaptation to the environment. The facts of acclimatisation are, as Virchow points out, instances of such adaptation, and colonies could not be founded if it did not happen that the powers so acquired were transmissible to posterity. Weismann, on the other hand, regards acclimatisation rather as the product of selection, such individuals surviving who, by the possession of inherent qualities, are enabled to live under the changed conditions, and not that they acquire new powers. Much, however, turns upon what is meant by an acquired quality. Weismann means by it such as is imparted by some external agency and would limit the influence of external causes to unicellular organisms, whereas variation occurs through sexual reproduction. But, as Virchow points out, external agencies ought not to be limited to those which operate outside the organism. In a multicellular organism variation may occur in some cells through the operation of other cells—i.e.,

Digitized by Google

strictly within the body. Indeed, the influence of the sperm-cell upon the germ-cell is an external influence, and therefore, although we commonly speak of inherited qualities as being internal or predisposing, in strictness the qualities transmitted from the male parent are the result of an external agency when contrasted with those derived from the germ-cell. Applying these considerations to pathological processes, he shows that these are the result of external agents, and that they produce a change in the typical organisation, and thus by mere analogy the conclusion is arrived at that many racial—nay, even specific and generic—differences have been brought about by processes which may be deemed pathological. The various factors which determine the persistence of such deviations, and their transmission by inheritance, are not fully known; use and disuse explain some, adaptation accounts for others; but however explained, the fact that acquired qualities are inheritable remains assured.

THE JUBILEE OF THE UNIVERSITY OF LONDON.

IT has been proposed to mark the fiftieth year of the foundation of the University of London by a commemoration, either in the form of a banquet or otherwise. The proposal originated with the Masonic lodge of the University, and was discussed at the last meeting of the University Dining Club, where a committee was formed to consult with the annual Committee of Convocation and the Senate upon the best means of carrying the proposal into effect. It may be remembered that in 1828 what is now University College was founded as the University of London; but it was not until eight years later that the present University received its charter. Members of the Medical Faculty of the University will, we are sure, co-operate in such a celebration, for in no faculty has the University been more distinguished by the number of eminent men who have graduated there. The fact that one of its legal graduates has just received the highest distinction in the realm open to his profession appropriately signalises the jubilee year, and the suggestion that Baron Herschell should preside over the commemoration is one which will be heartily received.

UNLABELLED POISONS.

IT is still far from uncommon to find that accidents occur from the unguarded use of medicinal poisons by inexperienced persons. The case lately investigated by the coroner for Central Middlesex, in which a woman poisoned herself with her husband's liniment, must have been noticed by many of our readers. The mixture used, though exceedingly powerful, since it contained a large quantity of aconite, had been dispensed and forwarded from a distance without a label. In another quite recent case a boy was poisoned with carbolic acid through the unfortunate forgetfulness of his nurse, who had put some of the disinfectant in an empty medicine bottle for convenience' sake, and administered it to him in mistake by the mouth. These very regrettable incidents teach us that a danger which appears to some almost too common and too evident for precaution, is dormant among us, and may at any time effect most serious injury. In view of the facts above mentioned, it may well be doubted whether the poison label and the dark blue bottle, familiar warnings when seen, are not far less usual in practice than approved in theory. Ordinary caution surely requires at least the employment of these distinctive signs. The professional chemist is under obligation to use them, though to a less extent than he might be. The public are not, nor is the dispensing practitioner. The latter, we are inclined to think, would not lose but rather gain, as would also his patients, if he were required to affix to pure poisons or highly poisonous liniments, some mark which should ensure the proper estimation of their power of doing harm when misapplied. It might be less easy to impose any effectual restriction of this kind upon the careless handling of poisons by non-medical persons in general. We may, however, conclude that one great public advantage would arise from such wide extension of precautionary measures—namely, an arrest, at least partial, of the very free circulation now allowed to nostrums of uncertain composition.

WHOLESALE MEDICAL WORK AND ITS REMUNERATION IN THE THREE TOWNS INSTITUTION.

As an act of justice to the executive of this exacting institution we inserted last week a letter from the chief executive officers, who said *inter alia* that their chief medical officer, Dr. Keily, had "a position equal to a private practice of £400 a year." The letter of the executive to us having been published in the *Western Daily Mercury*, Dr. Keily has written a reply to our contemporary. From this reply we extract one paragraph which ought to enlighten any inexperienced and impecunious young man who thinks of taking the post vacated by Dr. Keily; and it ought to enlighten the public and the working classes on the ungenerousness of asking such enormous labour for such inadequate and declining remuneration as is represented in 30,000 cases at the rate of 1¼*d.* per case! The following is the paragraph alluded to:—

"It is stated that my position is worth £400 per annum. This is glaringly false. For services rendered I receive the following:—Residence, free of rent, rates, taxes, say £60 (which is certainly more than the value of the apartments I occupy); salary as medical officer, £180; midwifery (148 cases for 1885), £77 18*s.*; total, £317 18*s.* I have to provide my own furniture and all the instruments required in a general practice. The fees for extra certificates have not amounted to fifty shillings in the three years. As 10*s.* 6*d.* per case is the fee for midwifery, I will deduct the £77 18*s.* from the gross amount, which leaves me £240 as payment for consultations and visits. My salary and allowances are the same now as they were three years ago. In 1883 for 16,883 cases I received 3¼*d.* and a fraction per case; in 1884 for 27,429 I received 2*d.* and a fraction per case; and in 1885 for (in round numbers) 30,000 I received 1½*d.* and a fraction per case; so that, with the gradual wearing down of my physical strength, my income practically was on the decline. This is certainly a small chapter on wages for Leone Levi or some annotator of Mill to examine. In reckoning that 30,000 out of the total for 1885 came to me I have had the consent and assistance of my late colleague, Dr. Rees."

MADRAS CIVIL HOSPITALS AND DISPENSARIES.

IN publishing the report by Surgeon-General Furnell on the civil hospitals and dispensaries of Madras, the Chief Secretary to the Government remarks that "the bulk of the report might be largely diminished. In future not only should the appended extracts.....be omitted, but also the long extracts from the reports of district surgeons, the matter contained in which comes before Government in individual municipal and local fund reports. The extracts referred to do not in any case form the text on which any representation is now made." We feel bound to say that we fully concur in this opinion, for the great mass of the appendix, extending to 244 pages, appears to be of no practical value. The report itself covers only fifteen pages, and gives a summary of the work done. There were throughout the presidency 299 hospitals and dispensaries, with a staff of 299 agents, including all grades. During the year there were 39,826 in-patients and 1,714,072 out-patients treated; of the former, 3100, and of the latter 6907, died. Of the out-patients, 5310 died of cholera, and 425 of the

Digitized by Google

in-patients. The returns show a total of 14,588 cases, with 5735 deaths, or one in 2·54 cases. Next to cholera, dysentery and diarrhœa were the most fatal diseases among the in-patients, and fever among the out-patients. We trust that in future reports a judicious summary of events may be given, and the unnecessary printing of the numerous minor returns from dispensaries and uninteresting extracts from the reports of the surgeons, apothecaries, and hospital assistants, be omitted.

THE ETIOLOGY OF RACHITIS.

DR. H. C. HAVEN, of Boston, has noticed that among the children attending the West-end Dispensary for Children in that city, rickets is much more common among the coloured than the white population. His inquiries show that this increased frequency of rickets is not due to difference in the mode of feeding, to overcrowding, to worse hygienic conditions, or to ill-health on the part of the parents. Dr. Haven is inclined to attribute the fact to the natural habitation of the coloured races being much further south than North America, and that they have "an inherited necessity for heat and sun," which the Boston climate does not satisfy. In confirmation of this view he states that of "the white rachitics of a foreign ancestry, the majority are born of parents coming from the south of Europe, where the disease is relatively rare, rather than of parents from England and North Germany, where the disease is rife."

FEROCIOUS DOGS AND THE LAW.

MANY legal decisions give the public a very unsatisfactory estimate of the law. A poor woman at the Marylebone Police-court the other day consulted Mr. Cooke in reference to injuries she and her child sustained by a dog which accompanied a young woman, a servant in a gentleman's family, who came to ask her about some work she required to be done. While speaking to her the dog seized her little boy's face and dragged the flesh away. The dog then bit her, and again seized the boy by the leg as she carried him off. To any mind but the legal one here was proof enough of the most unmitigated ferocity; but Mr. Cooke, said the law, which he allowed was in a disgraceful state, required proof that the dog had injured someone before, and was known to the owner to be ferocious. It is the very essence of these cases that in the estimation of the owners these animals are always of the most amiable temper, and their little peccadilloes are due to a want of tact or address on the part of the persons they bite. It is most aggravating, when you have just escaped—or perhaps have not escaped—a bite or possibly hydrophobia, to have the amiability of the dog insisted on. But this is what happens in nine cases out of ten; and it has Mr. Cooke's support. In all conscience there was proof enough of ferocity in this case; but the gentleman and his dog go free, and the poor woman and her child get torn and bitten without redress.

PTOMAINE IN STALE FISH.

LAST year several cases of poisoning by stale sturgeon occurred at Kharkov; five terminated fatally. Anrep, studying the cause of these accidents, showed that a ptomaine was the efficient cause, and could be extracted from the fish, as well as from the contents of the stomach and intestines, the liver, blood, brain, and urine of the victims (*Revue des Sciences Médicales*, No. 53, p. 66). The alkaloid differs from the ptomaines of Brieger. It is an amorphous, highly alkaline body, forming soluble salts, and extremely toxic. Caustic agents and boiling destroy the toxic power of the alkaloid, which has two chief characters,—viz., its fixity whether in the solid state or in etherial solution, and the slowness of its reducing action on the blood. The hypodermic injection of a quarter of a milligramme in a dog causes vomiting, mydriasis, general prostration, and slowness of the movements of the heart. In the rabbit the action is much more rapid, and the above-mentioned dose causes death in two hours. The march of the symptoms in the poisoned individual is in harmony with the results of physiological research, and indicates, according to Anrep, that the poison first paralyses the spinal cord, then the medulla oblongata, and acts probably also upon plain muscular tissue.

THE VALUE OF QUARANTINE.

DR. J. D. THOLOZAN, who for nearly thirty years has resided in Persia, and who has devoted much of his time to the study of epidemiology, has recently contributed a paper of considerable value to the Académie des Sciences of the Institut de France on the question of quarantine restrictions in their influence on plague and cholera. His whole paper goes to show that, if not absolutely useless, they are practically worthless, and that deductions as to their value which are made elsewhere are not warranted. To cite an instance quoted by him: He points out that the ports in the Persian Gulf are in uninterrupted communication with British India, and especially with Bombay, which is generally regarded as one of the great cholera centres. He gives a description of these ports, showing how, by reason of their soil, moisture, the poverty of the people, and otherwise, they correspond precisely to those places where cholera is said to be locally engendered and maintained; and then he explains that not only has no quarantine ever been put in force there, but Persia has not even the means of carrying out any such precautionary measures. Then it is added that since 1821 cholera has never entered by any of the ports in question. Now, it is not very long since a quarantine system was advocated in the Persian Gulf, with a view of protecting the adjoining countries and Eastern Europe from invasion by cholera in this direction, and Dr. Tholozan very aptly says that if these measures had been put in force, the experience of the Persian Gulf would be uniformly quoted as affording strong evidence of the value of quarantine restrictions. He asks that those who bring forward proof every now and then as to what quarantine has effected in the Red Sea during those years in which cholera has not spread by that route should remember how, in olden days, physicians attributed cures to remedies which we now know to have been so useless and injurious that they have been altogether abandoned.

VACANT PROFESSORIAL CHAIRS ABROAD.

THERE are now no less than four professorships vacant in the Medical Faculties of the Universities of Kieff, Kazan, and Kharkoff: Dr. Mering, Professor of Special Therapeutics in Kieff, having resigned on account of ill health; Dr. Subbotin, Professor of the Therapeutic Clinic in Kazan, having resigned, after twenty-five years' service; and Dr. Vinogradoff, Professor of Clinical Therapeutics in the same University, having recently died; while, lastly, the chair of Special Pathology and Therapeutics in Kharkoff has just been resigned by Professor Kremyanski.

THE PECULIAR PEOPLE AND THEIR CHILDREN.

THE Peculiar People are perhaps more to be pitied than blamed when their peculiar abhorrence of human help in sickness recoils with injury upon themselves. When, again, they exercise in the spirit of their creed the responsibility of parents for their children, they clearly lay themselves open to indictment. The other day, at Grays, in Essex, a child whose parents belonged to this sect died from the effects of pneumonic inflammation, unattended by any

Digitized by Google

medical practitioner. Such a condition is obviously well within the effective range of modern medicine, and there was doubtless much reason in the medical opinion delivered at the subsequent inquest that the child's life might have been prolonged or saved by timely measures of treatment. We therefore fully concur in the jury's recommendation to the local Board of Guardians thatthey should take summary means to convince the father that his wilful neglect was a legal offence.

ROUGH PLAY AT FOOTBALL.

IT is satisfactory to note that, after all, efforts are actually sometimes made to keep within bounds the "free fight" element which unhappily characterises the game, or rather we should say both games, of football as at present played. The Birmingham and District Football Association have taken, it is stated, a determined step for the suppression of rough play at matches. At a meeting held on the 10th inst. they suspended two players for brutal behaviour at a recent match, and expelled another. A strong feeling was expressed that such conduct should be put down, as several players have been injured. Although these steps were not taken until after the players had been fined by the magistrates for assault, we say, All honour to Birmingham. No one being likely to accuse the inhabitants of the great midland town of being "sickly sentimentalists," we trust that the more timid authorities in London and the North will rouse themselves and follow this needed example. It seems no sort of use appealing to the great central authorities, the Rugby Union and the Football Association. In the latter game there can be little doubt that the contest for the Cup, for which we believe about one hundred and forty clubs this year entered, has much rough play to answer for. The introduction, too, of professionalism is much to be deprecated. In most games and sports the amateur and professional elements are kept apart. For instance, if an amateur, as was lately exemplified, runs a race against a professional he loses his amateur status. Surely football is the very last game in which paid players should be allowed to compete. We do not believe that the great roughness of the play and the enormous popularity of the game are cause and effect. There is plenty of interest in football apart from the free fighting. The game is in many ways too good a one to "end," but it must be "mended." Will it need one or two verdicts of "manslaughter" to effect this?

GERMAN MEDICAL CONGRESS.

THE fifth German Congress for Internal Medicine will take place, from April 14th to 17th, at Wiesbaden, under the presidency of Professor Leyden. Papers on the Pathology and Treatment of Diabetes Mellitus, the Operative Treatment of Pleural Effusion, and the Treatment of Syphilis will be read; and others have been promised on the following subjects: Antipyresis, Ptomaines, Heredity in some Diseases, and Fluctuations of Blood-pressure in the Cardiac Ventricle during Narcosis from Morphia.

TYPHUS IN ENGLAND.

WE referred last week to a prevalence of typhus at Leeds, and some of the annual and other reports now coming to hand go to show that the infection of this disease has been scattered about in several of the large centres of population during the past year. Thus, Dr. Tatham points out that at Salford fifteen cases were observed in the first quarter of the year, thirteen in the second, and one in each of the third and fourth quarters; the disease having again and again been imported from without into some of the most unhealthy portions of the district; but fortunately it was held in check by means of immediate isolation and thorough disinfection. So also at Carlisle the disease made its appearance, but, in view of the past history of the city as regards typhus, prompt measures were at once taken to check it. Both Salford and Carlisle have sanitary hospitals and disinfection appliances; hence doubtless the satisfactory results they are able to record in stamping out typhus.

INHALATIONS OF BLOOD.

FOR anæmic patients in whom the preparations of iron are ill tolerated, M. Fubini avails himself, with marked benefit to the patients, of pulverisations made of a mixture composed of 80 parts of a solution of chloride of sodium (¾ per cent.), and 20 parts of defibrinated ox blood. An ordinary spray suffices for carrying out the procedure, which may be repeated without danger five or six times a day, each inhalation lasting about fifteen minutes. Each sitting ought to use up about twenty cubic centimetres of defibrinated blood. The patients experience, after having taken several deep inspirations, a slight giddiness, which disappears on assuming the horizontal position or after drinking a glass of wine. Absorption takes place rapidly from the respiratory passages. M. Fubini remarks on the perfect tolerance by patients of the inhalations, and on the certainty with which hæmoglobin is absorbed by the respiratory passages.

A LUNATIC IMPRISONED AGAIN.

WHY do the City Fathers persist in imprisoning Herbert Percy Freund, seeing that he is certainly "a person of unsound mind"? Is it that they deem it less costly to keep him one-third of his time in gaol than to maintain him altogether in an asylum? The question of humanity ought to have some little weight as against the question of economy. Besides which, it may one day happen that this lunatic will no longer be contented with declaiming against St. Paul's Cathedral as "that house of idols over there." He may turn iconoclast on his own account; or, instead of predicting the downfall of the City, he may do something towards the fulfilment of his prophecies. The policy of the City magistrates is neither sound nor safe, and it is certainly anything but benevolent.

A PORTUGUESE METHOD OF TREATING RINGWORM.

RINGWORM of the most obstinate character may, according to Dr. Saerlis, writing in the *Medicina Contemporanea* of Lisbon, be cured in ten days by cutting the hair from the affected spot, pouring turpentine on it, letting it run over the whole head, and rubbing well with the finger. After this has caused a smarting sensation for from three to five minutes, it is washed off with carbolated soap. Hot water is then used for washing the whole head, and the affected spots touched with dilute tincture of iodine or with a 2 per cent. solution of iodine and turpentine. This process is to be repeated once or twice a day.

EASTER VACATION COURSES IN GERMANY.

DURING the Easter vacation special series of short courses of lectures and practical demonstrations are arranged to be delivered at Berlin and Würzburg. Those in Berlin commence on the 22nd of March and continue till about the end of April; those in Würzburg commence on March 15th and last five weeks. Information about the Berlin courses may be obtained by writing to Herr Anders, 57, Dorotheenstrasse, Berlin. Information concerning the courses in Würzburg could probably be obtained from any of the lecturers—e.g., from Dr. Rosenberger (who is to give the course on bandaging, &c.), Hofstrasse, Würzburg, Bavaria.

Digitized by Google

MESSRS. CROOKES, ODLING, and TIDY, reporting on the composition and quality of daily samples of the water supplied to London during last mont , state that they analysed 117 samples collected from the mains of the seven water companies taking their supply from the Thames and the Lea, and that the whole were found to be perfectly clear, bright, and well filtered. Despite the flooded state of the rivers, there was not any appreciable increase in the proportion of organic matter present in the water-supply of the month; the mean amount of organic carbon found in the Thames-derived supply being ·183 part in 100,000 parts of water, as against a mean amount of ·170 part in the preceding month. For some time past they have been directing their attention to the examination of the water of the metropolis by so-called "biological methods," from the application of some of which, at any rate, results of importance may ultimately be arrived at; but several months at least, they state, may be expected to elapse before they are in a position to include any results furnished by this manner of examination in their ordinary reports.

ON Thursday, the 11th inst., Mr. Paul Swain amputated at the shoulder-joint for a very large and rapidly-growing cystic sarcoma, in a lad of nineteen. It was thought to involve the scapula, and the preliminary incisions were made with a view to remove that bone with the humerus. On opening the shoulder-joint, however, the disease was found to be confined to the humerus, and amputation at the shoulder-joint was completed. Owing to the size of the tumour the difficulties and dangers of the operation were considerably enhanced; but with the valuable assistance of Mr. Whipple and Mr. W. Square very little blood was lost. The patient has rallied well from the shock of the operation, and bids fair to make a good recovery.

FOR some time past there has existed in America considerable dissatisfaction with the manner in which the Johns Hopkins bequest is handled. Some months ago an effort was made by the minority of the trustees to have the University opened, but they were outvoted. The same trustees, knowing Mr. Hopkins' wishes in the matter, desired the University to be located at Clifton, the country residence that Mr. Hopkins donated for this particular purpose, but this proposal was also rejected. Now, we understand, a Bill has been introduced into the State Legislature asking that a committee be appointed to ascertain whether the wishes of Mr. Hopkins have been carried out or not.

THE question of the fitness of the present buildings of the Melbourne Hospital for the reception of patients is again, after an interval of four years, under discussion. We understand that the honorary medical staff of the institution have laid before the Committee of Management their opinion of the present capabilities of the building, and by pointing out its deficiencies have relieved themselves from the responsibility of tacitly acquiescing in the continued use of an insanitary structure.

MESSRS. CASSELL AND CO. will publish during the current month, in three volumes, a Manual of Surgery, which has been edited by Mr. Treves, and is intended to form a complete, concise, and authoritative treatise on the science and art of modern surgery.

A MEETING of the President and Council of the Royal College of Surgeons in Ireland will be held this week to elect a curator to the museums of the College, in the room of Mr. Abraham. The salary attached to the post is £250 per annum.

WE regret to learn that by a fire which occurred a few days ago a large number of the anatomical preparations belonging to Mr. Thomas Cooke, and which had been accumulating for the last fifteen years, were destroyed, and also a portion of Mr. Cooke's school premises. All the new and more spacious part of the building is, however, uninjured, and we are glad to learn that the work of the various classes has not been interrupted.

THE special committee of the Liverpool dispensaries intend, at the next annual meeting of the subscribers to these institutions to be held on the 25th inst., to recommend the abolition of the office of honorary medical officers, and that the whole of the medical work be in future performed by one head surgeon and two assistant surgeons at each dispensary.

MR. ROBERT DE'ATH, a surgeon residing at Buckingham, died suddenly on the 11th inst. He had just returned from visiting a patient, and fell in the hall of his own house, death, it is supposed, resulting from apoplexy. The deceased held the offices of coroner for the district and medical officer of health for the borough and union.

ON the 16th inst. the Bedminster Board of Guardians passed a resolution expressive of the sympathy they felt for the loss which the family of the late Mr. G. Pizey had sustained by his recent death. Mr. Pizey had acted as medical officer for the Clevedon district of the union for twenty years.

THE Municipal Council of Marseilles has voted a sum of 60,000 francs for the relief of those families who have suffered from the small-pox epidemic now prevailing in that city.

WE are glad to be able to say that we seem to be approaching within a measurable distance of the end of the Bower and Keates case. We trust shortly to make a more definite statement on the subject.

Pharmacology and Therapeutics.

ACETOPHENONE.

MM. MAIRET and COMBEMALE have continued their investigations on acetophenone, healthy and insane individuals being the subject of experiments. On healthy men doses varying from ·10 to ·30 gramme, administered by injection into the stomach, caused no disturbance of any function; in larger doses, ·45 to ·60 gramme, the circulation and micturition were affected. Micturition became more frequent during the first moments after the administration, and the pulse, at first very full without changing its frequency, became, five or six hours after the administration, more compressible and a little less frequent. Experiments were made on various insane individuals, most of whom presented excitement of some kind. The dose varied from ·10 to ·45 gramme every twenty-four hours. Some of the patients took this drug for eleven consecutive days; others only for five or six days. The patients suffered from epigastric sensations of heat, and in other cases a diminution in the amount of hæmoglobin was observed. Although true hypnotism was not noted, still many of the patients were less excited under the influence of the medicine. The authors regard it, however, as of no value for procuring sleep.

COLCHICINE.

A valuable contribution to the study of toxicology has been made by M. Houdé, and may be consulted in the *Répertoire de Pharmacie*, No. 1, 1886. The chemical characteristics of crystallised colchicine and its clear differentiation by the aid of certain reactions have enabled M. Houdé, by

Digitized by Google

means of experimental methods, to discover the poison everywhere in the tissues and liquids of the economy. He has thus been able to draw up a scale showing the directions in which the poison is eliminated. In this scale the stomach and intestines amongst the solid tissues hold the first place, and amongst the fluids the diarrhœal stools, the urine, and the saliva (dog). The poison has not been detected by chemical research, in the tissue of the heart, but the experimental symptoms—much more delicate tests—have clearly shown its presence, though in relatively minute quantity. Chemical and physiological investigations of the circulating blood have proved the absence of the poison from this fluid. Finally, the substance of the muscles, notably of those that surround the articulations and the tissues of the joints themselves, including the osseous substance, contain, as proved both chemically and physiologically, a notable proportion of the toxic agent. This last fact possesses an interest altogether apart from questions of a toxicological or forensic nature, having a far more important bearing on the mode of action of colchicine in therapeutics.

CONTRADICTORY OPINIONS ON HOPEINE.

Two very contradictory sets of views have been recently expressed by eminent French observers on the nature and value of the drug hopeine. Dr. Ch. Eloy, of the Hôpital Bichat Laboratory, reports, after thoroughly investigating the substance by giving it to animals himself, and after a number of clinical observations made by M. Henri Huchard, that hopeine "is a hypnotic drug, only slightly poisonous, fairly trustworthy, and indicated in cases where opium cannot be prescribed; useful, also, where the insomnia is not caused by pain." M. Dujardin-Beaumetz, on the other hand, stated at the Académie de Médecine that "the white powder sold at a much higher price than morphia is nothing but morphia scented with hops. It gives precisely the same reactions as the latter alkaloid, so that either hops must contain morphia, or, as I believe, the sale of hopeine is an impudent fraud." Another member remarked that he had just been translating an article on hopeine in which it was declared that it could only be obtained from hops grown in Central America. M. Gautier capped this with a story of what had occurred to himself some time ago, when he obtained at a high price some "cobra poison in glycerine," which, to his dismay, he found to be glycerine pure and simple!

URETHAN.

It will be remembered that urethan or urethane has been recommended as a hypnotic. Schmiedeberg has a most interesting article in the *Archiv für Experimentelle Pathologie und Pharmacologie*, in which he deals with the pharmacological action and therapeutics of some of the ethers of carbamic acid; urethan is the ethyl salt of this acid. Solutions containing 10 to 25 per cent. of this ethyl carbamate produce insensibility, precisely as occurs in the anæsthesia of chloroform; but the respiratory movements appear to be increased in frequency and force, a possible effect of the influence of the amidogen group; the heart appears to be unaffected by urethan. The new hypnotic cannot be used for surgical operations, but may replace the nauseous paraldehyde and chloral, where it is wished to avoid the action of chloral on the heart and respiration.

BENZOATE OF COCAINE.

Señor Alfredo Bignon, in a paper read before the Lima Academy of Medicine, and published in *La Cronica Médica*, strongly recommends the employment of the benzoate of cocaine in preference to the hydrochlorate (the salt most commonly used), and to the salicylate and borate, with which he has also made experiments. He finds that the benzoate is extremely soluble, easily crystallisable, and retains the characteristic odour of coca itself. The antiseptic qualities of benzoic acid also are an additional advantage. Amongst other experiments, the anæsthetic effects of a 20 per cent. solution of the benzoate were compared with those of a similar solution of the hydrochlorate in a case of epithelioma of the tongue, with the result that the effect of the former salt persisted for a much longer time than that of the latter.

TYRONE INFIRMARY.—Dr. Andrew Buchanan has been appointed resident surgeon to this institution. Dr. Buchanan was educated at the Queen's College, Belfast, and obtained a scholarship or exhibition each year during his course in arts and medicine.

STATISTICS OF SUICIDE IN ENGLAND.

AT the Statistical Society, on Tuesday evening last, Dr. William Ogle, of the Registrar-General's office, read a paper on Suicides in England and Wales, in relation to Age, Sex, Season, and Occupation. As regards the basis of facts dealt with and the mode of treatment, Dr. Ogle's statistics exceed in trustworthiness and in interest any previously available figures dealing with this subject. The paper and its accompanying tables deal with the suicides of 42,630 persons, whose deaths were so returned in England and Wales in the twenty-six years 1858-83. It is pointed out that this number of suicides is considerably below the true number, as no reasonable doubt exists that numbers of deaths ascribed to accident, or returned by coroners under the open verdict of "Found dead," are cases of suicide. With reference to this disturbing element in suicide statistics, Dr. Ogle remarks that there appears "no reason to suppose that the under-statement thus caused will be greater in one sex than in the other, or in some age-periods or in some occupations more than in the rest." In relation to age, it appears that during the twenty-six years the deaths of one or two children aged between five and ten years were referred to suicide, but that very few suicides occur under fifteen years of age; after which age the death-rate from this cause increases at each successive age-period, in each sex, until the maximum is reached at the age-period fifty-five to sixty-five, after which it declines again. The age-incidence of suicide corresponds generally with the lunacy-rate, measured by the age of admission to asylums. The maximum lunacy-rate is, however, reached at an earlier age than is the suicide-rate, and its after-decline is less regular.

The variation between the suicide-rate of males and females is very wide. The annual death-rate of males from this cause in England and Wales in the twenty-six years under notice was 104 per 1,000,000 living, while the rate among females was only 41. These figures, however, do not fully represent the different liability of males and of females to suicide. Corrected for the different age distribution of the two sexes, the female suicide-rate is reduced to 39, and it is shown that in equal numbers living, of equal ages, the true proportion of mortality from suicide is 267 among males to 100 among females. An interesting table in the paper shows that the male and female rates from suicide diverge more widely with the advance of age, with two exceptions. At the age of fifteen to twenty the suicide-rate among females actually exceeds that among males, the rate, however, being low at these ages in both sexes. Again, at the age-period forty-five to fifty-five, the excess in the male compared with the female suicide-rate shows an exceptional diminution, and breaks the continuity of the increasing divergence between the male and female rates at successive age-periods. These two exceptions are, with reasonable probability, referred by Dr. Ogle to physiological causes, due respectively to "the conversion of the girl into the woman," and to the effect upon the "female system by the menopause or 'change of life.'" The suicide-rates at the different successive groups of ages show considerable agreement as to increase and decrease with lunacy-rates, measured by the proportions of persons admitted at each age-period into asylums under the observation of the Lunacy Commissioners.

The most original and the most valuable part of Dr. Ogle's paper deals with the suicide-rates in relation to occupation. Not only is the basis of facts from which the conclusions are deduced larger than that which has before been used for a similar purpose, but Dr. Ogle's method of treatment is one which is beyond cavil. The rates from suicide in the different occupations are calculated on the numbers engaged therein, as enumerated at the census in 1881, while the suicides were those registered in England and Wales during the six years 1878-83. Moreover, due correction is made for the varying age distribution of those engaged in the different occupations. The necessity for such correction is conclusively pointed out, and must be evident to anyone who has given this branch of the subject any serious consideration. It is shown in a valuable table that the annual death-rate from suicide among all males in England and Wales, aged twenty-five to sixty-five years, during the six years 1878-83, was equal to 222 per 1,000,000 living. The suicide-rates prevailing,

Digitized by Google

however, among those engaged in forty-three occupations or groups of occupations ranged from 74 among miners, 96 among shipwrights and shipbuilders, and 139 amongst clergymen and ministers, to 407 among butchers and fishmongers, 408 among barristers and solicitors, 444 among chemists and druggists, 472 among medical practitioners, 474 among innkeepers and publicans, 650 amongst inn and hotel servants, and 1149 among soldiers. The most marked features presented by these statistics support the general impression that suicide is more prevalent among the educated than among the uneducated classes, and Dr. Ogle points out that during the last quarter of a century the rate from suicide has increased in England concurrently with the increase of education, measured by the ability of persons to sign their names in the Marriage Register. Dr. Ogle urges, however, that "it must not be necessarily concluded that this increased tendency to suicide is the direct consequence of education, and of its effect upon the nervous system." In dealing with suicide in relation to season, the popular error in believing suicides to be most frequent during the fogs and depressing weather of November is once more exposed, and it is shown that the suicide-rate is actually at its minimum in November and December, while it increases with the length of daylight, and reaches its maximum in June. The last section of the paper deals briefly with the methods of suicide, which, as Dr. Ogle admits, "is rather a subject of curiosity than of any higher interest." It is shown, however, that the method of suicide is mainly determined by the comparative freedom of access to the several means or instruments used for the purpose. Soldiers, for instance, preferentially select the gun; while by far the largest proportion of medical men and chemists select poison as the means for effecting suicide; among photographers, moreover, more than 85 per cent. of the recorded suicides were due to cyanide of potassium.

Dr. Ogle admits, in conclusion, that he was much tempted in places to compare the English suicide figures with those of foreign countries, but a careful examination of Morselli's laborious treatise on the subject convinced him that the materials he used for the purpose were too heterogeneous in form and numerically insufficient to afford thoroughly trustworthy conclusions. He trusts, therefore, that foreign statisticians will take up the subject, and treat it with as much care and labour as he has devoted to the English statistics of suicide. International suicide statistics will then afford the means for useful comparison, and throw more light upon an interesting branch of the subject—the influence of race and national temperament upon the tendency to suicide.

MEDICAL HISTORY OF THE SUAKIM EXPEDITIONARY FORCE.

SURGEON J. R. FORREST, of the Army Medical Staff, favours us with the following communication on the above subject:—

"Two circumstances were especially noticeable in the medical history of the Suakim Expeditionary Force—viz., the occurrnce of very high bodily temperatures, and the production and propagation of enteric fever apart from the contamination of water or the food supply. The excessively high bodily temperatures above mentioned were found in cases of sunstroke, and more particularly in cases of "heat apoplexy," or the cardiac variety of the disease, where the patient had been seized when not directly exposed to the sun's rays. I had several cases under my own care, and have seen similar cases under the care of other surgeons, where the temperature in the axilla very rapidly mounted up to 109·6°. The general history of all such cases was as follows:—The patient was admitted a day or two previously with the symptoms of sunstroke (with moderately high temperature, 104° to 106°) or quite as frequently he had come into hospital with some ailment of a totally distinct nature—e.g., whitlow, fractured femur, occurring four weeks before the supervention of the high temperature in question, dyspepsia, &c. The orderly in charge of the ward would bring word that the patient's breathing was becoming rapid, and that general convulsions were developing. On examination, the patient's skin would be found pungently hot; temperature in axilla up to 109°·to 109·6°; the patient at first conscious, but rapidly losing sensibility; breathing rapid and shallow; face perhaps cyanosed; and very soon general convulsions were well marked. I had one such patient, who was originally admitted with whitlow, and who subsequently had three distinct attacks of heat-stroke at intervals of three or four days to one week, and this patient could tell from his own sensations when an attack was approaching. Very many of these cases recovered. One remarkable case of recovery was under the care of Surgeon-Major Bate, medical staff, on the hospital ship *Bulimba*. This occurred in the beginning of June, when the temperature in the 'tween-decks was 92° to 95°. The patient was suddenly seized with the symptoms above described, and his temperature in the axilla reached 108·6°. Surgeon-Major Bate assiduously rubbed the patient's body with ice and administered quinine and brandy in enemata, and the following morning the patient's temperature was normal and he left for England. In the hospital on Quarantine Island it was found that many of the cases of heat stroke occurred between 12 noon and 3 P.M., especially when the air was still or a hot dry wind was blowing; others occurred during the night, from 9 to 12 P.M. Enteric fever, and that of a very severe type, was particularly rife in the early part of the present year at Suakim. Quarantine Island, where so many of the troops were encamped, is built up of partly broken-down coral, many native graves are scattered about, and the foulest odours at all times were exhaled from the mud and decomposing exposed coral on the surrounding foreshore. When it is added that the soil is very unabsorbent, that the ground-water exists at a depth of about two and a half feet from the surface, and that there is no tide, it will be seen that all the conditions are present for the production of putrefaction in any organic matter that may find its way on to or beneath the surface. The temperature of the air in the huts reached, in July, 121° F. The treatment adopted was mostly as follows. The patient was stripped and laid on the canvas bottom of the iron-frame bedstead, with a waterproof sheet beneath him. From twelve to fifteen pounds of ice were placed in a pitcher of water, and a stream of the iced water was poured continuously over his whole person. The length of time during which this cold stream should be applied was determined by the state of the patient's pulse and his temperature. Generally the attainment of a temperature of 101° or 102° was considered satisfactory, and he was then placed in a wet pack for half an hour to an hour, after which he was wrapped in blankets and an ice-bag applied to his head. An enema of iced water was first given, which served the double purpose of clearing the lower bowel and aiding considerably in the reduction of temperature; and then an enema was administered, containing forty grains of quinine, with twenty minims of tincture of digitalis if the heart's action were feeble, and twenty grains of hydrate of chloral if the dyspnœa were marked, together with brandy if considered necessary. The enema was made up to from two to three ounces with iced water. The troops were quartered partly in huts, partly in double-roofed tents, which were further protected by a roofing of matting. The excreta were, where it was possible, conveyed in pails by hand and deposited in the sea; in other cases the usual trenches were dug for latrines. No milk other than condensed was used, and all the water was distilled in ships lying in the harbour. Post mortem all the cases presented the usual pathological changes well known at home. From the above I think it is clear that the enteric fever poison was generated from or in the foul soil under the influence of excessive solar heat, and that it was propagated through the medium of the air."

"Suakim, Jan. 27th, 1886."

WILLS OF MEDICAL MEN.

THE will and codicil of George Charles Julius, M.D., of Claremont House, near Tilford, Surrey, who died on Dec. 1st last, have been proved by Arthur Onslow Julius, the nephew, and Mrs. Katherine Robertson Julius, the executors, the value of the personal estate amounting to over £19,000. The testator bequeaths the silver vase presented to him by his late Majesty King William IV. to his grandson, Herbert Amelius Julius, to be held as a heirloom; various sums of money and his household furniture and effects to his daughter-in-law, Mrs. Katherine Robertson Julius; and one or two other legacies. As to the residue of his real and

Digitized by Google

personal estate, he leaves one moiety upon trust for his said daughter-in-law for life, and then for all her children by his late son Reginald as she shall appoint; and the other moiety upon trust for his daughter, Mrs. Ethel Lambart.

The will of William Benjamin Carpenter, M.D., who died on Nov. 10th last, has been proved by Joseph Estlin Carpenter, the son, the acting executor, the value of the personal estate amounting to over £15,000. The testator gives his interest in a house at Bristol to his son, William Lant; £100 and such of his furniture and effects as she may wish to retain to his wife; and the residue of his real and personal estate upon trust for his wife for life, and then for all his children in equal shares.

The will of Mr. John Christopher Armstrong, late of 14, Park-place, Gravesend, Surgeon, who died on November 4th last, has been proved by Mrs. Annie Armstrong, the widow, and Mr. William Henry Warner, the acting executors, the value of the personal estate amounting to over £11,000. The testator leaves £100 and all his household furniture and effects to his wife; and all his real estate and the residue of his personal estate upon trust for his wife for life or widowhood, and then to divide the same equally between all his children.

The will of John Paton Watt, M.D., late of George Town, British Guiana, who died on August 12th last, was proved in London on the 11th ult. by Henry K. Davson, one of the executors, the value of the personal estate in England amounting to over £3400. The testator gives, devises, and bequeaths the whole of his property, movable and immovable, and wheresoever the same may be situate, to his wife.

The will of John Mason Booth, M.D., late of Sydney, New South Wales, was proved in London on the 4th ult. by Edward Sidgwick. The testator leaves legacies to relatives and others, and the residue of his property to be divided between his two sisters, Jane Mason Booth and Anne Mason Booth.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. James Fletcher, of Woolton-hill, near Liverpool, of Rosehaugh, Ross, and Cromarty, and of Fearn, county Forfar, £500 to the Northern Infirmary, Inverness.—Sir William Rose, K.C.B., late of Leiston Old Abbey, Leiston, Suffolk, and of 39, Bruton-street, £50 each to the Westminster Hospital and the East Suffolk Hospital, payable on the death of his wife.—Mrs. Marian Francis Dobson, of Lyde House, Sion-hill, Bath, £220 to the Convalescent Home, Combe Down; £200 to the National Hospital for the Paralysed and Epileptic, Queen's-square, Bloomsbury; £110 to the United Hospital, Bath; and £100 each to the Mineral Water Hospital, Bath, the Hospital for Incurables, Putney, and the Hospital for Sick Children, Great Ormond-street.—Mrs. Elizabeth Blagden, of Long Clawson, Leicestershire, £100 to the General Hospital, Nottingham.—Right Hon. Louisa Lady Rolle, late of Bicton, Devon, £100 each to the Exeter Lying-in Charity, the West of England Eye Infirmary, Exeter, and the Exeter Dispensary.—The Rev. Thomas Garden Carter, Hon. Canon of Canterbury Cathedral, late of Linton, Kent, £100 to the West Kent General Hospital, Maidstone.—Mrs. Adelaide Mildred Livins, late of 32, Hampton-park, Redland, Bristol, £100 to the Bristol Infirmary, and £50 each to the General Hospital, Bristol, the Sick Children's Hospital, and the Redland Dispensary.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Stroud Urban District.—Mr. Thomas Partridge gives the mortality for this district at the rate of 19·6 per 1000 during 1885, a rate which he very properly regards as too high for a district like Stroud, which has considerable natural advantages. Steps are being taken to improve the water-supply, but it is quite evident that the abolition of wells on private premises should also be one of the early pieces of work for the sanitary authority to undertake. The state of the water from some of the wells also points to the fact that the soil from which it is drawn is subject to considerable soakage of filth, and it is also clear that some remedial measures, by way of improved drainage or otherwise, are necessary to prevent this process of soil-pollution from going on. Steady sanitary work is in progress, and the record of it includes a number of instances in which the water-supply has been improved, although no wells have been closed during the year.

Bisley Urban District.—This district is under the same health officer as Stroud, and in 1885 it had a death-rate of 17·1 per 1000. Measles are stated to have been very prevalent, and it is added, that by closing the schools for a fortnight the disease was so materially checked that teaching could be resumed. Improvement of the water-supply has been carried out, the dairies have been carefully inspected, and samples of food and drugs have been submitted for analysis.

West Ham Urban District.—Dr. Drake reports that during 1885 the very heavy infantile mortality which he has before had occasion to record still continues, and this in spite of the existing sanitary administration of the district. Small-pox caused 563 deaths, but of these 69 were cases imported from other parishes, an importation doubtless representing several hundred cases. Although 114 of these deaths occurred amongst persons who at one time or another had been vaccinated, it appears that it has been impossible to find a death in the case of any persons who had been properly revaccinated within a reasonable period. Dr. Drake, in referring to the proposed reopening of the Plaistow Small-pox Hospital, stated that if this were carried out the buildings would have to be enlarged, and, having regard to past experience, he has advised his sanitary authority to make strong representations in opposition to the proposal. The annual death-rate was 21 per 1000 living, this rate being 1 per 1000 in excess of that for the previous year.

Teignmouth Urban District.—Occasion is taken of the completion of a new system of sewerage for this district to embody in a special report a description of the town and neighbourhood with reference to drainage. Complete separation has been effected between the channels for the conveyance of sewage and those for carrying away storm water and surface-water from the streets, the latter waters reaching the Tame brook by means of the former pipe sewers. The new sewers reach a large retaining tank on the shore of the estuary, from which an iron pipe sewer has been constructed to low-water mark, the contents only entering the estuary while the tide is flowing out. The principal sewers are provided with Field's automatic flush tanks, and ventilation is carried out by street gratings and upright shafts. Mr. Lake does not refer to any system of house drainage, but it is to be hoped that the sanitary authority will not allow their excellent work in the matter of sewerage to suffer any discredit by means of the faulty systems of house drainage, and the lack of through-ventilation of every such drain, which are so often left to take care of themselves on the completion of sewerage schemes.

Hereford Combined Districts.—Dr. H. S. Sandford is one of the medical officers for combined sanitary districts who issues his reports at a time when they are really useful—namely, soon after the expiration of the period to which they relate. The information they contain for 1885 is largely statistical and of local value, but we could wish that, in addition to mere records of death and sickness, there were more information as to the general improvements effected year by year as regards the more important circumstances under which the people in each district live. The deaths and the existing diseases are fully dealt with, and in some districts certain advice as to the future is given apart from the prevalence of sickness—for example, as to an improved water-supply at Ledbury; but the non-resident reader would gladly learn more as to sanitary provision which influence health in several portions of the area concerned. Tabulated and other material shows that nuisance removal is cared for, and we learn that in one respect at least—namely, in the important matter of water-supply—the city of Hereford has all that health can need.

Torquay Urban District.—Mr. Karkeek offers a most satisfactory report on Torquay, and he observes that the results attained are mainly due to the incessant care recently taken as to the sanitary state of houses and the isolation of the infectious sick. Torquay has spent £80,000 on its sewerage system, £30,000 on water-supply, £3600 on hospital provision, and, together with other matters, a total sum of £133,000 has been spent in ten years in sanitary works of the first importance. This expenditure will, we believe, soon be found to be remunerative, and we have no hesitation

Digitized by Google

in saying that the proportion of interest and capital which must annually be set aside to cover it will be largely provided by those who will seek a health-resort at a spot where health considerations are prominently held in view. In few districts are the residences, the villas, and other houses subjected to such careful inspection as is carried out under Mr. Karkeek's administration of the health office. Deducting deaths of outsiders, the death-rate for 1885 was 13·9 per 1000, and there was only a single death from either of the continued fevers. The sanatorium received thirty-three patients, eleven of them being persons of independent means or belonging to the professional and commercial classes. In short, the value of efficient isolation is becoming more and more appreciated.

Carlisle Urban District.—The death-rate for this city was 20·3 per 1000 in 1885; and the only infectious disease that was fatally prevalent was measles, which caused 22 deaths. Typhus was seen in June, but it was at once stamped out by means of isolation in hospital and efficient disinfection. Typhoid fever and diarrhœa have only been slightly prevalent, and Mr. Brown, referring in some detail to the causes of these diseases, points out that the local system of midden closets which has twice been so strongly condemned by medical inspectors of the Local Government Board, is being gradually abolished or modified so as to be less injurious to health. The water-supply is abundant and good, the model bye-laws as to lodging-houses are being carried out, the slaughterhouses are being carefully looked after, and infectious diseases are promptly dealt with.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6083 births and 4024 deaths were registered during the week ending February 13th. The annual death-rate in these towns, which had been equal to 22·1 and 22·2 per 1000 in the preceding two weeks, further rose last week to 23·1. During the first six weeks of the current quarter the death-rate in these towns averaged 22·7 per 1000, and was 2·2 below the mean rate in the corresponding periods of the ten years 1876–85. The lowest rates in these towns last week were 14·7 in Huddersfield, 15·3 in Leicester, 15·7 in Bradford, and 18·3 in Hull. The rates in the other towns ranged upwards to 25·5 in Norwich, 29·0 in Cardiff, 29·1 in Manchester, and 30·9 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 360 and 376 in the previous two weeks, further rose last week to 405; they included 188 from whooping-cough, 67 from measles, 46 from diarrhœa, 43 from "fever" (principally enteric), 30 from scarlet fever, 28 from diphtheria, and 3 from small-pox. No death from any of these zymotic diseases was recorded last week in Halifax; whereas they caused the highest death-rates in Plymouth, Portsmouth, and Blackburn. The greatest mortality from whooping-cough occurred in Salford, Brighton, and Portsmouth; from measles in Portsmouth, Nottingham, Plymouth, and Blackburn; from scarlet fever in Birkenhead and Leicester; and from "fever" in Norwich, Plymouth, and Blackburn. The 28 deaths from diphtheria included 18 in London, 2 in Birmingham, and 2 in Huddersfield. Small-pox caused but 1 death among the residents of London and its outer ring, and 3 in Liverpool, but not one in any of the twenty-six other large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had declined in the preceding thirteen weeks from 90 to 18, had further fallen to 11 on Saturday last, only 1 case having been admitted during the week. The Highgate Small-pox Hospital contained 3 patients on Saturday last, no case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 477, 478, and 479 in the preceding three weeks, further rose last week to 584, but were 21 below the corrected weekly average, a noteworty fact, having regard to the low temperature that has prevailed in recent weeks. The causes of 94, or 23 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Newcastle-upon-Tyne, Leeds, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Hull, Bradford, Oldham, and Leicester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the preceding four weeks from 23·9 to 21·3, rose again to 24·5 in the week ending February 13th, and exceeded by 1·4 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 11·5 in Perth and 13·3 in Leith, to 27·1 in Aberdeen and 29·7 in Glasgow. The 606 deaths in the eight towns showed an increase of 79 upon the number in the preceding week, and exceeded the number in any previous week of this year; they included 17 which were referred to whooping-cough, 16 to diarrhœa, 9 to "fever" (typhus, enteric, or simple), 6 to scarlet fever, 5 to diphtheria, and not one either to small-pox or measles. Thus, 53 deaths resulted from these principal zymotic diseases, against but 37 and 32 in the previous two weeks. These 53 deaths were equal to an annual rate of 2·1 per 1000, which was 0·2 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 13 and 9 in the previous two weeks, rose last week to 17, of which 14 occurred in Glasgow and 2 in Paisley. The 16 deaths attributed to diarrhœa showed a considerable increase upon the numbers in recent weeks, and also exceeded the number in the corresponding week of last year. The 9 deaths referred to "fever" also showed an increase upon recent weekly numbers, and included 2 in Glasgow, 2 in Edinburgh, and 2 in Greenock. The 6 fatal cases of scarlet fever and the 5 of diphtheria corresponded with the numbers in the previous week; 4 of the deaths from diphtheria occurred in Glasgow, and the deaths from diphtheria included 2 in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 156 and 135 in the preceding two weeks, rose again last week to 144, but were 8 below the number in the corresponding week of last year. The causes of 78, or nearly 13 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 29·6, 31·9 and 33·7 per 1000 in the preceding three weeks, further rose to 38·6 in the week ending Feb. 13th. During the first six weeks of the current quarter the death-rate in the city averaged no less than 32·7 per 1000; the mean rate during the same period did not exceed 23·0 in London and 18·5 in Edinburgh. The 261 deaths in Dublin last week showed a further increase of 33 upon recent weekly numbers, and included 26 which were referred to the principal zymotic diseases, corresponding with the number in the preceding week; 14 resulted from "fever" (typhus, enteric, or simple), 10 from whooping-cough, 1 from scarlet fever, 1 from diarrhœa, and not one either from small-pox, measles, or diphtheria. These 26 deaths were equal to an annual rate of 3·8 per 1000, the rate from the same diseases last week did not exceed 2·8 in London and 1·0 in Edinburgh. The fatal cases of whooping-cough, which had ranged from 13 to 19 in the previous four weeks, declined last week to 10. The deaths referred to "fever" rose last week to 14, from 1 and 6 in the previous two weeks, and exceeded the number returned in any week since the end of 1884. Seven inquest cases and 7 deaths from violence were registered; and as many as 97, or more than a third of the deaths, were recorded in public institutions. The deaths both of infants and of elderly persons showed an increase upon recent weekly numbers. The causes of 39, or nearly 15 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

INDIA OFFICE.—The Queen has approved of the following promotions amongst others made by the Governments in India:—Surgeon-Major George Dalziel Riddell, of the Madras Medical Establishment, to be Brigade Surgeon; Surgeon-Major George Yeates Hunter, of the Bombay Medical Establishment, to be Brigade Surgeon.

ADMIRALTY.—The following appointments have been made:—Fleet Surgeon Walter F. C. Bartlett, to the *Castor*: Fleet Surgeon Robert H. More, to the *Impregnable*: and Mr. William Clibborn to be Surgeon and Agent at Bridport.

ARTILLERY VOLUNTEERS.—2nd Lancashire: Surgeon

Digitized by Google

Martin G. B. Oxley, M.D., is granted the honorary rank of Surgeon-Major.

RIFLE VOLUNTEERS.—1st Tower Hamlets (the Tower Hamlets Rifle Volunteer Brigade): Surgeon and Honorary Surgeon-Major John Hayball Paul, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement. Acting Surgeon Octavius Mark White to be Surgeon.

"Audi alteram partem."

MORTALITY FROM INFECTIOUS DISEASES IN THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—Dr. Ogle's important and valuable statistics on Mortality in the Medical Profession, recently read before the Royal Medical and Chirurgical Society, raise the following interesting question: What degree of immunity is acquired by medical men against the virus of infectious diseases by frequent and in some cases constant exposure? That some immunity is conferred is clearly proved by the statistics now before us; for although by virtue of our occupation we are almost daily exposed to the germs of these diseases in the sick room, in addition to being subjected to the same dangers of infection as the general public, yet the deaths per million in the profession from scarlet fever, diphtheria, and typhus are only increased 3·6, 4·2 and 2·07, respectively, above the average mortality from the same diseases in men taken generally. How can we explain this? The general public offer an explanation by averring that either medicine is taken as a prophylactic or that a special providence protects the doctor. Were this so the mortality from these diseases should be almost *nil*. Bretonneau, in his fifth memoir on Diphtheria,[1] remarks "that habit, which subdues the wild animals, also mitigates the various kinds of morbid poisons. By penetrating into our economy the morbid poisons multiply there, which circumstance, however, does not prevent the amount of each dose of the virus successively absorbed from exercising a weakening influence over its operation, so that at the period of an epidemic the physicians who have a large practice, running from one patient to another and absorbing only fractional portions of virus, succeed in attaining an immunity which is often observed and generally ill-understood." Trousseau, however, thought immunity from acclimatisation and habitual exposure to be more apparent than real, and in support of this mentions the fact that in the Crimea the mortality from typhus was greater amongst the medical officers than the soldiers. Dr. Ogle's statistics show vastly different results when the whole of the profession is considered. It would, however, be interesting to know the mortality of medical officers in our fever and small-pox hospitals. It is highly probable that much depends upon the state of health at the time of coming into contact with the organism. If the body be in a depressed condition, as is often the case in our hospitals, and rich in the pabulum necessary for the organism's existence, and should also this particular organism have not been met with for a considerable time, in all probability nothing short of immunity produced by a previous attack is likely to serve as a protective, and this we know will not always avail. Two infectious diseases appearing at the same time in the same subject usually modify each other. One disease seems to offer protection from another, as in the case of cow-pox and small-pox. Then, may not the frequent inhalation and absorption to some extent by the mucous membrane of the mouth and respiratory passages of various organisms, which probably are more or less generically related, serve to protect us from an actual attack of the disease they respectively produce? The pathological change in the blood and tissues necessary to secure this immunity, whether it be due to the exhaustion of some chemical compound necessary for the existence and multiplication of the organism, or, as Klebs believes, the production of some substance which acts inimically to another immigration of the same organism, is difficult to decide. One thing is certain, however, that, short of an attack of the disease, this change may take place insensibly and without producing any great constitutional disturbance. During epidemics we all have observed abortive cases of the disease under observation bearing ill-defined symptoms and producing but little disturbance of the general health, yet apparently giving an immunity hereafter. Bretonneau mentions the fact of pregnant women attending upon small-pox patients having given birth to children suffering with the disease without having suffered any constitutional symptoms themselves, thus proving that a considerable quantity of poison may be received into the system without causing any appreciable untoward bodily effect.

Dr. Ogle's statistics prove what must be satisfactory to members of the profession, that a considerable degree of immunity is conferred upon us by attendance upon infectious diseases; for were this not so, all things being equal, we should have seen recorded a much higher mortality from these maladies. I am, Sir, yours truly,

Stanley, Durham, Feb. 9th, 1886. ALFRED MANTLE, M.D.

"THE CONNEXION BETWEEN THE PAROTID GLANDS AND THE GENERATIVE ORGANS."

To the Editor of THE LANCET.

SIR,—The correspondence originated by Mr. Paget in THE LANCET of January 9th, on the Relation of the Parotid to the Generative Organs, however important and instructive, has not so far either negatively or affirmatively ripened into a settlement of the question. That desirable result can only be attained by the accumulation of reliable evidence and extended observation, and, as I have some information on the subject to communicate, I may be pardoned for taking part in the discussion. In the first place, the teaching of experience has convinced me of the intimate relationship existing between the parotid and the organs of generation, so often manifested in the mutual derangement of functions and of normal health. The weight of evidence adduced by your correspondents has only added to the strength of my convictions; and I am willing to adopt as my own the dictum of Professor Möricke, as quoted by Mr. Tayler—viz., that from "the well-known relation existing between the testicle and the parotid we may infer that the same exists between the ovary and the parotid." My observations shall be directed towards proving the correctness of the inference, and I shall commence by giving the history of one remarkable case.

Mrs. M——, at present aged forty-three years, consulted me in the month of June, 1874, before the birth of her second child, on account of a troublesome enlargement of the left parotid gland, which destroyed the symmetrical appearance of her face, and was otherwise a cause of discomfort. She was then about six months pregnant. The tumour was as large as a small-sized orange, of oval shape, and about three inches in length by two in breadth. She informed me that it had begun to enlarge soon after the commencement of pregnancy, and had continued to grow week by week up till that time. She had not suffered in this way with her first child, which was born in the country. Regarding the tumour as of idiopathic origin, I prescribed iodide and bromide of potassium and the external application of iodine liniment, but without any effect; the tumour slowly increased till the period of her confinement, when it immediately began to collapse, and almost altogether disappeared within the succeeding month, leaving, however, a sensible permanent enlargement. During the period of growth she had not suffered from pain nor increased salivation; there was no tendency to redness or suppuration, and she was quite free from the morning sickness or reflex vomiting of pregnancy. I had wellnigh forgotten the circumstance until the reappearance of the lady some two years later, when she called to request my attendance at her third confinement; she then had an enlargement of the left parotid similar in every respect to that which accompanied her previous pregnancy. Mrs. M—— informed me that soon after she was conscious of her condition the gland began to enlarge as before, and its increase was concurrent with the advance of gestation. Just as before, the tumour rapidly disappeared after confinement, and in the succeeding pregnancies she has learned to

Digitized by Google

recognise this strange phenomenon as one of the first indications of her gravid condition. This incident has now occurred under my observation for the sixth time in succession, the last child born being now nearly twelve months old. The subject of this remark is of spare habit, tall and thin, and sallow. She has no family history of any importance, but of the children born to her there appears to be in several a dyscrasia of the bony structures, as an ordinary fall is liable to produce a fracture of the bones of the arms. I have had to treat one of her boys three times for fracture of the forearm, another twice, and a third for a fracture and a dislocation of the shoulder.

To what causation, then, are we to attribute this unusual manifestation? The explanation is difficult, except on the grounds of a distinct relation between the generative organs and the gland, and that, like the reflex vomiting, the neuralgic toothache, and the disorders of nutrition that so often accompany the gravid condition, it is also due to sympathetic causes and to the discharge upon the parotid of surplus nervous energy, originating in ovarian excitement. In this particular case the gland appeared to act as a diverticulum, as neither morning sickness nor dental suffering was complained of. We cannot explain why it is that in one case the dental branches of the fifth suffer, or in another why the vagus is implicated in the process of utero-gestation, while we admit the causal relation. Neither can it be urged that these developments are due to accident or mere coincidence—the marked antecedence and sequence in each case forbid such a conclusion; nor yet to sepsis, the other explanation offered by Mr. Tayler in the absence of wound or abrasion of any kind.—I am, Sir, yours truly,

Belfast, Feb. 14th, 1886. ALEX. HARKIN, M.D., F.R.C.S.

SOLID TUMOURS OF THE MESENTERY.

To the Editor of THE LANCET.

SIR,—In the interesting letter of Dr. Hamerton, published in your number of Feb. 6th, pp. 278-9, he alludes to a case where I removed a solid mesenteric tumour of the size of an adult head as the only successful one among eight recorded cases. This becomes additionally interesting as I have at last obtained a report of the microscopic examination of the tumour. Mr. Arthur Jackson of Sheffield writes to me: "I had it examined by two competent microscopists, independently of each other, and it was reported to be a rapidly recurring spindle-celled sarcoma." As the operation was done in June, 1882, and the patient has had no abdominal trouble since, but has enjoyed very fair health, we may hope that the fear of recurrence has passed away. When my "Diagnosis and Surgical Treatment of Abdominal Tumours," referred to by Dr. Hamerton, was published, and particulars of the case and operation were given at pp. 201-5, I had not received any report as to the structure of the tumour.

I am, Sir, yours truly,

Feb. 16th, 1886. T. SPENCER WELLS.

"MR. HORSLEY'S CRITICISM OF PROFESSOR SCHIFF."

To the Editor of THE LANCET.

SIR,—In the remarks I made on Mr. Horsley nothing could have been further from my intention than to overstep the limits of fair criticism. Misled by the imperfect abstract of his lectures, I believed, as did also Professor Schiff, that Professor Horsley's criticism rested on the supposed impossibility of the experiment in question (cutting the posterior cords without injuring the motor tract). From Professor Horsley's letter I see that this belief was erroneous, and that my criticism was beside the point.

Having left Geneva, I fear I shall not have an opportunity of returning to the subject. However, I sent Professor Horsley's letter to Schiff; and in his reply are words to the following effect: "Now I understand what Mr. Horsley means by the motor tract. He believes that the posterior part of the lateral columns near the posterior horns of the grey substance is motor. This is a very general opinion, against which I shall publish a series of experiments in a physiological journal. I shall send you my paper when it is printed."

Touching Professor Horsley's explanation of the position of the foot as being due to paralysis, I would simply remark that in the experiments reported by me no evidence of paralysis was discoverable; while a cause capable of accounting for the phenomenon—loss of tactile sensibility—was proved to be present. I am, Sir, your obedient servant,

Davos Platz, Feb. 13th, 1886. WILLIAM R. HUGGARD.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—I tender you my sincere thanks for the interest and able support you are giving towards forwarding the object of the above Association; and I think it the duty of every Member to encourage and assist the promoters in carrying out the purport of the petition. The "sop" which Mr. Hutchinson proposed to the Council is hardly good enough to be swallowed by the majority of the Members, who, after all, are undoubtedly the back-bone, financially, of the College, and ought therefore to insist on their rights being given them, whereby they may exercise a supervision over what is really their own. This "kick-out" into the cold, so soon as our fees have been safely secured in the coffers of the College, is, to say the least of it, ungrateful and mean, and the only wonder is that the thing has been allowed to go on for so long. I would ask every Member to read your able article in the last issue of THE LANCET, and then proclaim aloud their indignation against the individuals who would still rob them, by offering a "mess of pottage" for their "birth-right." I am, Sir, yours faithfully,

Manchester, Feb. 13th, 1886. HENRY CARTMEL, M.R.C.S.

MANCHESTER.

(From our own Correspondent.)

CENTRAL MEDICAL SOCIETY.

AT the time the new Central Medical Society was formed, one of the chief reasons advanced for its establishment was the fact that the reading-room and meeting-rooms of the Medical Society at Owens College were situate too far from the centre of the city. Recently the committee of the College Medical Society have endeavoured to remove this ground of complaint by engaging central rooms at the Literary and Philosophical Society, where the journals and papers can be seen and books obtained from the library by telephone; but during the three months this has been in operation only three members have availed themselves of this means of obtaining books, which looks as though the members generally do not consider the distance too far to go themselves to the library. Further, the committee have endeavoured to obtain the opinion of members as to the desirability of altering the time and place of the meetings; about one-third appeared in favour of afternoon meetings, so an experiment is to be tried by holding a few at 4.30 P.M. at the central room.

THE CHAIR OF PHYSIOLOGY.

The post of Professor of Physiology has at last been filled by the appointment of Professor Stirling, who comes from Aberdeen with very high credentials. It is unfortunate that the greater part of the winter session has passed away without there being a responsible teacher at the head of this important branch of medical studies; but it appears that, in response to the advertisement issued on the resignation of Dr. Gamgee, no candidate of sufficient repute was forthcoming, and overtures were then made to Professor Stirling, with a successful result. The Victoria University Extension lectures are apparently meeting with much success. It was stated at the first, delivered by Professor Marshall at Withington, that over 200 subscribers had been obtained for the course of lectures on Natural History.

THE LOCAL CHARITIES.

The annual meetings have been held of various local hospitals—the Clinical, the Children's, St. Mary's, and the Eye Hospital. From them all comes the same cry—expenditure exceeding income, and an appeal for increased support. The committee of St. Mary's Hospital again bring forward

Digitized by Google

the question of obtaining a new hospital. This, the only maternity charity we have, has increased greatly of late years, and the hospital, antiquated in structure, is but ill adapted for the demands made upon it. The meeting of the Eye Hospital was a red-letter day in the annals of the institution, it being also the opening day of the new and handsome building recently completed in Oxford-road. It has been in use for some little time, but the formal ceremony took place on Monday last, when the Mayor of Manchester (Mr Alderman Goldschmidt), in the presence of a large and influential gathering, declared the new building open. Mr. Goldschmidt is chairman of the Board of Management, and it is not too much to say that it is in great measure due to his indefatigable interest and work on behalf of this charity that it finds itself to-day located in one of the best-equipped buildings for its purpose which exist in the country. Accommodation is provided for 100 in-patients and for a daily attendance of 400 out-patients. Sunday last was our Hospital Sunday, but it is too soon to say what the results are compared with last year. It is hoped that this year's Hospital Sunday Fund will show a considerable increase. The hospitals which share in these collections are said to have relieved no less than 125,000 persons during the past year. One is almost tempted to ask if this be in all respects a thing to be proud of, though in fairness it should be stated that this large number are not all supplied by Manchester, for the surrounding towns send a goodly contingent—perhaps more than they ought, seeing that most of these have local hospitals of their own.

MEDICO-LEGAL CASES.

At the last assizes there were one or two cases of some medical interest. In one a charge was brought by a young woman of a criminal assault against a dentist whilst under the influence of nitrous oxide gas administered by him previous to extracting a tooth. The evidence in support of the charge was very weak and the jury were discharged without finding a verdict. The moral is the old one, never to administer anæsthetics to a female patient without the presence of a third person. At the same assize a woman, the widow of a boiler-maker, was awarded £150 damages for the loss of her husband from hydrophobia from the bite of a dog. A stonemason employed upon the new buildings now in progress at Owens College obtained £200 from the tramway company for the loss of his leg, the result of an injury received through being run over by one of their cars.

The outbreak of typhus fever in Gorton, alluded to on a previous occasion, has been the means of causing the death of two nurses at the Withington Hospital, whither some of the patients suffering from that disease had been removed.

Manchester, Feb. 16th.

LIVERPOOL.

(From our own Correspondent.)

THE LOCAL HOSPITALS AND THEIR FINANCES.

THE annual meetings of all the hospitals have now been held, and at all the same story is told: greatly reduced incomes, but no reduction of expenditure,—rather the reverse. The Royal Infirmary is £6000 in debt; both the Northern and Royal Southern Hospitals have each a deficit of £2000; while the other hospitals are all more or less hampered with debt. Great efforts will have to be made to free these most useful charities from embarrassment, as well as to place them in a more stable position by increasing the subscription list and otherwise augmenting the income.

THE LATE RECORDER OF LIVERPOOL

The news of Mr. John Bridge Aspinall's death was received here with much sorrow, the learned gentleman having been extremely popular with all classes. To all medical witnesses who appeared in his courts he was extremely courteous and affable, showing every regard to their convenience so far as he was able.

MEDICAL WITNESSES AT THE ASSIZES.

Whether the Grand Jury should or should not be perpetuated may be questioned; but that there should be proper accomodation for all witnesses, including medical witnesses, while waiting their turn, cannot be doubted. The arrangements at our local assize and sessions courts are abominable. All witnesses waiting to go before the Grand Jury are obliged to stand at the top of a flight of stairs, medical witnesses, solicitors, occasionally ladies, all being mixed up with the very lowest specimens of humanity to be found in this or any other city. One such experience may be instructive, but repetition makes it wearisome, and there can be no justification in perpetuating such a miserable arrangement.

MR. JUSTICE DAY ON CORPORAL PUNISHMENT.

The Criminal Law Amendment Bill has had the effect of bringing to justice many who, under the old law, would have escaped. In consequence of this, the number of charges of indecent outrage has greatly increased at the present assizes. In his charge to the Grand Jury Mr. Justice Day remarked upon the defective state of the law as regards these crimes. While in cases of violent assault and robbery of the smallest coin he could award corporal punishment, for the outrages on females he could only award penal servitude for long periods, which was only demoralising to the prisoners and expensive to the country. He regretted that the opinion of the country and sentiments of the public were so strongly opposed to corporal punishment.

THE CITY HOSPITAL FOR INFECTIOUS DISEASES.

The Hospital Sub-Committee of the Health Committee have passed a resolution that Dr. Hope shall temporarily reside at the Parkhill Hospital whenever in the opinion of the medical officer of health it is desirable that he should do so, and that during any period of such temporary residence he shall receive an allowance at the rate of £2 per week.

Liverpool, Feb. 15th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE INFIRMARY.

THE annual court of governors was held last week, when some interesting facts were given as to the progress and work of this great institution. The infirmary, with its late addition, has now proper accommodation for 270 patients. On the whole, the hospital has been in a healthy condition during the year; but in reference to the outbreak of scarlet fever in July last, it was stated that one of the resident surgical assistants contracted the disease, and two nurses, one laundress, and seven patients became affected with the malady in succession. It is believed that the surgical assistant became infected while attending an out-patient in the casual department. The portion of the house where these cases occurred was at once emptied and thoroughly disinfected, and so the affection was stamped out. The number of in-patients treated during the year had been 2846, being 268 more than in the previous year. The greatest number in the house in one day had been 271. The whole number of out-patients received during the year had been 4932, being an increase of nearly 1000 on the previous year. The number of casuals treated during the year had been very large, amounting in all to 27,811, nearly 5000 more than in the previous year. Many other interesting facts and figures were given, which I must hold over for future consideration.

A CHEMIST'S MISTAKE.

At the South Shields County Court last week William Morris and his wife sued Messrs. Mason and Co., chemists, of South Shields, for damages sustained by them in consequence of injuries to the female plaintiff through the defendants having negligently supplied her with tincture of iron instead of tincture of rhubarb, for which she asked. For the defence it was contended that the plaintiff was supplied with what she had asked for. The judgment, however, was given for the plaintiff for £5 and costs.

APOPLEXY OR DRUNKENNESS?

At a late meeting of the Middlesbrough police magistrates an ex-inspector of police was charged with being found drunk and helpless on a doorstep by two police constables. The defendant tried to make out that it was a mistake of diagnosis on the part of the constables, and stated that he was suffering from apoplexy at the time; and proceeded

Digitized by Google

to give the Bench a very elaborate account of the differential symptoms observed in the two affections. The Bench, however, while giving him credti for much special medical acumen, fined him 10s., including costs, or seven days' imprisonment.

NORTHERN CORONERS ON UNQUALIFIED PRACTICE.

The Coroner of Newcastle, at an inquest held last week, made some strong remarks upon the subject of unqualified practitioners in the case of a child that had died suddenly after treatment by an unqualified practitioner, who, it appears, had also given the mother of the child a death certificate. The coroner told her "that it was a pity that she had not sought a properly qualified practitioner, because if she had done so no inquest would have been necessary." Alluding to the so-called "dispensaries," "there were," he said, "too many in the city, which in many instances were conducted by those who were anything but duly qualified. He would forward the certificate, which had been given to the proper authorities to deal with as they thought fit." At a late inquest at Jarrow the matter was also referred to by the coroner of that district; a child had died suddenly after having been attended by an unqualified practitioner. It was shown that the child had died of bronchitis, and might have recovered if proper means had been used at an earlier stage of the disease. The coroner, addressing the unqualified practitioner, said that this practice must be stopped. He thought it was a very hard case, especially in these bad times, that men had to be called away from their business to serve as jurymen, and that all the expense of an inquest might have been saved had the mother called in a registered practitioner. Another serious matter was the fact that the letters "M.D." came after his name on a note which he had given the mother supposed to have been the certificate of death. On the unqualified practitioner promising that it would not occur again, the jury returned a verdict of "Death from natural causes." Our coroners in the north are evidently giving more attention to the injury perpetrated on the public by illegal practitioners, to say nothing of the injustice done to the profession by many of these so-called "dispensaries."

EDINBURGH.

(From our own Correspondent.)

THE LATE DR ANGUS MACDONALD.

THE Edinburgh Medical School has suffered a severe loss in the early death of Dr. Angus Macdonald. The deceased gentleman was still in the prime of middle life; and it might well have been anticipated that his useful and successful career would have been greatly prolonged. Until the last few days he was in the full exercise of his teaching functions at the Royal College of Surgeons, and closely engaged in the arduous exertions of a very extensive private practice, in addition to his duties as physician to the Royal Infirmary and to the Maternity Hospital. His death has caused a deep and widespread feeling of regret in Edinburgh and throughout Scotland, not only amongst the members of his own profession, very many of whom looked to him for advice and aid in cases of difficulty, but also amongst the public at large, by whom he was well known and greatly respected.

VACCINIA AND VARIOLA.

At the last meeting of the Edinburgh Royal Society, Dr. J. B. Buist, Lecturer on Vaccination for the Local Government Board, presented a monograph upon the "Life History of the Micro-organisms associated with Variola and Vaccinia." In it are detailed the results of a long series of experiments, occupying nearly a year, which he carried out in the surgical laboratory of the University under the charge, of Professor Chiene. Dr. Buist, taking advantage of the most recent bacteriological methods, has succeeded in procuring cultivations of organisms from both diseases, and has made a series of interesting observations with each. He finds that the ape is susceptible to an artificially induced variola and vaccinia identical in all respects with the same conditions in the human subject. His practical observations on the difference between clear and opaque vaccine lymph are of great interest and importance. In the latter he describes an acid reaction, whilst in clear lymph the reaction is alkaline; and he attributes the opacity of lymph to the development in it of a microbe. His paper was stated to be only of a preliminary nature, and the further outcome of his observations, bacteriological and clinical, will be looked for with great interest.

ABERDEEN.

(From our own Correspondent.)

APPOINTMENT FOR DR. SIMPSON.

DR. SIMPSON has been appointed medical officer of health for Calcutta. This is an important and valuable appointment, and he is to be congratulated on receiving this well-merited recognition of the excellent work he has done in sanitary science during the past five years. Since he came to Aberdeen the death-rate has gradually decreased, and last year it reached the lowest figure ever recorded for the city.

EPIDEMIC OF DIPHTHERIA.

Diphtheria made its appearance in Aberdeen some six or eight weeks ago, and has gradually spread until now it may be said to be epidemic. The proportion of fatal cases is alarmingly large, and unfortunately the sanitary officials have so far failed to trace the cause of the outbreak, which is chiefly confined to the Rosemount and Mile-end districts of the town. It was here also that scarlet fever was so prevalent at the end of last year, and it is possible that the deficient water-supply may have some connexion with the rapid spread of zymotic diseases in this part of the town.

ABERDEEN GENERAL DISPENSARY.

Two vacancies are about to occur in the medical staff of the Aberdeen General Dispensary by the departure of Dr. Frank Ogston for New Zealand and by the resignation of Dr. MacGregor. A keen canvass for the appointments is being carried on. Rumour has it that Dr. Edmond and Dr. Gordon are to be the successful candidates.

(The name of the lecturer in University College who is a candidate for the chair of Physiology is Dr. MacWilliam, not Dr. William, as stated in my last communication.)

PTOMAINES AND THE MICROBE THEORY.

IN his enthusiasm, Professor Peter, in his discourse at the Academy of Medicine (which was noticed in my letter of last week) on the part played by ptomaines and microbes in the pathogeny of disease, almost left his hearers under the impression that he meant to say that all human ailments resulted from auto-infection by toxic substances generated in the system, thus ignoring, whether he did so intentionally or not, the pathogeny of specific or infectious diseases. Even M. Gautier, for whom Professor Peter stood up as champion, repudiated such an idea in the following terms, at the meeting of the Academy last week:—"I do not think that one can deduce from my researches the consequence of the spontaneity of disease in a great number of cases in which we see it transmitted by contagion, direct or indirect, from an organism in a pathological state to a healthy one in the full performance of normal physiological functions; still less would this spontaneity be admitted in the cases where it is certain that the contagium is one of those cellular ferments which are now so well known, thanks to the admirable works of M. Pasteur, the constitution, organisation, and evolution, ferment by which appears, and without which a specific malady is not produced; for instance, infectious charbon, rouget of the pig, cholera of fowls, leprosy, small-pox, scarlatina, syphilis, &c., in which one must admit the action of a virulent specific agent, and consequently organised, although in these cases the agent has not always been isolated." Moreover, the author added that while a specific affection cannot be produced spontaneously without the influence of some contagium intro-

Digitized by Google

duced into the organism from the exterior, there exists a great number of maladies the cause of which is in ourselves. It will therefore be absurd and dangerous, pushing to the extreme the consequences of the great discovery of the organised and living nature of the contagious elements of epidemic maladies, to believe that one must always admit the introduction of microbes in the animal economy when a disease breaks out. M. Pasteur himself never intended that this should be supposed. Gout, arthritism and its numerous manifestations, acute rheumatism and the acid dyscrasias, anæmia with its accidents and varieties, diabetes and the other diseases resulting from incomplete oxidations, famine fever and the other maladies caused by low nutrition, pneumonia and pleurisy, traumatic fever, with contusions without any wound of the skin, finally all the numerous maladies which result from an affection of the nervous system, and which, through its medium, affects the sensibility, mobility, nutrition, and intelligence, are diseases, febrile or not, the primary causes of which are in us. It is in this sense that the subject must be studied. Thus it may be seen that, while approving of Professor Peter's theory, M. Gautier did justice to M. Pasteur.

DEATH OF DR. MAC CARTHY.

Dr. MacCarthy, the oldest British medical practitioner in Paris, died on Wednesday, the 10th inst., in the seventieth year of his age. For some months past the deceased gentleman had been in failing health, and at the beginning of last week he was seized with cerebral hæmorrhage, which resulted in hemiplegia, from which he never rallied. Dr. MacCarthy was an Irishman by birth, and came over to Paris as a lad. He studied medicine in this country, and took his degree at the Faculty of Paris in 1844. Some twenty years ago, with Sir Joseph Olliffe and Dr. Campbell, Dr. MacCarthy had the leading English practice in Paris. He also had a very good French connexion, and was much esteemed by all who knew him.

Paris, Feb. 16th.

BERLIN.

(From our own Correspondent.)

BOARD OF HEALTH IN JAPAN.

IN Japan a Board of Health has been created, formed on the pattern of the board of the same name of the German Imperial Government. The management of the Japan board is in the hands of Dr. Mansanori Ogata, Professor of Hygiene in Tokio, who studied for several years in Munich, Leipsic, and Berlin, and was a frequent attendant at the laboratories of Professors Pettenkofer and Koch. On returning to Japan he applied the German method of bacteriological inquiry to the investigation of the cause of a contagious disease, called "beri-beri," indigenous to Japan. The results of this investigation are found in the *Aerztlichen Intelligenz Blatt*, in Munich.

THE NEW DIRECTOR AT THE TOWN HOSPITAL.

Dr. Riecos has resigned his post, and Professor Fuerbringer is to succeed him, having been summoned to Berlin. He was born in 1850 at Delitsch, in the province of Saxony, and pursued his medical studies from 1870 till 1874 at Jena and Heidelberg. At the latter place he entered into close relations with the Kliniker Friedreich. After his promotion Professor Fuerbringer became clinical assistant, a post he occupied until he obtained a Readership at Jena in 1879, when the office of the management of the Clinic for Children's Diseases and Diseases of the Skin was conferred on him. Since 1881 he has also conducted the district physical office.

MEDICAL SCHOOL SOCIETY.

The secretary of this Society, at a meeting on Jan. 28th, read the annual report; after which the election of managers took place, in which the privy councillor, Dr. Steinthal, and the grammar-school director, Dr. Kübler, were elected as chairman and vice-chairman; as secretaries, Dr. Taselowski and Dr. Brullow; and as treasurer, Dr. Korn. Then Dr. Taselowski reported on the cleaning of school-yards and the heating of class-rooms. Respecting the latter point, reference was made to the requirement that at the beginning of lessons the temperature should not be lower than 44° F. In the discussion several speakers alluded to the vitiated air in class-rooms and the insufficiency of ventilation, and it was recommended that the windows in schools be opened for a few seconds at the end of each hour in order to effect a thorough renewal of the air, care being taken to provide against draughts. School closets, it was unanimously agreed, should always be erected in a detached building, and should be flushed daily.

Berlin.

Obituary.

DR. ANGUS MACDONALD.

THE notice of Dr. Angus Macdonald's death, though partly expected from the serious nature of his illness, has yet come as a great and sudden blow to his many friends. Edinburgh medical circles have been deprived of one of their brightest ornaments; and modern Athens, lay and professional, grieves as it has not done since the untimely death of Warburton Begbie. This regret is not to be wondered at, for Angus Macdonald was not a common man. In his youth his lines lay in no pleasant places. Born in an agricultural parish in the north of Scotland, the *res angusta domi* necessitated his working for his daily livelihood, and he stood between the hilts of the plough until his manhood was nearly reached. But even when thus engaged his ambition soared, and in the evenings, when the day's work was over, he went to the parish schoolmaster and learned Latin. When he was sufficiently conversant with this, he went, a raw country lad, to Aberdeen University, and fortunately secured a bursary, which enabled him, with teaching, while a student, to keep the wolf from the door. He was a distinguished Arts student of the University, taking a foremost place in the classes; and when the Arts course was finished he entered the Divinity Hall, for he thought he would be a minister. His vocation, however, was not to be clerical, and after pursuing the study of divinity for a year he went to Edinburgh and attended the University as a medical student in 1860. The Edinburgh school was then in the zenith of its fame. John Goodsir taught anatomy as he alone could do it. Hughes Bennett, the model clinical teacher of medicine, formed his admiring circle of students in the wards. James Syme stood neat and calm and self-possessed, while he guided with unerring skill and rare dexterity the knife through difficult structures of the frame. James Simpson—"body of Bacchus—head of Jove"—spoke with the brilliancy of exceptional ability, and obtained enthusiastic admiration in his class-room. Robert Christison, the polished physician, the gentleman *sans peur et sans reproche*, told his young audience of men's numerous ailments and their remedies. The ardent nature of Angus Macdonald glowed under such a galaxy of talent, and he worked late and early, always taking a first position in his classes. Many of his fellow-students will remember his peculiar place—right in front of the professor; and his physique—the stooping shoulders, the broad square head, rarely lifted from the note-book, on which he wrote with an almost marvellous celerity. Occasionally, when some happy remark came from the professorial chair, Macdonald raised his face to smile, and one perceived then the keen piercing eye and the pale lineaments of his highly intellectual features. At the end of the session, when the class prize list was read out with Angus Macdonald's name first, students cheered, for they knew the man that deserved it had won the reward, and they felt that he was head and shoulders above his competitors. After obtaining the degree of M.D. of Edinburgh in 1864, he settled in practice in the city of his adoption, and step by step gained the foremost place in the branch to which he specially turned his attention. When Dr. Matthews Duncan went to London, Dr. Macdonald was recognised by the profession as his successor, and he nobly fulfilled the anticipations that had been formed of him. For twenty years he was a constant contributor to medical literature, and his style was terse, pointed, and true. His was also a familiar figure at the various clinical and obstetrical societies of Edinburgh, and until he died he held the appointments of Physician and Clinical Lecturer on Diseases of Women in the Edinburgh Royal Infirmary, Physician to the Royal Maternity Hospital, Edinburgh, and Lecturer on Midwifery and Diseases of Women at the Surgeons' Hall.

Digitized by Google

Thus, briefly sketched, was Angus Macdonald's career as a student and physician. It was a distinguished one. As a private gentleman he was singularly beloved, and ever ready with ripe counsel and wise encouragement to guide the young student who came to him for advice. He was a true friend, and the grasp of his hand was firm and manly, revealing the inner nature of his kindly heart. He spoke to all courteously; to those he liked he showed his genuine, open disposition, the pure heart, the charity that envieth not, and all the graces of the Christian character. Dr. Macdonald leaves a widow, two daughters, and five sons to mourn his early death.

E. D. L. GILLOTT, M.R.C.S., L.S.A.LOND.

ON February 6th Sheffield lost one of its oldest medical men, in the person of Mr. E. D. L. Gillott. He took the licence of the Apothecaries' Society in 1829, and became a member of the College of Surgeons in 1830, so that when he passed away he had been a member of the medical profession for considerably over half a century. His early life, his industry, and his devotion to his profession are thus spoken of by one who enjoyed his intimacy for fifty-seven years: "We were fellow-pupils in Dublin in 1829-30, where he distinguished himself by his marked indefatigable minute anatomical research, carried on during his long career in Sheffield, commencing with his becoming Lecturer on Anatomy at the Medical School, from first to last endeavouring to the utmost of his ability to keep pace with the times. Oft, in the hour of need, have I had an opportunity of testing the inestimable professional qualities of my departed friend, ever willing and ready to lend a helping hand in the hour of peril." Commencing as a general practitioner, he, after some years, joined the late Mr. S. Gregory, surgeon to the General Infirmary, at the Eye Dispensary, which the latter had some time previously established in a quiet unostentatious manner. A happy intercourse between these two continued for twenty years, until Mr. Gregory left Sheffield, and soon afterwards died. Mr. Gillott continued working the Eye Dispensary until 1877. On the appointment of his then colleague to the charge of the newly created special department at the General Infirmary the *raison d'être* for such a dispensary had ceased, and he willingly consented to its being closed. For many years, however, he had practised purely as a specialist, and both as an oculist and aurist obtained a wide repute; whilst his keen insight into everything passing in his specialty and his wide knowledge of its literature, British and foreign, were remarkable. He may truly be said to have always been a student. He attended meetings of the International Ophthalmological Congress, and frequently paid visits to Paris, Berlin, and Vienna, and each time took the opportunity of adding to his store of knowledge by visits to the various cliniques in those cities. At the time also when the ophthalmoscope had established its place as an instrument of extreme value, and at an age when most men would be loth to take up with "new-fangled" ideas, he visited a continental city, Vienna it is thought, where the opportunities would be good for mastering the use of an appliance of which he fully appreciated the importance and value. As a student he had attended Moorfields when Tyrrel was a surgeon there. He gradually declined practice, and for some years had retired altogether. His literary taste found him amusement and occupation at the library and at home. He was always ready with a classical or poetic quotation. Until recently he had been active and strong. He succumbed to the combined attacks of Bright's disease, with heart trouble, bronchitis, and asthma, but he bore his sufferings with exemplary patience.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At the monthly meeting of the members of this Association, on the 11th inst., Mr. Vacher read the report of the committee appointed to take action, along with representatives of other associations, to obtain better security of tenure of office for medical officers of health. Very little progress has been made, and it was resolved that the committee should continue to take such action as seemed desirable to secure the object in view. Mr. Vacher also submitted a further report with regard to cholera precautions.

Medical News.

UNIVERSITY OF CAMBRIDGE. — At a congregation on the 11th inst. the degree of M.B. was conferred on

Herbert Charles Walter Jones, Downing.

COLLEGE OF PHYSICIANS IN IRELAND.—At the February examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Simon Addis, Michael Joseph Boyan, Vesey Henry Wm. Davoren, Louis Demetriadi, William Hartford, William George Keanedy, George Okill, Thomas O'Callaghan, John William Power, Robert Dudley Algeo Stone, George Woods, Charles Augustus Young.

MIDWIFERY.—Simon Addis, Louis Demetriadi, William George Kennedy, John William Power, George Woods.

The undermentioned has been admitted a Member:—

Henry Plunkett Esmonde-White, Surgeon-Major, A.M.D.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 11th inst.:—

Castle, Charles Wigram Marshall, The Avenue, Blackheath.
Scatliff, P. Melancthon, M.R.C.S., Macaulay-road, Clapham-common.

The following also passed and received a certificate:—

Brooks, William Harrison, King David-lane, Shadwell.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH.—In the pass-list published last week the name "Herbert Peek" should have been Herbert Peck.

A FATAL case of poisoning by sewer gas has just occurred at Oldham.

ON the 16th inst. Sir James Crichton Browne delivered to the members of the Leeds Philosophical and Literary Society a lecture on the "Education of the Hand."

MEDICAL MAGISTRATE. — John Constable, M.D., Leuchars, has been appointed a Justice of the Peace for the county of Fife.

VACCINATION GRANT.—Dr. Dalston, of the Brough District of the East Ward Union, has been awarded the Government grant for efficient vaccination.

THE festival dinner in aid of the Extension Fund of St. Mary's Hospital is to be held on April 2nd, under the presidency of the Lord Mayor.

THE St. Petersburg Municipal Sanitary Committee has decided to set apart a portion of the Alexander Hospital for the clinical instruction of female students and to erect lecture-rooms for them.

A CHEMIST at Battersea named Gill has been committed to take his trial for manslaughter, a coroner's jury having found that the death of a young man was caused from the effects of a dose of opium given by him in mistake for a black draught.

THE first meeting of the Carmichael College Medical Science Association was held on Tuesday last, presided over by Dr. Gordon, when the opening address was given by Dr. J. Moore on the Relations of Clinical Teaching to the Work of the Society.

MUNIFICENT BEQUESTS.—Mr. James M'Ewan of the firm of Smith and Sharp, sugar brokers, Glasgow, has left legacies amounting to £22,000 to charitable institutions in Glasgow and the west of Scotland. Of this sum, the Royal Infirmary of Glasgow and the Western Infirmary each receives £5000.

THE HOSPITAL SATURDAY FUND. — The Board of Delegates of this fund met on the 13th inst., when Mr. Samuel Morley was unanimously re-elected President and Mr. H. N. Hamilton-Hoare honorary treasurer for the ensuing year. The Secretary reported that there was a credit balance at the bank of £500 after payment of the awards, amounting to £9500, and all expenses.

THE LATE DR. P. B. CONOLLY.—Two latten brasses have been erected, one at Netley and the other at Charing-cross Medical School, in memory of Dr. P. B. Conolly, who died whilst serving in the Camel Corps during the Gordon relief expedition. He was present at the siege of Plevna and the battles of Zlobani, Kambala, Ulundi, Kassassin, and Teb-el-Kebir, and received two medals with clasps, the Khédive's Star and Gold Cross of Roumania. The memorials are from the works of Mr. Gawthorp of Long-acre.

Digitized by Google

VALENTINES FOR HOSPITAL PATIENTS.—Some four hundred scrap albums, contributed by readers of the *Christian Million* newspaper, were distributed on Monday last, to the patients in the following London hospitals as valentines:—St. Thomas's, St. Bartholomew's, University College, Royal Free, Guy's, Shadwell Children's, London, Victoria Hospital for Children, Homœopathic, and Samaritan Free Hospital for Women and Children.

KIDDERMINSTER INFIRMARY.—The annual meeting of the management committee of, and subscribers to, this institution was held on the 5th inst., when a lengthy discussion took place touching the desirability of establishing a children's hospital in connexion with the charity. It was ultimately decided to convert a ward which has been occasionally used for the reception of patients needing isolation into a children's hospital, the cost (about £250) being defrayed by Mr. T. Lea.

LONDON FEVER HOSPITAL.—The annual meeting of the governors of this institution was held on the 11th inst. From the report which was adopted it appeared that during the year the total number of cases admitted to the hospital was 486. The mortality amongst patients amounted to only 4·04 per cent.—a lower percentage than that of any previous year. The annual subscriptions for the year amounted to £2215, being an increase of £210 on the previous year. The expenditure reached £8543, an increase of £1842.

ADULTERATION OF FOOD.—Dr. Redwood, the public analyst for the parish of Clerkenwell, has reported that during the past quarter he analysed 18 samples of milk, 17 of butter, and 2 of coffee. Of the 17 of butter, 12 were adulterated with foreign fat to an extent varying from 75 to 90 per cent., and convictions were obtained in seven cases. Of the 18 samples of milk, 3 were adulterated with 14 per cent. and 2 with 22 per cent. of added water, and convictions were obtained in each case. The 2 samples of coffee were adulterated with chicory to the extent of 20 per cent.

CHEAP FOOD FOR THE PEOPLE.—At a meeting recently held under the presidency of Dr. B. W. Richardson, the following resolution was unanimously carried:—"That in the opinion of this meeting the most practical mode of developing the best system of supplying cheap dinners and other meals for the people ought to include the establishment of public kitchens and depôts, at which the dinners and meals can be partaken, and from which they can be supplied to workshops, factories, and private houses. That such a system, supported by the general and influential public, would be immediately popular, and that the chairman be requested to communicate this view of working men themselves to the leading organs of public opinion." A committee has been formed to carry the above into effect.

VOLUNTEER MEDICAL STAFF CORPS.—The second regimental smoking concert took place on February 10th, at St. Stephen's Restaurant, Westminster, and was, we understand, a greater success even than the first of the series. It is gratifying to see the efforts of the committee meeting with such encouragement, as by means of entertainments of this description the men are brought together during the winter season, and that *esprit de corps* at which all regiments aim, and of which they are justly proud, is properly maintained. The concert under notice was given by members of No. 2 company, which consists of students of St. Mary's, London, and Guy's Hospitals, and they fully kept up the reputation of their respective schools. The chair was taken by Surgeon Norton, who commands the company, supported by Surgeon-Commandant Cantlie, Surgeon Casson, Surgeon Raw, Surgeon-Major Pearce (Artists), Surgeon Lane (18th Middlesex), and other officers who take a keen interest in the welfare of this corps. A most enjoyable evening was spent. The third concert of the series will be given early in March by the members of No. 1 company, which is formed by students from Charing-cross, Middlesex, University, and King's College Hospitals.

PRECAUTIONS AGAINST CHOLERA IN QUEENSLAND.—His Excellency the Governor of Queensland, with the advice of the Executive Council, has been pleased to appoint the following gentlemen to be medical officers of health, for the purposes of the regulations of the Central Board of Health for the treatment of persons affected with cholera, and for preventing the spread of that disease:—M. Mathison, M.D., Aramac; W. S. Webb, M.R.C.S., Blackall; F. H. V. Voss, F.R.C.S.Ed., Bowen; C. J. H. Wray, L.R.C.S., L.R.C.P.Ed., Brisbane; J. E. Usher, L.R.C.P.Lond., Brisbane; T. H. May, M.D., Bundaberg; E. A. Koch, M.D., Cairns; W. B. Kirkaldy, M.B. & C.M.Ed., Charleville; E. E. J. Mohs, M.D., Charters Towers; S. Candiottis, M.D., Clermont; G. A. Von Somerson, M.D., Cloncurry; W. Howlin, L.R.C.S.Ed., Dalby; E. M. Fitzgerald, L.R.C.P., Gayndah; C. E. Sharpe, L.R.C.P., Georgetown; T. L. Bancroft, M.B., Geraldton; H. Girdlestone, M.R.C.S., L.S.A.Lond., Goondiwindi; J. P. Ryan, L.R.C.S., Gympie; W. D. Bowkett, M.R.C.S., Herberton; W. C. C. Macdonald, M.B., Ingham; E. R. Webb, M.R.C.S., Ipswich; A. Cutfield, M.R.C.S., L.S.A.Lond., Mackay; E. K. Overend, M.B., Muttaburra; D. W. O'Connor, L.R.C.P. Ed., Maryborough; T. S. Dyson, M.R.C.S., L.S.A. Lond., Normanton; W. L. Marley, M.R.C.S., Port Douglas; W. T. Cuthbert, L.R.C.S.I., Ravenswood; W. F. Thurston, L.R.C.S. &c., Rockhampton; G. Comyn, B.M., Roma; R. H. Symes, L.R.C.S.I., Springsure; A. Orton, M.R.C.S., L.S.A.Lond., Stanthorpe; A. Nicoll, M.B., Tambo; A. E. Salter, M.B., Ch.B., Thursday Island; E. Roberts, M.R.C.S., Toowoomba; T. Ridgley, M.B., Townsville; F. Margetts, L.S.A. Lond., M.R.C.S., Warwick; H. Finlay, M.D., Winton.

CHAIR OF PHARMACOLOGY IN MELBOURNE.—We understand that in connexion with the University of Melbourne and the Pharmaceutical Society of Australasia new buildings have been opened by the Government, with a grant in aid of their furnishing, and another in aid of the professor's salary. The chair has been offered to, and accepted by, Mr. Alfred H. Jackson, B.Sc., M.P.S., F.C.S., Associate of Owens College, Manchester. This election is the latest addition to the number of professors emanating from Owens College, amongst whom we can recall Atkinson of Sandhurst, Bedson of Newcastle, Carnelly of Dundee, Dougan of Belfast, Napier of Richmond, Poynting of Birmingham, Smithells of Leeds, Sugden of Headingley, Tait of Baroda, Thomson of Cambridge, Thorpe of South Kensington, and Young of Clifton, besides several who hold posts in their *alma mater*, such as Hopkinson, Dreschfeld, Collier, Thorburn, Whitney, Swaniek, Harris, Haslam, and others. Prof. Jackson was also a distinguished student in the Pharmaceutical Society's School at Bloomsbury-square, W.C., where he won the Council's Silver Medal, &c., in 1878. He has published several papers on pharmaceutical subjects, such as "Dialysed Iron," "Tartar Emetic," Essential Oils of Cinnamon and Cassia," &c. His chief training has been in the science and medical departments of Owens College.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ABBOTT, C. B., M.R.C.S., L.K.Q.C.P.I., has been reappointed Medical Officer of Health for the Braintree Rural Sanitary District, for one year.

BROCKATT, A. A., L.R.C.P., M.R.C.S., has been appointed Resident Accoucheur to St. Thomas's Hospital.

CAMPBELL, W. MACFIE, M.D.Ed., M.R.C.S., has been appointed Consulting Surgeon to the Liverpool Northern Hospital.

COOPER, CHARLES B., L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., late Assistant House-Surgeon, has been appointed House-Physician to the Liverpool Northern Hospital, vice T. A. Bradshaw, B.A., M.D. resigned.

CROWDY, F. D., M.B.Oxon., M.R.C.S., L.S.A.Lond., has been re-appointed House-Surgeon to St. Thomas's Hospital.

FISHER, ALFRED, M.R.C.S., L.R.C.P.Ed., late Ambulance Surgeon, has been appointed Assistant House-Surgeon to the Liverpool Northern Hospital, vice Charles B. Cooper, L.R.C.P.Lond., M.R.C.S., promoted.

GODFREY, A. E., L.R.C.P., M.R.C.S., has been appointed Assistant House-Physician to St. Thomas's Hospital.

GOODDY, E. S., M.R.C.S., L.S.A.Lond., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

HAIG, F. M., M.R.C.S., L.S.A.Lond., has been reappointed Non Resident House-Physician to St. Thomas's Hospital.

HAMILTON, GEORGE, F.R.C.S.Ed., L.R.C.P., has been appointed Honorary Surgeon to the Liverpool Northern Hospital, vice W. Macfie Campbell, M.D., resigned.

HAW, WALTER HERBERT, B.A., M.R.C.S., L.S.A.Lond., has been appointed Resident Surgeon to the Portland Town Dispensary Henry-street, N.W.

HOAD, WILLIAM, M.B., C.M.Edin., has been appointed Government Medical Officer, Health Officer, Public Vaccinator, and Commissioner of Lunacy for the Seychelles Island, vice Lepper, resigned.

HOPKINS, JOHN W., L.R.C.P., L.R.C.S., has been appointed Medical Officer for the Snettisham District of the Dorking Union.

HUGHES, Mr. THOMAS W., has been appointed Medical Officer for the Aberdaran District of the Pwllheli Union.

HUTTON, J. S., L.R.C.P., M.R.C.S., L.S.A.Lond., has been reappointed Resident House-Physician to St. Thomas's Hospital.

KIDD, CAMERON, L.R.C.P., M.R.C.S., has been appointed House-Surgeon to St. Thomas's Hospital.

MAKINS, GEORGE HENRY, F.R.C.S.Eng., has been appointed Assistant Surgeon to the Evelina Hospital for Children.

NICHOL, F. E., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

ORCHARD, ALFRED, L.R.C.P., M.R.C.S., has been appointed Medical Officer for the First District and the Workhouse of the Ashby-de-la-Zouch Union.

PARSONS, F. G., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

PLOWMAN, S., F.R.C.S., L.R.C.P., has been reappointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

POUND, Mr. CLEMENT, has been appointed House-Surgeon to the Middlesex Hospital.

RITCHIE, E. D., B.C.Camb., M.R.C.S., L.S.A.Lond., has been re-appointed Resident House-Physician to St. Thomas's Hospital.

STAVELEY, W. H. C., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

WARRILLOW, EDWARD S., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer and Public Vaccinator to the Headcorn and Alcomb District of the Hollingbourn Union, vice Warrillow, deceased.

WEAVER, JOHN J., M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the Oldham Infirmary, vice Holton, resigned.

Births, Marriages, and Deaths.

BIRTHS.

ASHWORTH.—On the 17th inst., at Halstead, Essex, the wife of J. Henry Ashworth, M.R.C.P.Ed., of a son.

CARR.—On the 8th inst., at Long-street, Devizes, the wife of Alfred Alexander Carr, M.R.C.S., of a daughter.

CROSS.—On the 11th inst., at Stanhope-terrace, Regent's-park, the wife of John Cross, M.D.Camb., of a daughter.

EVANS.—On the 14th inst., at Denmark Lodge, The Grove, Clapham-common, the wife of Lewis Evans, L.R.C.P.Ed., L.F.P.S.Glas., of a son.

HOFFMAN.—On the 14th inst., at Coombe Lodge, West-hill, Putney-heath, the wife of H. W. Hoffman, M.B., of a daughter.

MILBURN.—On the 14th inst., at 43, Claremont-square, N., the wife of F. L. Milburn, M.R.C.S., &c., of a son.

MOORE.—On the 6th ult., at Langley, St. Andrews, Jamaica, the wife of York T. G. Moore, L.R.C.P.Ed., M.R.C.S., of a daughter.

VLIELAND.—On the 15th inst., at Sydney Lodge, St. Thomas, Devon, the wife of C. J. Vlieland, M.R.C.S., of a daughter.

MARRIAGES.

ALLDEN—KING.—On the 3rd inst., at St. Peter's, Cranley-gardens, by the Rev. Hon. F. E. C. Byng, Vicar, and Chaplain to the Queen, George H. Allden, M.B., of Shirley, Southampton, to Mary Manuela King, widow of D. A. King, M.B., and third daughter of Mrs. Stubbs, of 6, Edinburgh-terrace, Kensington.

BAILLIE—JACKSON.—On the 10th inst., at St. Catherine's Church, Wakefield, Peter Baillie, M.B., of Whitworth, Lancashire, to Violet Hamilton, daughter of John Jackson, of Heathfield Lodge, Wakefield.

CLARK—WHITE.—On the 16th inst., at St. James's, Paddington, Oscar William Clark, M.B., of Gloucester, fourth son of the late Frederick Clark, of Cowick, Yorkshire, to Kathleen Emily, fourth daughter of Robert Faulder White, of Sussex-gardens, Hyde-park, W.

GULLAND—BRADISH. On the 10th inst., at St. Matthew's Church, Cheltenham, Surgeon-General Alexander Gulland, A.M.D., of Berkeley-villas, Cheltenham, to Margaret, second daughter of the late William Bradish, of Southern House, Cheltenham.

PEARSON—SNELLER.—On the 10th inst., at St. George's, Canterbury, Harry Pearson, M.R.C.S., of West Malling, Kent, and younger son of D. Gilbert, of Buckingham Palace-road, London, S.W., to Edith Hill, third daughter of the late James Vidgen Sneller, of Canterbury.

SMITH—CUBITT.—On the 15th inst., at St. Peter's Church, Bournemouth, Protheroe Smith, M.D., of Park-street, Grosvenor-square, London, to Emma, widow of Edward George Cubitt, Esq., late of Honing Hall, Norfolk.

DEATHS.

DE'ATH.—On the 11th inst., at Buckingham (suddenly), Robert De'Ath, M.R.C.S., L.S.A.Lond., aged 57.

HOPE.—On the 10th inst., at Auriol-road, West Kensington, George Carfrae Hope, M.D., F.R.C.S.Edin., in his 75th year.

LANCHESTER.—On the 13th inst., at Bracondale, Norwich, Thomas William Lanchester, M.D., formerly of Yoxford, Suffolk, aged 81.

MORRIS.—On the 12th inst., at St. Mary's House, Chester-le-street, Walter Cameron Morris, M.B., M.R.C.S., aged 35.

PAYNE.—On the 13th inst., at Clifden, Connemara (suddenly), Christopher James Payne, M.D., aged 65.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, February 22.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Charles Stewart: On the Organs of Hearing.

SOCIETY OF ARTS.—8 P.M. Prof. F. Guthrie: Science Teaching (Cantor Lecture).

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. R. Brudenell Carter: On the Combined Action of Cocaine and Nitrate of Silver in certain Superficial Affections of the Eyes.—Dr. A. E. Sansom: Notes on Severe Endocarditis, with special reference to Cause and Effect.—Dr. W. H. White: A case of Aneurysm of the Aorta.

Tuesday, February 23.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. Charles T. Newton: The Unexhibited Portion of the Greek and Roman Sculptures in the British Museum.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. Cayley: A case of Thoracic Aneurysm treated by the Introduction of Steel Wire into the Sac.—Mr. George Pollock: On the Changes which occur in Bone and Soft Tissues after Amputation of a Limb, and from certain other conditions.—Mr. J. Bland Sutton: A case of General Seborrhœa, or "Harlequin" Fœtus.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8.30 P.M. Mr. A. W. Howitt: On Australian Medicine Men.—Mr. Adolphus Mann: On the Numerals of the Yoruba Nation.

Wednesday, February 24.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Charles Stewart: On the Organs of Hearing.

HUNTERIAN SOCIETY.—8 P.M. Mr. Corner will take the chair as President.—Dr. Stowers: Rodent Ulcer.

SOCIETY OF ARTS.—8 P.M. Prof. W. C. Unwin: The Employment of Autographic Records in Testing Materials.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown by Drs. Mansell Moullin, Grigg, Fancourt Barnes, and others. Adjourned Discussion on Dr. Chalmers' paper on Puerperal Septicæmia.

Thursday, February 25.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. W. Boyd Dawkins: The Ancient Geography of Britain.

SOCIETY OF ARTS.—8 P.M. Prof. W. N. Hartley: Photography and the Spectroscope in their Applications to Chemical Analysis.

Friday, February 26.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Charles Stewart: On the Organs of Hearing.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. C. Mansell Moullin: Traumatic Inguinal Aneurysm, Rupture of Sac, Ligature of the Common Femoral and External Iliac Arteries.—Mr. Charters Symonds: A case of Aneurysm occurring in Stump.—Dr. Goodhart: Intussusception of the Upper Part of the Jejunum.—Mr. Barker: Acute Intestinal Obstruction followed by Acute General Peritonitis, Abdominal Section, Release of the Implicated Bowel, Peritoneum thoroughly Sponged out, Rapid Recovery.—Mr. Godlee: Case illustrating the Effects upon the Eye of Injury to the Sympathetic in the Neck (living specimen).

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Mr. A. A. Common: Photography as an Aid to Astronomy.

Saturday, February 27.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Subscriptions may be sent to the treasurer, the Dowager Lady Stanley of Alderley, 40, Dover-street, W., or to the honorary secretary, Mrs. Garret Anderson, M.D., 4, Upper Berkeley-street, W. A meeting of subscribers and friends will be held at 4 P.M. on Saturday, Feb. 20th, in the Medical Society's Rooms, 11, Chandos-street, Sir W. W. Gull, Bart., M.D., in the chair.

Mr. G. W. Hambleton.—We do not think our correspondent can be bound to publish the results of his researches until he deems such researches complete.

MUMPS.

To the Editor of THE LANCET.

SIR,—There is a rule in force at the principal schools of the town in which I reside that boys and girls of a family are forbidden to attend school if one of their number suffers from mumps, even in its initial stage, although a strict quarantine is observed. I am anxious to know if the profession considers this rule both wise and necessary. I myself am not competent to give an opinion, as I passed thirty-two years in the Indian Medical Service, and had no experience of the above disease. I shall feel much obliged to those who have the experience if they will express their opinion in your journal.

I am, Sir, yours faithfully,

J. A. C. HUTCHINSON, M.D.,
Surg.-Gen. Ret. List.

Feb. 15th, 1886.

"FRACTURE OF THE CLAVICLE."

To the Editor of THE LANCET.

SIR,—In reference to the communication of Dr. E. D. McNicoll in your issue of the 30th ult., allow me to say that I had a case of fracture of the clavicle in a lad of fourteen, the result of a fall on the ice whilst sliding on Jan. 10th last. Still, serious accidents during the ice season, other than immersions, seem to be wonderfully infrequent.

Believe me, Sir, yours faithfully,

G. POUND

Odiham, Feb. 2nd, 1886.

LITERATURE OF SNAKE POISON AND SELF-VINDICATION.

UNDER the above title Dr. Gopaul Chunder Roy writes to us complaining that it does not afford much encouragement to workers for the sake of science to find their researches ignored and shelved into obscurity by brother members of the medical profession. Our correspondent states that he has in India been singularly unfortunate in this respect, and in proof of this assertion he refers to an article written by him, and published in 1876 in the *Indian Medical Gazette*, on the action of snake-poison of the blood, in which, against the accepted theory of Sir Joseph Fayrer and Drs. Brunton, Lewis, Cuningham, and Weir Mitchell, he attempted to prove that snake poison has a decided action on the blood. From Mr. Richard's small book, "The Landmarks of Snake Poison Literature," Dr. Roy gathers that the same view has been endorsed by two prominent contributors on the subject—viz., Dr. Wolfenden, late Professor of Physiology at the Charing-cross Medical School, and Dr. Lacerda. In the paper already alluded to, Dr. Roy also stated that the local effect of cobra poison on the blood was not that of a vital change, a view afterwards endorsed by Dr. Mitchell and Sir Joseph Fayrer, and recommended the administration of chlorate of potash, anticipating Dr. Lacerda's discovery of the antidotal virtue of permanganate of potash. Again, our correspondent states that in 1872 he read a paper on the solvent action of papya juice on the nitrogenous articles of food; and although the first to make a systematic inquiry on the subject, his labours were ignored by M. Wurtz, who in 1880 isolated the ferment, and named it "papyaine." Dr. Roy also alludes to his researches on the nature of malaria, and to a description of the phenomena met with in the blood, which was embodied in his official report for 1881, and is practically identical with the description of Professor Bizzozero's blood particles, given in this journal on Jan. 21st, 1882. While fully aware of the necessary imperfections of his original researches, our correspondent claims amongst his co-workers the humble place of an artist who, though not skilful enough to give the last finishing touch, has yet done his best to add one brick to the building of the superstructure.

M. Dani.—Fear or nervous apprehension can never produce, though it may greatly aggravate the symptoms of, organic disease.

A CURIOUS COMPLICATION IN A MIDWIFERY CASE.

To the Editor of THE LANCET.

SIR,—The following case may be of sufficient interest to be placed before the readers of THE LANCET.

Mrs. F——, aged twenty-seven, was some time ago confined of still-born male twins at the eighth month. When first seen by me, twelve hours before labour commenced, she complained of pain in the right side. On physical examination externally, I found the uterus enormously distended, with a projection to the right of its fundus, which was hard and tender; the fœtal hearts were not audible. At 11 A.M. next day (fifteen hours later) there were distinct labour pains; the os was dilated to the size of a shilling, and the head of the fœtus was believed to be presenting. At 6 P.M. the os was almost fully dilated, but no presentation could be felt. At 7 P.M., as there had been no advance, and the membranes were tense and protruding through the nearly dilated os, I ruptured them, expecting to hasten labour by so doing, when something tough, which was diagnosed to be the breech, descended and impinged on the finger. Having waited some time with the patient, and there having been no advance in the labour, the os remaining immovable, I left. I was, however, again summoned to the patient at 10.30 P.M., when on arrival I found that another sac of membranes had ruptured, and that a stream of liquor amnii, extending one or two yards from the bed, had escaped, literally soaking the bedclothes. Examining per vaginam, I found the os fully dilated; but my finger impinged on a third sac, thin this time, with the vertex of the fœtus above it; having ruptured it, the head descended in the second position. The following morning at 2.30 the first child was born, and immediately afterwards the second, feet foremost, and with it a bag of membranes, which I ruptured, but not till it had protruded from the vulva.

In this case there appears to have been four sacs of membranes to two fœtuses; but on inquiring for the placenta later on, I found that it had unfortunately been destroyed; it might have been interesting to have examined it. The following facts seem to me to be of interest: (1) that there appear to have been four sets of membranes, and (2) that the second sac was mistaken for the breech, which, however, was not finally diagnosed till all other imaginary presentations had been rejected.

I am, Sir, yours faithfully,

Newhaven, Jan. 4th, 1886. ED. TONGUE YEATES, L.R.C.S.I., &c.

A LARGE NEW-BORN INFANT.

To the Editor of THE LANCET.

SIR,—On Feb. 6th I attended Mary B——, aged forty-four, in her twelfth confinement. After a labour of five hours, with very strong pains all the time, the child, a female, was born, weighing directly after birth 13½ lb. The mother also seems to have a large fibroid. She is much exhausted by the labour, but otherwise is doing well.

I am, Sir, yours truly,

Guy's Hospital, Feb. 10th, 1886. HERBERT V. RAKE (extern).

PLACENTA PRÆVIA; TWINS.

To the Editor of THE LANCET.

SIR,—I forward for insertion particulars of two cases. I have neither seen nor heard of similar ones, and therefore think they are worth bringing before the profession through the medium of THE LANCET.

On Oct. 22nd, 1883, I was called to see Mrs. G——, aged forty-two, the mother of a family, who was then in her seventh month of pregnancy, and had been taken with severe flooding. On questioning her I learned that she had had several attacks of flooding prior to that date. On examination, I found it to be a case of placenta prævia. I plugged the vagina, administered the usual remedies in such cases, and ordered perfect quietness, acquainting the husband with the nature of the case and its probable result. Next day I removed the plug, and found everything quiet; there was no further hæmorrhage. On the 26th I was again sent for, the patient having had another attack of flooding. I told the husband it would be necessary to deliver her, and requested him to obtain assistance. He called on my friend, Dr. Thomas O'Reilly, one of our oldest practitioners, who wrote to me saying he would call on me at 7 A.M. next day, being unable from pressure of business to see me the same evening. Next morning we called to see the patient. Dr. O'Reilly verified my diagnosis, and, having previously informed the husband and everything being in readiness, we proceeded to deliver. Having pushed the placenta aside and ruptured the membranes, I found, to my astonishment, that I had to encounter a regular mass of hands and arms. I remarked that I thought there was more than one fœtus, and finally succeeded in seizing a foot and delivering a child; after a little manipulation, Dr. O'Reilly brought about respiration. As I was positive that I had felt more than two hands, I again explored the uterus and discovered a second child, which, after the membranes had been ruptured, was delivered with little difficulty, its birth having been preceded by the placenta belonging to the first child. The second placenta was then removed. Both children were respiring well, and the mother had not apparently suffered as much from the shock as I had anticipated. I need hardly say my attention was thenceforward directed principally to the mother. That evening her temperature and pulse were rising somewhat. She slept a little during the day and the same evening. Next morning the pulse had risen to 130 and the temperature to 104°. During the two following days (28th and 29th) the pulse and temperature kept at about the same elevation. The flow was extremely scanty. The patient did not complain of much tenderness.—Oct. 30th: Pulse 135; temperature 105°.—31st: Pulse 110; temperature 101·5°.—Nov. 1st: Pulse 95; temperature 100·5°; the patient felt pretty comfortable.—2nd: Pulse 85; temperature 99·5°. Next day I was summoned to see the patient before my usual time of calling, as she had severe hæmorrhage. On my arrival, I found her almost moribund. She died about noon. She had slept well the previous night, and had taken tea and toast for breakfast that morning, as she felt very well. I had noticed when I first examined the patient that her veins, especially about the labia, were in an extremely varicose condition, and this may to a certain extent account for the fatal result when everything looked favourable on the seventh day after delivery. Both children lived and thrived well until the following summer, when they succumbed to cholera infantum.

I look upon this case as a unique one. In an extensive midwifery practice of twenty years it was the first case of placenta prævia I had met with, and I have not seen a similar case recorded. Placenta prævia with a single child is bad enough; but with twins it is so much worse that the nearly successful issue is, I think, worth being recorded.

I am, Sir, yours truly,

CHARLES J. S. DIGGES, M.R.C.S., &c.

St. Louis, Mo., U.S.A., Oct. 29th, 1885.

"PSORIASIS ECZÉMATEUSE."

To the Editor of THE LANCET.

SIR,—I should be very grateful to my professional *confrères* for any suggestions as to treatment in the following case.

A lady, aged about sixty, has suffered for the last eight months from what the French style "psoriasis eczémateuse." It first made its appearance as a red spot on the finger under the wedding ring last summer, from which time it has gradually spread over the entire palmar surfaces of both hands, the exterior surfaces of the digits, and to some extent that of the metacarpus. The hands at first presented the following appearance:—Epidermis generally thickened, and peeling in large, dry flakes, from which, with forceps and scissors, the shape of the fingers might be removed, the cutis underneath being much reddened and hyperæmic. Under treatment, the large flakes gave place to more of a fine branny desquamation. In the flexures of the palms there have been large cracks, running along the whole width of the hand, and rendering extension difficult and painful, and all the time there has been more or less loss of tactile sensation, apparently owing merely to the thickened epidermis. The disease is quite dry, and devoid of moisture or weeping; and although limiting itself to the hands, there is something of a similar nature about the toes and scalp. General health good. No specific history; no rheumatic or gouty diathesis; no albumen or sugar in the urine. The only previous ailment appears to have been an eczématous ulceration of one leg. Mercurials in all forms and combinations, lead, zinc, salicylic acid, borasic acid, and liquor carbonis detergens have been used both in lotions and ointments; but improvement goes no further than the lessening of the thickness of the flakes and of the amount of desquamation. Internally, iodide of potassium, Easton's syrup, and arsenic have been used.—Yours truly,

Jan. 26th, 1886. SANS SUCCÈS.

WARLOMONT'S MANUAL OF ANIMAL VACCINATION.

To the Editor of THE LANCET.

SIR,—The review with which you this week favour my translation of the above work is likely to create some very erroneous impressions, and the hasty conclusions drawn are scarcely worthy of THE LANCET. I must ask you therefore, in common fairness, to be allowed to correct a few of the mistakes made by the reviewer, whom I would remind that ere a man condemns a book for its want of "exact evidence" he should himself take the trouble to make *exact quotations*.

The statement that "500 cases of vaccination met with 499 successes" should have been 479 successes, or a proportion of 96 per cent. Then, Dr. Allard did not obtain "sixteen vesicles out of every hundred;" but *sixteen vesicles out of a total of forty-four insertions*, the stored calf-lymph used having taken "eighty-six days" (from Oct. 6th to Dec. 31st) in transmission to the tropics, and having been subjected to a "temperature rising, even in the cases and trunks, to from 28° to 30°" (Centigrade). The reviewer then says this is "a result far below the success obtained with calf-lymph produced in this country"—hardly a fair statement, considering the conditions (at Vivi, Congo) and the length of time intervening between the collection and insertion of the vaccine. Then, the translator is credited with something which he has never written. I never objected to the vaccination-lancet being "used for other purposes." I object to the use of the lancet *at all*; and I maintain, as a matter of fact, that the majority of practitioners do *not* use that "reasonable care" in cleansing their lancets which could alone justify the use of any instrument in more than a single case of vaccination. Again, I have never stated that its "unnecessary sharpness is incapable of remedy." The unnecessary sharpness is one of the attributes of this careless reviewer, who would do well to take a few lessons in accuracy ere he dares to say that a purely scientific book "can scarcely claim to rank as a scientific work." The reviewer has omitted to note the discussion of certain experiments in connexion with vaccino-syphilis, which have recently been prominently quoted, as proof of the truth of an as yet unproved hypothesis. I have the private admission of the best authority on this matter that the "'proof' may not be absolute." I say *it is not absolute*; nor is it scientific. At present it is merely clinical.

Trusting you will do Dr. Warlomont and myself the justice to insert this letter in your next issue,

I remain, Sir, your obedient servant,

ARTHUR J. HARRIES.

(Translator and Editor of Warlomont's Manual of Animal Vaccination.)

Pall Mall East, S.W., Feb. 13th, 1886.

*** We gladly make the numerical corrections to which Dr. Harries directs attention, but the argument remains the same. Reference to Dr. Allard's experience was made simply because in this instance the insertion success was given. A statement of success which does not include insertion success is of much less value. Dr. Harries appears to be unnecessarily severe in his remarks upon our review. We would desire to call his attention to the following:—

In his letter he states:	In his book, p. 163, we find:
"Then the translator is credited with something he has never written. I never objected to the lancet being used for other purposes."	"Objections to the lancet:—Probably used for operations other than vaccination."
"Again, I never stated that its unnecessary sharpness is incapable of remedy."	"As a rule, a lancet is too sharp for efficient vaccination."

CHRONIC URTICARIA.

To the Editor of THE LANCET.

SIR,—Here is an *opprobrium medicorum*. Will any professional brother assist me? It is a case of chronic urticaria. The patient had an attack of subacute rheumatism in September last, and the rash first made its appearance then. The rheumatism has quite left him for several weeks, but the rash keeps coming and going; or, rather, I should say, it did keep coming and going, but it is now quite permanent, and covers his body in large crescentic patches from the head to the feet. The irritation is very severe at times, utterly destroying sleep, and rendering the patient's life miserable. I have prescribed various alkalies and salines, rhubarb and soda, soda and nux vomica, potass and nux vomica, iodide of potassium, bromide of potassium, acids and nux, quinine and acids, quinine and alkalies, colchicum and alkalies, belladonna and alkalies, serpentaria with soda and carbonate of magnesia, Fowler's solution of arsenic, bismuth, bismuth with soda and hydrocyanic acid, Donovan's solution. Externally: Baths of various kinds, soda baths, bran baths, lotions of acetate of lead and ammonia, acetate of lead and spirit, bichloride of mercury, oxide of zinc, carbolic acid, Condy's fluid, borax, chlorate of potass. Some of these have afforded relief for a time, but the rash always returns. I have consulted two eminent London physicians—one of special repute in such cases—but to no advantage. I may as well add that the patient has been carefully looked after in regard to diet, and that he wears silk underclothing.

Can anyone assist me in the treatment of this case? If so, they will confer a very great favour upon my afflicted patient, and ensure the gratitude of

Yours truly,

Park-road, N.W., Feb. 17th, 1886. J. BRISBANE, M.D.

NEW MUFF-WARMER.

MR. F. J. HEDGCOCK, surgical instrument maker, of 138, Grosvenor park, Camberwell, S.E., has introduced to the notice of the profession a new muff-warmer. The body is made of block tin, covered first with flannel, and then with plush of various colours, and fitted with a plated screw nozzle. This, when filled with boiling water and carried in the muff, will keep warm for about three hours, and will be found a useful preventive of chilblains for lady patients.

Mr. E. Wright.—In the course of a few days.

"FRIENDLY SOCIETIES' MEDICAL INSTITUTIONS."

To the Editor of THE LANCET.

SIR,—In your issue of the 30th ult. a letter appeared signed "Fairplay," and also some other correspondence, on the above subject. For nearly two years I have acted as medical officer to a very large institution of this kind, and think it but justice to state that all are not to be measured by the same standard. I have always found the committee ready to act in a spirit of kindly co-operation, with a desire to render (whilst they also expect to receive) the courtesy dictated by common sense. They are mostly just and intelligent men; and though I must admit having on rare occasions received incivility from members, most of them show great consideration for the "doctor," in trying to save him as much annoyance as possible. On the part of the committee there has been no want of liberality, but, on the contrary, a strong wish expressed that the remuneration should be sufficient to enable the medical officer to maintain his position as a professional man and at the same time uphold the credit of the institution. With regard to the well-to-do members, they are only admitted on the condition that they belong to some registered society; consequently, they have worked their way up, and is it fair that they should be excluded from the society which they helped to found, and from benefits which their own providence and enterprise have obtained, even though they may at last be independent of them?

I sincerely sympathise with "Fairplay" in his unpleasant experience, and hope that the publicity given to both sides of the matter will induce all these institutions to strive after a much higher standard, as only thus can they command public sympathy and conciliate professional regard. I am, Sir, yours faithfully,

Feb. 16th, 1886. MEDICAL OFFICER (F.S.M.I.).

Mr. P. B. Stubbs.—The name will appear in the next official list.

Mr. W. T. Brooks.—In an early number.

"SYMPATHETIC IRRITATION OF THE PNEUMOGASTRIC."

To the Editor of THE LANCET.

SIR,—Mr. Tower-Smith's letter of to-day's date recalled to mind your annotation (Oct. 3rd, 1885, p. 639) on Dr. Harkin's treatment for cholera. It certainly seems hopeful. I would suggest the trial of a seton in place of a blister, if the latter should fail. If the treatment indicated should be adopted, it would, of course, be extremely interesting to learn the result. I am, Sir, yours truly,

R. J. SHEPHERD, M.D.

St. Olave's Union Infirmary, Rotherhithe, S.E., Feb. 13th, 1886.

I. Burton may refer to the report of the Obstetrical Society in our present number.

SEA-SICKNESS.

To the Editor of THE LANCET.

SIR,—Years ago most passengers by sea spoke of the plan mentioned in your last week's issue (p. 335) as the old and only good thing for sea-sickness. From observation of hundreds of cases, I believe that the benefit arises entirely from the horizontal position, and that lying "head to bow" does not diminish the severity of the illness. After trying most remedies, I found most benefit from chloroform applications to the auditory meatus. I am, Sir, yours truly,

Feb. 16th, 1886. M.B., C.M.

THE

Erasmus Wilson Lectures

ON

EVOLUTION IN PATHOLOGY.

Delivered at the Royal College of Surgeons.

BY J. BLAND SUTTON, F.R.C.S.,

ASSISTANT-SURGEON TO THE MIDDLESEX HOSPITAL, AND LECTURER ON COMPARATIVE ANATOMY.

LECTURE III.

THE ETIOLOGY OF NEOPLASMS.

MR. PRESIDENT AND GENTLEMEN,—The term "tumour" has been applied to so many kinds of growth, and used so loosely, especially in clinical work, that it ceases to carry with it any definite significance. It is necessary to adopt some rigorous limitation to the term, or choose a name which shall enable us to discriminate between true tumours and the curious medley with which by the majority of writers they are confounded. A neoplasm may be defined as *a new growth characterised by histological diversity from the matrix in which it grows; it is distinguished from inflammatory new formations by the variety of its forms, mode of origin, and the frequent inherent tendency it has to increase.* This definition excludes hyperplasia of organs, infective granulomata, and the like. With regard to the histological diversity exhibited by a neoplasm, it should be mentioned that it may more or less resemble the matrix tissue, but certain features may always be detected whereby their heteroplastic nature may be demonstrated.

Few subjects have exercised the ingenuity of pathologists more than the etiology of neoplasms. It is unnecessary to recapitulate the various theories which from time to time have found adherents. There is no exclusive theory which will explain the causation and mode of origin of all known neoplasms; indeed, the various groups require separate consideration. The most scientific method of grouping neoplasms is an embryological one, leaving the histological details to determine the varieties. This mode of classification assumes considerable importance when considering the etiology of neoplasms. In this way they may be arranged in three groups: (1) the Mesoblastic group, including the connective-tissue growths; (2) the Epiblast and Hypoblast group, comprising adenomata, carcinomata, and papillomata; and (3) the Teratomata—neoplasms containing tissues derived from the three embryonic layers.

Cohnheim's theory, which ascribes the origin of neoplasms to persistent rudiments, is of all hypotheses that which has most to recommend it, if the term "tumour" be used in its most restricted sense. Throughout this lecture the expression "germinal rudiment" will be used in a more extended sense than that in which Cohnheim employed it. At the outset it will be well to ask the question, Do germinal rudiments, such as Cohnheim's theory demands, exist? and have we any evidence to show that such germs may become tumours? The origin of true cysts from functionless ducts and tubules is a fact which no one can dispute; for example, the cystic dilatation of the tubules comprising the parovarium, paradidymis, and ducts of Gartner in man and animals. If we receive without demur the origin of cystic structures from functionless tubular organs, or cyst-germs, as we may call them, why should the origin of solid neoplasms from rudiments be doubted, especially if such untransformed tracts of tissue can be demonstrated unequivocally to be heteroplastic in their nature? Of course it is far easier to demonstrate the origin of cysts from pre-existing germs than in the case of neoplasms it is ever likely to be. Nevertheless, we are certainly able to show that in the region where particular tumours are more prone to occur, there is embryological testimony to explain why they occur there. An epithelioma on the lip is what would be expected, but a similar growth starting in the midst of a block of cartilage is incomprehensible. In the same way a piece of cartilage in the midst of the shaft of a femur of a boy of five years is cartilage in the wrong place; nevertheless, such islands are to be met with by those who care to expend time and labour in searching for them. Their existence has been known for some years, and, as Virchow was the first to point out, they may in later life become the starting-point of enchondromata. I have seen very many of these cartilage islands, especially in connexion with the epiphyses and diaphyses of long bones, in rickety animals and children. Not only do these examples teach us in the most positive terms that embryonic rudiments of enchondromata exist, but they teach us something of the evolution of neoplasms. In the fact that at an early age our skull is mainly cartilage, we agree with the cartilaginous fishes, sharks, rays, and the like, whose skulls never advance in development higher than cartilage impregnated with salts of lime; and as we advance to osseous fishes and amphibians the overlying bones gradually bring about absorption of the cartilage in different places; but much exists throughout the life-time of the animal, and in the skulls of mammals, even the highest, we find traces, in the oldest, of this important matrix tissue, yet in spite of this some cavil and say embryonic rudiments cannot exist in the adult. Surely they are not in earnest. Frequent spots for the existence of these belated rudiments are the region asterion immediately posterior to the external auditory meatus, the neighbourhood of the nasal fossæ, the septum nasi, the lower jaw, and the vertebræ. The regions just mentioned are favourite situations for enchondromata and osteomata. A true osteoma may be regarded as simply a higher development of an enchondroma. If, then, we find a cartilage island, it would be impossible to say, supposing it to develop into a neoplasm, whether it would become a cartilaginous or an osseous neoplasm.

Moles and nævi may be regarded as tumour germs; many instances are on record where a small nævus untreated in early life later formed an angioma of considerable dimensions, and became a source of danger. All germs or rudiments do not become tumours. Three courses are open to them: (1) they may later in life undergo transformation into normal tissue; (2) they may remain quiescent throughout a long life; (3) irritation may stimulate them into abnormal activity. As to what constitutes irritation in this sense, nothing at present is definitely known. If we admit the origin of enchondromata, osteomata, and angiomata from rudiments, need we doubt the origin of other varieties of mesoblastic tumours from similar sources? There is this important fact in their favour—they are always confined to regions of the body where the elements of which they are composed are to be unequivocally demonstrated.

Before dismissing this question attention must be given to the sarcomata. I have no doubt that many cases of round-celled sarcomata are not genuine neoplasms, but the result of the irritation of micro-organisms. It is very necessary to be particularly cautious in deciding whether a given growth composed of round cells be a sarcoma or the result of a specific irritant, and more so if there be more than one growth present. Observations on animals have made me very sceptical regarding round-celled sarcomata. Mr. Pearce Gould has recently analysed the relation, which appears to exist in very many instances, between an injury and the appearance of a sarcoma, and has collected a goodly list of cases in support of the view in a paper read before the Medical Society in 1885. So far as my observations on animals have extended, it is interesting to note that sarcomata are found with greater frequency in those parts exposed to injury. In fish, the tails and fins are the parts most affected. In frogs, the limbs are the most frequent situations; in birds, it is the neck and prominent parts of the wings. In horses, sarcomata have followed blows on the jaws; I have seen a sarcoma develop on the head of a cat after being struck with a stick; and in the case of an ox which broke its horn, a huge sarcomatous neoplasm subsequently developed from the stump. Careful examination of some of these cases seems to support the notion that after the injury the inflammatory tissue, or tissue of repair, exceeds normal limits, develops erratically, and plays the part of a tumour germ.

We must proceed to consider the second group of neoplasms, whose characteristic features are the following:—In addition to mesoblastic, they contain epithelial elements derived from either the epiblast or the hypoblast, and in their structure they more or less resemble glands. If the

Digitized by Google

resemblance is close, the neoplasm is termed an adenoma, and the cells clothe the alveoli in a regular manner; but if the cells are merely tumbled in confusion in the alveoli, it is called a carcinoma. It is necessary to discriminate between hyperplasia of a gland and a glandular neoplasm; the distinction is simple: the latter is impotent to produce the secretion normal to the gland. Another feature connecting carcinomata with the secreting glands is their relation to bloodvessels. The cells of which a gland is composed do not come directly in contact with the bloodvessels, but are separated from them by lymphatic spaces. It is well known that cancers are poorly supplied with blood, but contain an abundance of lymphatics. Further, cancers in their mode of development mimic glands. Glands commence by a down-growth of epithelium from the hypoblast or epiblast, as the case may be, into the deeper layers of the mesoblastic tissues beneath. This may be well seen in a section of a fœtal thumb at the fourth month of intra-uterine life. The sweat glands appear as little flask-shaped diverticula. This may be taken as a type of gland development generally. If, later in life, irritation, local or otherwise, affect the tissue, abnormal epithelial growths may occur, and, rising above the general level, produce a wart, or dipping into the sub-epithelial tissues, as in the early stage of gland development; but failing sufficient formative energy, either from decline of vigour or general constitutional debility, the new tissue never develops functionally, runs riot, and originates tissues of low vitality—carcinomata. Such in-growths may occur in the neighbourhood of any gland, mucous, sebaceous, mammary, and others, as diverticula from the acini; and according to the arrangement and variety of the cells and stroma, so we term them "epithelioma," "scirrhus," "encephaloid," and the like. There is no valid reason why these abnormal down-growths of epithelium should not be considered as tumour germs, in the same sense as the little masses of cartilage lodged in the interior of a long bone. It may be asked why should cancer be more frequent in the old or debilitated than in the young and vigorous? The answer is, young trees bring forth the best fruit because in them vigorous growth is at an acme; when this fades, then that which is inferior is produced. So with glands. Irritation in the young produces papillomata in the old cancer. This is not only true of man, but also of animals. Warts occur in the young, and cancer in the old ones. Cancer is, however, very rarely met with in animals other than man.

We must now consider the third group of neoplasms, which differ from the preceding groups in that their elements are derived from the three germinal layers, epiblastic, hypoblastic, and mesoblastic, or, as they were conveniently styled by Virchow, teratoid tumours. These neoplasms are always congenital, and are remarkable for the variety of elements composing them. They may contain fibrous tissue, bone, cartilage, muscle, skin, hair, nerves, glands, or indeed any tissue. Teratomata are especially liable to occur in those situations where the three blastodermic layers are brought into direct continuity with each other during fœtal life, but the connexion is only temporary. Critically examined, we shall find the positions of these temporary unions are often indicated by a passage which may exist for a longer or shorter period in the embryo. As a matter of fact, we get what I have been in the habit of calling an obsolete canal or passage. By this I mean canals which in the ancestors of mammals were functional, but they reapppear for a time in existing forms in obedience to the great law, heredity. As examples of obsolete canals we may take: (1) the curious recess at the top of the pharynx, which brings the infundibulum of the third ventricle into relation with the buccal involution; (2) the neurenteric passage, which brings the central canal of the cord and the alimentary canal into relation round the caudal end of the notochord; (3) the post-anal gut; (4) the branchial arches; and (5) the developmental history of testis, ovary, and Wolffian duct support the same view. Teratomata occurring in the sacral region are not a simple group, and Braune's observations long ago made us acquainted with the fact that some of the cystic forms are connected with the spinal canal and lie posterior to the coccyx, whilst others lie anterior to that structure. Braune also pointed out that the cystic teratomata connected with the spinal canal are due to dilatations of the spinal meninges—in fact, a spina bifida. Those anterior to the coccyx are, according to Braune, to be regarded as an abnormal growth of Luschka's glands, and other writers adopt this view. It is far more reasonable, however, to believe that these growths originate as abnormal dilatations of the post-anal gut—a section of the alimentary canal which for a certain period of embryonic life exists posterior to the anus in man and very many if not all vertebrata. The minute structure of this variety of teratomata agrees in every particular with the histological details of this section of the gut. With regard to the cystic sacral tumours connected with the meninges, it is not always that after birth the continuity of the cystic interior with the spinal canal can be made out, as in the following case reported by Virchow. A negro child a few days old presented a tumour on the left buttock to one side of the middle line. It was removed by a surgeon, Dr. Ludwig Wolff, in Central Africa, who believed it to be a lipoma. After examining the tumour, Virchow came to the conclusion that, notwithstanding its lateral situation, it was in reality a diverticulum from the spinal meninges. At the opposite end of the notochord we detect similar conditions. There may be a hernia of the spinal meninges through the floor of the sella turcica, or we may get a tumour containing skin, hair, nerves, muscle-fibre, and the like. In the neck, in association with the branchial arches, cysts arise, or in rarer cases tumours composed of complex elements. The same is equally true of the ovary and testis. They arise in connexion with the genital ridge, and at a certain period of their development are in intimate association with the peritoneal epithelium, and for a time are connected with it by a series of curious canals known to embryologists as the peritoneal funnels. In addition to this, the Wolffian duct at its commencement lies closely associated with the epiblast. Viewed in this light, I regard teratomata, not as a group of curiosities, but as a class of neoplasms full of interesting details. I regard them as arising from pre-existing tubules or ducts, which in the normal development should become obliterated, but they may in fœtal life dilate and become mixed with various other tissues in their immediate neighbourhood, and as they lie on the borderland of mesoblastic, epiblastic, and hypoblastic elements, they become incorporated with them, and form in many instances amorphous masses, and constitute one of the most powerful witnesses to Cohnheim's theory of "tumour germs." The relation of the teratoid tumours to obsolete canals is illustrated in a very striking manner in the tongue. Professor His has recently given a full account of the development of the tongue, and describes in detail the formation of a canal which runs from the foramen cæcum on the dorsum of the tongue downwards to the third branchial arch, and finally ends in the vesicle from which the middle portion of the thyroid gland takes origin. Later the canal is divided into two parts, due to the formation of the body of the hyoid bone. The one in connexion with the tongue is known as the lingual duct, and terminates in the hollow of the hyoid bone. It may occasionally be demonstrated in adult life, situated between the genio-hyo-glossi muscles. This situation is the favourite one for dermoid cysts. The lower portion of the duct, known as the thyroid duct, may sometimes be detected in those cases where we find a middle lobe to the thyroid body. It is extremely interesting to note that the structure and mode of development of the thyroid gland closely resemble those congenital coccygeal tumours lying anterior to the coccyx—e.g., (1) their association with the alimentary canal; (2) origin in a functionless tubule; (3) consisting of vesicles lined with cubical epithelium and bound together by cellular tissue.

Although not strictly tumours, yet possessing so much interest from the point of view of evolution, a few words must be said concerning congenital cervical cysts. These formations, as Mr. Thomas Smith has so well pointed out, all lie beneath the deep cervical fascia; they may be unilateral or involve the lateral and anterior regions of the neck, follow the deep fascia, and extend into the axilla, or, in rare cases, for a little distance into the mediastinum. Cases of this nature have been described and figured by Messrs. Birkett, Hutchinson, Smith, and Treves. In that the cyst extends at times into the axilla is of interest, for this circumstance first induced me to attempt the following explanation. In some of the lower animals, especially the chimpanzee and howling monkeys, a very large subfascial air sac connected with the larynx extends from the hyoid bone to the manubrium sterni, and laterally under the posterior triangles even into the axilla. The cysts in the human subject agree in anatomical details with the cervical sacs of the monkeys in such a striking manner that I am of opinion we have in these cysts repetitions of simian characters.

In conclusion, it seems impossible to escape from the

Digitized by Google

conviction that anyone ambitious of becoming a scientific pathologist must first be a sound human anatomist; he must also acquire a tolerable knowledge of comparative anatomy and keep well abreast of the teachings of embryology. Having acquired a competent knowledge in these subjects, he will then, in spite of himself, become a firm believer in the fundamental principles of the grand doctrine of "evolution."

Clinical Lecture
ON
CATARACT.

Delivered at the Eye Infirmary, Newcastle-on-Tyne.

BY C. S. JEAFFRESON, F.R.C.S. ED.,
SURGEON TO THE INFIRMARY.

GENTLEMEN,—This evening I purpose discussing the question of "Cataract and the operations for its relief." I need not say that the theme is one which is second to none in importance within the whole range of surgery, whether we look at it from its own intrinsic interest, or whether we consider the brilliant results which operative interference brings about in those who are the subject of this disease. An amputation or the resection of a joint may save or prolong life, but at best it leaves a deformed and mutilated organism, and this result is only attained at great risk to life and after great and prolonged physical suffering. A successful and well-executed cataract operation is practically painless. In a few days the wound is healed and the patient finds himself restored to all the blessings and joys which sight alone can afford him. Indeed, for many sight is only second to life itself, and there are not a few who would not care to live without it. There is something magical in this transition from darkness to light, and if the patient experiences pleasure and gratification which at times he can scarcely find words to express, the surgeon, as the indirect author of his pleasure, shares it equally with him. I know no feeling more gratifying and which inspires one with more legitimate conscious pride than that which occurs to us when, on taking the first peep at a case of cataract, we see a clear cornea and a dark untroubled pupil. The outline of objects first dawns upon the patient, gradually the image becomes more distinct, and when he realises that he sees once more his face illumines and he gives way to his joyful excitement. Equally bitter, on the other hand, is the feeling should disappointment meet us at each step of our examination, and no ray of light penetrates to cheer the hopeful and confiding sufferer; and doubly bitter will those feelings be if our inner consciousness remind us that perhaps the want of more care or more knowledge, or something left undone, has led to the untoward result. In operations, as in all other events in life, nothing tends more to eventual success than early disappointments, and if we take proper lessons from our failures our proportion of successes will steadily increase. If there is one thing more than another which characterises the surgery of the present day and has brought it to its pitch of perfection, it is the amount of personal care and attention the surgeon gives to each individual case, and if it is necessary in general surgery it is doubly so in ophthalmic surgery. A surgeon's success is generally in exact proportion to this element in the treatment, and you will all find—I see here speaking to the younger members present—that it is far more satisfactory, and in the end answers better in every way, to do a moderate amount of work thoroughly well than to do a large amount indifferently. I can only in this lecture attempt to give you a rough sketch of the matter in hand, for its full discussion would take many lectures; but to make matters clear I must refer briefly to the anatomy of the parts concerned.....

Now, gentlemen, as in the physiological state the lens and its capsule are absolutely transparent, so any opacity in one or the other is a pathological condition, and constitutes what we call a cataract—an objectionable name, we must allow, but one sanctioned by time, and which we must be content to adhere to. As there are necessarily many varieties of cataract, so there have sprung up many classifications; none of them are very complete, and some are not very scientific, and it is not till we have enumerated them all that you will appreciate the difficulties in the matter. In the first place, anatomical position has been taken as a basis, and we speak of lenticular and capsular cataract according as the opacity is situated in the lens or its capsule. Lenticular cataracts are cortical or nuclear according as the peripheral or central parts are affected; or, again, lamellar when only an intermediate layer between the nucleus and the cortex is opaque. Capsular cataracts, as we shall see by and bye, have no real existence, and depend upon changes in the layer of cells immediately below the capsule; these changes may take place in the anterior or posterior capsule, although in the posterior they are due to different causes. When close to the poles, they are called anterior and posterior polar cataracts; when the lens and capsule are both affected, we speak of capsulo-lenticular cataracts. When age forms a basis for classification, we speak of infantile, juvenile, and senile cataracts; when consistency, we speak of hard, soft, and cretaceous cataracts. Again, when we classify them in accordance with the conditions which have led to their development, we speak of traumatic, diabetic, senile, and secondary cataracts. By far the majority of cataracts which come under the notice of the surgeon are lenticular, and occur in elderly persons; and there are two ways in which they usually commence: the sclerosis or condensation or opacification which attends and is the essence of the disease commences either in the centre of the lens, when it is called nuclear, or attacks the peripheral parts of the cortex, when it is called cortical; although in the more advanced stages it is not always easy to say to which of these categories the cataract has chiefly belonged. At the commencement there is generally but little difficulty in deciding. The nuclear cataract occurring in the centre of the lens gives rise to ill-defined nebulous opacity, which sometimes produces more disturbance of vision than a superficial examination would lead us to expect. The cortical appear as star-like radii in the periphery; from their situation at the commencement they interfere comparatively little with vision, and even when advanced, in comparison with the nuclear, do not seem to impede the light so much. In my experience nuclear cataract occurs later in life than the cortical variety, which is certainly the more common of the two, and may be found in most of those cases in which the cataract, though undoubtedly senile, occurs at a comparatively early stage. Cortical and nuclear cataracts, gentlemen, form the majority of the cases which occur in old persons, or the so-called senile cataracts, but there are other forms of opacity affecting the lens substance. We have certain forms of cataract which may be called milky cataracts, in which the cortex does not follow the usual form of stellate degeneration, but breaks down somewhat rapidly and equably in all its parts; it may and does not infrequently pass into a fluid state, in which case the nucleus floats free in it, and we have what is termed a Morgagnian cataract. This usually occurs at a less advanced period of life than senile cataract, and is sometimes a monocular affection. Again, we have another form of lenticular cataract which is called the laminar or lamellar, which consists of an opacification of certain layers of the lens, leaving its nucleus and peripheral parts transparent. This is always a congenital form of cataract, though by no means the only one. Capsular cataracts may occur in connexion with cortical or lenticular cataract as a senile change, but it is not usually till a late stage that the intra-capsular cells become affected. Sometimes, however, the opacity commences in this situation, usually in persons of middle age, and who are the subjects of inherited cataracteous tendencies. At the close of the lecture I hope to show you a case of this kind, in which numerous punctated opacities occupy the anterior surface of the lens within the capsule. One of the most common forms of capsular cataract is what is called the pyramidal or anterior polar cataract, because it occurs at the anterior pole of the lens. It is usually the result of purulent ophthalmia in early life, which, having led to a small central ulcer of the cornea and consequent loss of aqueous fluid, has caused the lens to project against and touch the posterior surface of the cornea, where it contracts adhesions blocking up the base of the ulcer. This allows the aqueous humour again to accumulate, leading to a detachment of the lens, which resumes once more its proper position, but leaving at the spot where it was in contact with the cornea a patch of inflammatory

Digitized by Google

exudation, which has sometimes a pyramidal form when viewed in profile. Iritis sometimes leads to capsular cataract by depositing inflammatory lymph on the surface of the capsule. Changes somewhat analogous to those which take place in the intra-capsular cells of the anterior portion of the capsule sometimes occur in the posterior pole, and we have then a posterior polar cataract. This is usually the result of inflammatory exudation from the anterior surface of the hyaloid covering of the vitreous. I shall refer later on to these opacities. The capsular opacities which are the common result of operations are really not capsular, but are usually the result of inflammatory exudation coating small portions of lenticular matter which have failed to escape with the rest of the lens at the time of operating.

These, then, gentlemen, are the chief forms of cataract met with in practice, although there are some rarer forms, notably what is called black cataract, the pathology of which is still somewhat obscure, but in which the lens assumes a very dark amber colour, approaching almost to black, and which by some is supposed to be due to the absorption of hæmatine. As you are well aware, certain constitutional conditions predispose to cataract. It frequently occurs in glycosuria, occasionally in albuminuria, and where there is a tendency to atheromatous arterial degeneration. In these cases the lens usually breaks down more rapidly than in ordinary cases of senile cataract. Traumatic cataracts are usually the result of some rupture of the capsule which allows access of the aqueous humour to the lens fibres. The rapidity with which they develop depends chiefly upon the size of the wound, partly upon the age of the patient, and other circumstances. Cataractous opacity may follow blows upon the eye or orbit, without any evidence of rupture of the capsule; in these cases the nutrition of the lens is impaired by the concussion either through some disturbance in the choroid and ciliary processes or nervous reflex influence.

The causes of cataract are still to a great extent wrapped in obscurity. In many senile cases the changes may be looked upon as one of the expressions of tissue degeneration which are common in advanced life. We know how the skin loses its elasticity and wrinkles, and how the hair turns grey and falls off. The lens in embryonic life is developed from the epidermic layer of the blastoderm, and it shares the life history of the original structures from which it grew. Although we are not fully acquainted with the method of its nutrition, we know it must be carried on through the medium of the fluids which surround it, and that anything which impedes the due circulation of these fluids and the blood-supply from which they are derived must react upon the lens. In this way there can be no doubt the secondary cataracts of glaucoma and some inflammatory affections are produced. And it is probably from some change in the density of the media that surrounds the lens that diabetic cataract results. It is perhaps too, in this way, by disturbing the balance of endosmose and exosmose, that those persons are more prone to cataract whose face and eyes are constantly being exposed to high temperatures combined with brilliant illumination—such as bottle-makers, blacksmiths, furnace-men, &c. The former trade has a special tendency to produce cataract, which is well known to the men, and has furnished me with many cases.

Now, gentlemen, I come to the more practical part of the question—What are the symptoms, objective and subjective, of cataract? With what is the diagnosis likely to be confounded? Speaking now of ordinary senile cataract, age is the first point which attracts our attention. Degeneration of the lens-tissue as the result of uncomplicated senile changes is rare before forty-five years of age, although it may occasionally occur earlier, especially if there is, as is not unfrequently the case, an inherited tendency to the disease. I have at present under my care an old lady seventy years of age who suffers from senile cataract; two of her daughters, one thirty-nine the other forty-one, each suffers from incipient but well-marked cataracts. Again, some years ago, an elderly gentleman was under my care who suffered from cataract, his brother was the subject of the same disease, and two of his brother's sons, aged thirty-nine and forty-one, were both similarly afflicted. There can be no doubt, then, that it is a malady which shows strong hereditary tendencies. Well, then, gentlemen, when a patient advanced in years comes to you and complains of failing vision, especially for distant objects, the symptoms being unaccompanied by pain in the eye or head, and there having been no history of any kind of inflammatory affection, your first suspicion will be of cataract. Your suspicions will be materially increased if the patient complains of seeing worse on a bright day, and better towards twilight and dusk. If you give him type to read, he will probably turn his back to the window and try to assist himself by shading his eye with his hand. He may complain of halos round lights or of their looking distorted or drawn out, perhaps even of monocular polyopia. It may seem superfluous to explain the *rationale* of these symptoms, because some of them are obvious. The bright light contracts the pupil, leaving a comparatively small opening in an already hazy lens. In nuclear opacity, therefore, the sight will be much interfered with, as it occupies the part of the lens opposite the pupil; in cortical cataract much less so, as only the peripheral parts are affected; in some cases a contracted pupil may even help sight. The distortion of lights and halos is produced by changes in the refrangibility of the lens, the result of alteration in its density; and the polyopia is the result of transparent passages being left in the cataractous lens, each such passage producing a faint image of its own. Although advanced cataract can generally be diagnosed objectively at once without difficulty, in the earlier stages it is not always so easily detected. Where there is doubt use should be made of oblique illumination, and in still more doubtful cases the pupil should be dilated with atropine. In this way we shall be able to clear up all doubts as to the nature, condition, situation, and probable rate of development of the cataract. This method of examination, together with the use of the ophthalmoscopic mirror, will further enable us to determine if the cataract is complicated with other diseased conditions, a point of much importance when the advisability of an operation is in view. At an early part of this lecture I stated how at first sight the greenish-grey appearance of the lens, which is natural in advanced life and is more marked in some diseased conditions, might be mistaken for cataract. Oblique illumination dispels any doubt in these cases, and the clear red reflex from the fundus when the ophthalmoscopic mirror is used confirms this proof. Patches of opacity in the lens, when viewed by the mirror alone, appear as dark objects with the red reflex of the fundus as a background. This phenomenon, which is clear and unmistakable, is owing to the reflection of light from the fundus being obstructed. It occurs equally with opacities in the vitreous chamber, but these are not, when care is taken and oblique illumination used, very liable to be mistaken for opacities in the lens. Indeed there are few or no maladies which can easily be mistaken for cataract when proper precautions are used; but cataract is so frequently complicated with other conditions, and these may play such an important part in lowering vision and influencing the prospects of an operation as to deserve our greatest attention. Lenticular opacity is liable to occur in glaucoma, in iritis after synechia have taken place, in high degrees of myopia, after detachment of the retina, in the final stages of retinitis pigmentosa, and other conditions. I may perhaps best clear up the difficulties which beset the diagnosis of a case of cataract by stating the symptoms we should expect to be present in an uncomplicated case, and afterwards referring to the inferences which may be drawn from any departure from these lines. In an ordinary case of uncomplicated cataract, the result of senile changes only, we should expect, first, that there should be an absence of any signs of diabetes, albuminuria, or other blood contamination. Locally there should be a well-defined round and active pupil, both to direct and indirect stimulation. The loss of sight should be only in proportion to the visible opacity in the lens. This is a symptom which it is difficult to estimate without considerable experience, as it is liable to much variation. The field of vision should have undergone no diminution of its area. The tension of the eye should be the subject of the most careful examination, and any hyper-tonicity should lead to a minute investigation of the early symptoms and history of the disease. When a case of cataract, gentlemen, presents all these favourable symptoms, we may look hopefully to a successful issue, but any departure from them, however slight, should make us give a guarded prognosis. To some of these points I shall, however, refer again.

(To be continued.)

HOSPITAL SUNDAY in Leeds was held on the 21st inst., when collections were made in the various churches and chapels of the town and district.

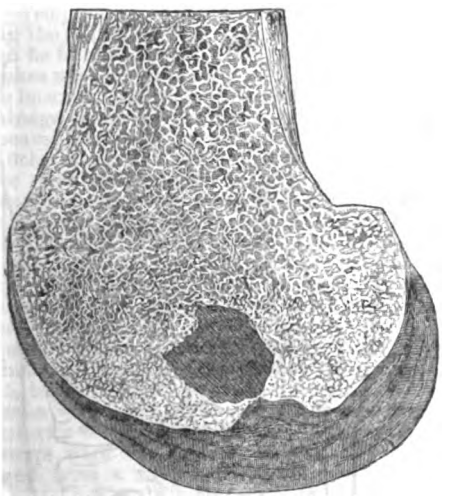
TWO CASES OF



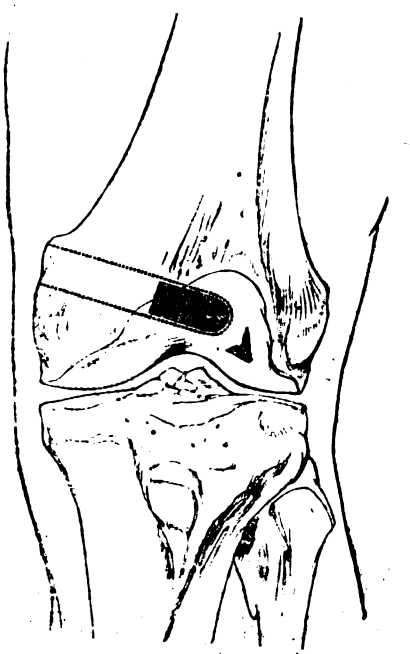
GUNSHOT INJURY IN THE NEIGHBOURHOOD OF THE KNEE-JOINT,

WITH LODGMENT OF THE PROJECTILE IN THE CONDYLES OF THE FEMUR.

BY SIR WILLIAM MAC CORMAC.

THE interesting case reported by Dr. MacGillivray in THE LANCET of December 12th, 1885, where he successfully removed half an Enfield bullet which had remained lodged in the internal condyle of the femur for thirty years, and Professor Longmore's valuable comments thereon in THE LANCET of January 2nd, 1886, induce me to publish notes of two cases recently under my care, in each of which a bullet had remained for some time lodged in the condyles of the femur. Dr. MacGillivray's case illustrates the fact that a bullet lodged in bone is apt to produce mischief sooner or later, and that after even protracted intervals of quiescence inflammation recurs, abscess forms around the bullet, and adjacent structures may become seriously implicated. This happened notably in one instance under my own observation, where a man who had been shot in the

FIG. 1.



Section of femur, showing a bullet which had lodged in the condyles for fifteen years.

sacrum during the first New Zealand war suffered at intervals great pain and distress from abscess and exfoliation of bone. The bullet could not be felt at the time, and it was not till an interval of thirty years had elapsed that the ball was discovered and extracted, the patient subsequently making an excellent recovery. This course I believe to be the rule in such cases; but the converse may occur, and of this a typical instance is recorded in the third volume of the "Surgical History of the War of the Rebellion," p. 372. Lieutenant Blake, aged twenty-five years, was wounded at Antietam in 1861, while kneeling to stop bleeding from a comrade, by a shot which, after traversing the elbow, entered the outer side of the left knee-joint. On examination the probe is stated to have freely entered the cavity of the joint, but no bullet could be found. He was sent to Boston, where he came under the care of Dr. Mason Warren. Both the knee and elbow-joints did perfectly well, and after two months the patient could get about. He recovered the movement of both joints, and could walk without any sign of lameness, the ball still remaining in the knee. He continued actively engaged in his business, suffering no kind of inconvenience until fifteen years later, when he was attacked with pneumonia, of which he died, the bullet having remained harmlessly in the outer condyle all this time. A necropsy was made, and I saw the specimen thus obtained in the Army Medical Museum at Washington. It is a most curious one. The ball is seen in the section completely fixed in the bone, without a trace of inflammatory disturbance about it. The bone is everywhere in direct contact with the bullet. There is no layer of granulation tissue or cavity. The articular cartilage covering the end of the femur is quite smooth and unchanged, except just over the bullet, where there is a cicatricial depression. At this point the bullet is not more than a line distant from the surface. (Fig. 1.)

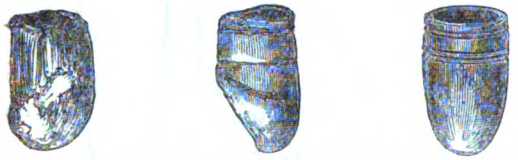
The notes of the two cases following were taken by Mr. H. Duncan and Mr. E. Solly, and to the latter I am indebted for the admirable drawings showing the position of the bullet in each case, as well as for the drawings of the bullets themselves.

CASE 1. *Gunshot-wound of the condyles of the left femur.*—Arthur A——, aged thirty, an ex-officer in the French army, was admitted into St. Thomas's Hospital on June 4th, 1885, and discharged on June 26th. On Dec. 23rd, 1884, the patient received a bullet-wound from a Martini-Henry rifle on the inner side of the left thigh, just above the knee. He says it was fired from a distance of about eighty or ninety yards. He was out, he told us, with a French comrade on a hunting expedition in Senegal, on the West Coast of Africa, collecting wild animals to send to Europe for the Zoological Gardens. On one occasion they came unawares upon a lion, and the Frenchman, it seems, fired too soon from excitement, and shot A. A——, instead of the lion. He felt a "dull thud" on the inner side of the knee; blood escaped freely, which he tried to staunch, while his black servants went for help.

FIG. 2.

Lower end of left femur. The length and direction of the bullet track and the position of the bullet are indicated.

A doctor arrived, who, after probing the wound, declared the bullet must have fallen out, and the next day after the accident he was carried to the French military hospital at St. Louis, on the coast, and remained there from Dec. 24th, 1884, to May 4th, 1885. While in the hospital the knee became much swollen, he suffered great pain in it, and had several attacks of fever, the temperature rising, he stated, to 105°. A wire splint was applied. The wound continued to discharge freely. The knee became flexed and fixed, and continued very painful and swollen. From all this the joint would certainly appear to have been implicated. The wound was many times probed, and an exploratory incision was also made, but the bullet could never be detected, the surgeons declaring there was no bullet in the limb. Finally, the man was told that in order to save his life it would be necessary to amputate the limb. Fearing to have it done on the spot, he decided, contrary to the advice of the doctors, to sail for home, and came over to England in May, being admitted into St. Thomas's Hospital on June 4th. During the voyage home he greatly improved in general health.



On admission, a sinus was found opening just above the

Digitized by Google

internal condyle of the left femur, a probe, passed about two inches downwards and outwards across the condyles, tending towards the cavity of the knee-joint. The knee was quite stiff, and the parts around it swollen. He did not complain of pain, except on movement. In accordance with what he had been told when he left the African coast, he came to the hospital fully prepared to have his thigh amputated. I probed the sinus, and detected a body which I believed to be the bullet. (Fig. 2.) A Nélaton's porcelain probe was then passed in, and on withdrawal was found to be distinctly marked with lead.

June 6th.—Ether was administered, and, an Esmarch bandage having been applied, a director was passed into the sinus and an incision made down to the bone, the opening in which was sufficiently enlarged with the mallet and chisel. After some difficulty the bullet was then seized with a pair of toothed bullet forceps and extracted. A drainage-tube was inserted, and the wound, having been washed out, was dressed antiseptically with iodoform gauze. The dressings were applied before the compression was taken off, and on removal of the Esmarch tourniquet a considerable amount of bleeding took place, which soaked through the dressings and necessitated the opening up of the wound, which was then packed and fresh dressings applied. The limb was put up in a long outside splint, a MacIntyre not having been got ready. The bullet, of which a drawing is given (Fig. 3), weighed 194 gr., was about $\frac{11}{16}$ in. long and $\frac{7}{16}$ in. in diameter. It presents longitudinal striæ, such as might be caused by its passage down a rifle-barrel, but is otherwise comparatively little changed in shape. It is not nearly so large as the ordinary bullet for a Martini-Henry rifle. In Fig. 4 the bullet extracted in the second

FIG. 3. FIG. 4. FIG. 5.

Bullets removed in the cases of A. A—— and R. L——, together with a similar ball from an unexploded cartridge.

case, very much resembling that from the first, is represented; and in Fig. 5 a similar ball from an unused cartridge.

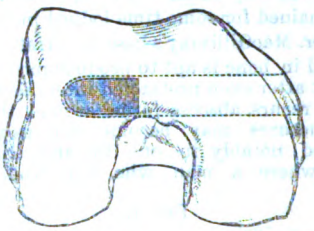
7th.—Patient very comfortable. The long outside splint changed for a MacIntyre. From this date he progressed perfectly favourably till June 24th, when he was discharged with a small sinus, still unclosed, in the track of the bullet. Passive movements had been resorted to and the motion of the joint gradually improved. On his discharge he could flex it nearly to a right angle.

Arthur A—— was again admitted for a short time on Oct. 3rd. The sinus in the track of the bullet persisted. This was opened up, but no dead bone discovered, and the patient was again discharged on Nov. 17th, the sinus being then almost closed. On the 12th of January last I had an opportunity of again seeing my former patient. The movements of the joint were practically perfect, the sinus was closed, he suffered no pain or inconvenience, and could walk long distances without fatigue. He was, in short, perfectly well; he had married since he left the hospital, and intended to sail for Australia the following day.

CASE 2. *Gunshot wound of the condyles of the right femur.*—R. L——, aged twenty-five, a brother of one of my dressers, served as a gentleman trooper in Methuen's Horse during the late Bechuanaland expedition. On the afternoon of Sept. 11th, 1885, while sitting in his tent at dinner, with a mess-tin between his knees, a service revolver was accidentally discharged at a distance of about four or five feet, the bullet, weighing 240 grs., and measuring $\frac{3}{4}$ in. by $\frac{7}{16}$ in., having previously traversed the mess-tin, entered just above the right knee on the inner side, close to the adductor tubercle, and passed almost directly outwards. (See Figs. 6 and 7.) The patient was conveyed four or five miles in a "mealy" waggon to the hospital, keeping his knee flexed in the same position as at the time of the accident. He describes the pain felt at the moment of injury as resembling that which would be caused by a blow on the knee from a mallet. The amount of blood lost at the time or subsequently was but slight. On examination, however, soon after, by a surgeon, no foreign body could be felt, and neither pieces of clothing nor the bullet were discovered. The limb was placed in a splint, and dressed daily with carbolised oil and lint. The temperature was only once taken after the accident, when it was 101°. Two or three days afterwards the knee became swollen and very painful. The discharge was described as at first thin and red, subsequently it became whitish yellow. The patient was after a time conveyed to Cape Town, where he arrived on Oct. 3rd, and the next day he sailed for England, which he reached on Oct. 28th.

He was admitted into St. Thomas's Home on October 31st, and was next day examined by me. There was a sinus over the right internal condyle, discharging a small quantity of thin pus. The probe could be passed almost directly outwards, with a slightly downward direction, for nearly three

FIG. 6.



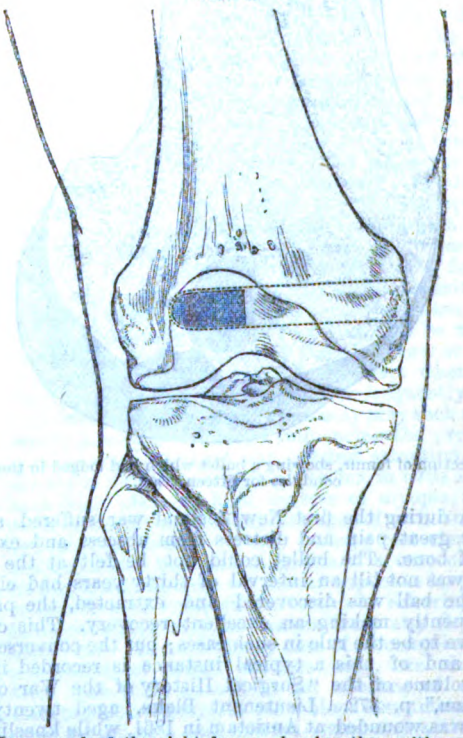


FIG. 7.

Lower end of the right femur, showing the position and direction of the bullet track in Case 2. (Half the natural size.)

inches. At the bottom the dull sensation of striking a bullet could be felt, and on introducing a Nélaton's probe the porcelain came out distinctly marked with the lead stain. There could be no doubt that the projectile was lodged in the external condyle of the femur, very close to its articular surface. The patella was movable, but the knee was painful, could only be very slightly bent, and the soft parts around the joint were infiltrated.

Nov. 2nd.—Ether having been administered and Esmarch's apparatus applied, I again introduced into the sinus a Nélaton's probe, and the porcelain on withdrawal was plainly seen to be streaked with lead. A vertical incision was then made over the posterior and inner aspect of the condyle for about 2½ in., having the wound in its centre, and extending down to the bone. From this the soft parts and periosteum

Digitized by Google

were detached for about an inch around the opening made by the ball, which was then enlarged by the chisel and some pieces of bone removed. The projectile was now found firmly fixed in the cancellous tissue. By means of a pair of toothed forceps the bullet was speedily seized and withdrawn. A probe could now be passed into the interior of the bone for a distance of exactly 2½ in. from its surface, and the extremity must have reached nearly to the external aspect of the external condyle, while the bullet track could certainly not have been, at all events in some parts of its course, more than a quarter of an inch distant from the articular surface of the end of the femur. A double drainage-tube having been introduced, the wound was syringed out with carbolic acid solution of a strength of 1 in 40. The edges of the divided tissues were brought together by silk sutures, and the wound dressed with iodoform gauze and salicylic wool. A narrow wooden splint curved to the shape of the limb was applied posteriorly, and strips of Bavarian flannel soaked in plaster-of-Paris were applied anteriorly and laterally, the limb being bandaged to the splint from the foot to about half-way up the thigh.

3rd.—The patient has had a good night. Last evening's temperature was 100·8°, and this morning it is 100·4°. A slight oozing came through last night and a fresh dressing was applied.

4th.—Temperature last night 100·8°; this morning 99·6°. Wound dressed. It is looking healthy. New plaster-of-Paris splints were applied, and the wooden one was removed.

11th.—Temperature last night 100·2°; this morning 99°.

During the next week the patient did not complain of any pain, and he felt quite well. The temperature was normal. The stitches were removed on the 8th, when the wound was found to be united except in the position of the former sinus. The drainage-tube was gradually shortened as the bullet-track became filled with granulations. The patient got up on the 16th. From first to last he had little or no inconvenience. The joint under the influence of passive movements was becoming less swollen and supple, and he left for home on Nov. 28th, able to walk a long distance without the least difficulty. The sinus was quite superficial and on the point of closing. In a letter from Mr. L——, dated Jan. 14th, 1886, he says: "I can do as much walking and riding now as I ever did, and bend my right leg as far as the other." The bullet, of which a drawing is given in Fig. 4, was flattened somewhat at its extremity; it weighed 340 grains. A similar bullet, weighing 245 grains, is shown in Fig. 5, taken from an unexploded cartridge.

Remarks.—The two cases recorded are striking from the similarity of the injury in each. The bullets causing the damage were almost alike in size, although one was discharged from a rifle and the other at close quarters from a pistol. The ball traversed the expanded portion of the condyles transversely in both cases from within outwards, in each instance very near to the articular surface, lodging in the bone in both, and in both remaining undiscovered for a considerable time. In both, too, there were symptoms of inflammation in the knee-joint, some pain, fever, swelling, and subsequent stiffness, which passed off. It is difficult to believe that in either the injury could have been wholly extra-articular. Conical bullets such as these, and capable of penetrating the bone to so considerable a depth, would be very likely to cause fissures which would almost certainly extend to the joint surface, while the continued presence of the foreign body could scarcely fail, one would suppose, to excite articular mischief. Nevertheless, in neither of these two cases has any permanent ill result followed, and the function of the joint is in both perfectly restored. There is a strong presumption, without, I admit, any positive proof, that the knee-joint was implicated to a greater or less degree in each of these cases, yet recovery has ensued with a freely movable articulation, and certainly without in either case any special advantage in regard to treatment. Perhaps, after all, a gunshot injury of the knee may not be always so disastrous as it was at one time assumed to be. Langenbeck told me he had met with at least one hundred cases of penetrating wound of the knee-joint followed by recovery during the Franco-German war. Many cases of recovery after a bullet had traversed the joint and fractured the bones are recorded by the Surgeon-General of the United States army; and then there are the remarkable results published by Bergmann and Reyher obtained after antiseptic occlusion in the Russo-Turkish and other campaigns. During the American war 338 cases of unmistakable fracture involving the bones of the knee-joint made good recoveries after an altogether expectant plan of treatment—that is, both life and limb were preserved. Many of the cases besides the one which I have first quoted, are most remarkable, but for the details I must refer to the Surgeon-General's report. A conservative treatment, whenever it is possible to adopt it, is probably by far the most promising one for gunshot injury of the knee-joint, and it has proved the most successful, especially in recent campaigns. Excision of the knee for gunshot injury in time of war has hitherto been disastrous, while amputation has been very fatal also.

SYMMETRICAL SYNOVITIS OF THE KNEE IN HEREDITARY SYPHILIS.

By H. H. CLUTTON,
ASSISTANT-SURGEON TO ST. THOMAS'S HOSPITAL.

THE fact that the condition of which the title of this paper gives the most prominent feature has been little noticed in our surgical literature tempts me to make a few remarks as to its clinical features. I have myself but little doubt that it is due to hereditary syphilis, for the subjects of this symmetrical synovitis who have come under my observation have always given other evidence, either past or present, of the disease. My own cases, of which the notes have been carefully kept, are seven in number. Mr. Nettleship, who has also taken a great interest in these cases, has kindly given me the notes of three others, which I have myself seen at the time they were under observation in the eye department at St. Thomas's Hospital. Mr. Lawford has also supplied me with another case during the last six months, which brings the total to eleven. I have, I am sure, seen many more of which I can find no accurate record; and I well remember, some years ago, soon after I began to take an interest in this subject, that Dr. Greenfield, who was then my colleague, drew my attention to several cases which had occurred in his practice. It must be remembered that my own cases were all out-patients, one or two only being admitted for a time to test the efficacy of splints and rest. The difficulty of keeping any notes in the out-patient room must be my excuse for this deficiency. The disease is, I am sure, a rare one, so that only a few cases will come under the observation of any one surgeon; for since my attention has been directed to this condition I have been on the look out for such patients, and have only met with quite a small number.

The average age of the patients recorded in the accompanying table was about thirteen, but they were mostly between the ages of eight and fifteen. The predominant features of the disease were the symmetry of the affection, the freedom from pain, the long duration of the symptoms, and the free mobility of the joints on passive movement throughout the course of the disease. Its symmetrical character first led me to look for a constitutional cause, and there was no difficulty in seeing that the patients were the subjects of hereditary syphilis. I do not mean to say that no other constitutional diseases could possibly have produced such a symmetrical condition, but I do think that other joints besides the knees would probably have been at some time and in some of the cases affected in a similar manner if such diseases as rheumatism, gonorrhœa, or gout had been the cause. I have never seen both knee-joints fill with fluid, causing scarcely any pain or discomfort, whilst other joints remain quite free from any signs of inflammation, except in cases where there was distinct evidence, either past or present, of hereditary syphilis. The patient generally complains of stiffness in one knee, which is then found full of fluid, but not tense: on careful examination the other knee is also found to contain fluid, but not to the same extent as the one for which advice is sought. So that it is fair to assume that the knee to which attention has been directed by the patient has been affected some little time before he has felt any inconvenience. In a few instances there has been an interval of some months before the second knee has given the ordinary signs of synovitis; and in one case (No. 5 in table), which was that of the patient aged twenty, there was an interval of two years. All the other joints have been at the same time carefully examined, to make

Digitized by Google

sure that such an insidious chronic synovitis has not been overlooked, but no joint affection could at any time be discovered elsewhere; nor was there any history pointing in that direction in any of the cases which are here recorded, except in No. 11 in the table. The swelling in some of the cases was accompanied by considerable thickening of the synovial membrane; and in one instance (No. 8) recorded by Mr. Nettleship, the observation is made that in some places it gave the "impression of loose bodies in the joint." But in the greater number this swollen condition was not so noticeable a feature as in the synovitis which may occur as one of the later manifestations of the acquired disease. The chief part of the swelling in the cases now under consideration seemed to be produced by an increased quantity of synovial fluid. The joints were never tense, but gave a sensation of flaccid fluctuation, as if they were only half full of fluid. The bones in the immediate neighbourhood were not enlarged, and in only a small proportion of the cases was there any articular tenderness. Nodes were occasionally found, but generally some little time after the onset of the swollen joint and at some little distance from the affected articulation. The peculiarly chronic nature of the synovitis is still further shown by the fact that in all the cases referred to in this paper the swelling has remained with scarcely any alteration for from three to six months, and in one instance for twelve months. In one case (No. 10) the symptoms followed a more acute course, but were distinctly attributed to a fall on the knees a week previously to the admission of the patient. Treatment by splints and rest in bed seemed to influence the course of the disease very slightly, for those that were treated in this way were as slow in getting well as those that had no local treatment whatever, for as soon as the splints were removed the effusion returned. The ultimate result in all the cases that came under my observation was the perfect recovery of the joints, the most important part of the treatment appearing to be the exhibition of anti-syphilitic remedies—mercury and iodide of potassium; but these drugs had not the same marked effect that they have in the acquired disease.

The facts as to hereditary syphilis are as follows. Of the eleven cases, active keratitis was present in nine, and in one other the cornea bore traces of a former attack, so that in only one had the cornea escaped. Five had the central incisors marked in the manner characteristic of the disease. Four had nodes on the tibiæ, and two were afflicted with absolute deafness of recent origin. The latter symptom was in each case devoid of any other obvious cause, and must, I think, be attributed to hereditary syphilis. Thus, every one of the cases quoted had two or more of the symptoms which, taken together, may be fairly held to establish the presence of the disease in question. Less reliable symptoms, such as those presented by the features, have not been mentioned; but they existed in most of the children who came to the out-patient room with symmetrical synovitis of the knee. The family history is proverbially difficult to obtain in this department of the hospital, and although in a few instances it tended to confirm the opinion already formed, it may be stated generally to have been of a negative character. I do not think that this disease has any relation to epiphysitis, which is so common in syphilitic infants, for there was no apparent enlargement of the bone, as has been already stated, and the swelling was quite uniform in outline. In epiphysitis the swelling is always more or less unilateral, for although the whole joint may be enlarged by consecutive synovitis, one side will generally be found larger than the other, with increased tenderness on the side affected; whereas in the symmetrical synovitis, to which allusion is here made, the joint is uniformly enlarged, and the synovial membrane appears to be the only part affected.

ELEVEN CASES OF SYMMETRICAL SYNOVITIS OF THE KNEE.

No.	Sex.	Age.	Joints.	Duration of symptoms.	Evidence of hereditary syphilis.	Family history.
1	M.	10	Both knees.	4 months.	Double interstitial keratitis; typical teeth; ostitis of both tibiæ.	No notes.
2	F.	8	Both knees.	6 months.	Double interstitial keratitis; ostitis of one tibia.	No history.
3	M.	11	Both knees.	6 weeks, and then ceased attending.	One typical central incisor; nodes on tibiæ; snuffles and skin eruptions in infancy.	Mother had two stillborn children before patient.
4	F.	9	Both knees.	3 months.	Interstitial keratitis of one eye of two weeks' standing, with no further notes; one typical central incisor.	No history.
5	F.	20	Both knees (two years apart).	6 months each.	Remains of double interstitial keratitis; ostitis of both tibiæ, which are very large.	No history.
6	F.	10	Both knees.	7 months.	Double interstitial keratitis; typical teeth.	Father syphilitic; no evidence in family beyond patient.
7	F.	15	Both knees, and right articular tenderness.	6 months.	Double interstitial keratitis under Mr. Nettleship; incurable deafness of one month's standing.	No history.
8	M.	14	Both knees, articular tenderness.	3 months.	Interstitial keratitis; typical teeth; deaf.	No notes.
9	M.	12	Both knees.	2 months, and probably more.	Interstitial keratitis.	Well-marked history of mother being infected, and then having miscarriages.
10	F.	8	Both knees acute and painful one week after fall on knees. One joint tapped. Recovered with good joints.	4 months.	Double interstitial keratitis.	Doubtful history.
11	M.	21	Both knees. History also of both ankles having been swollen at commencement.	12 months.	Double interstitial keratitis for nine months; still under observation.	Patient is third child; fourth, fifth, sixth, and seventh children died in infancy; eighth under observation for interstitial keratitis.

To recapitulate in a few words the principal features of the condition which was demonstrated by these few cases, one would say that the synovitis was symmetrical, affecting only the knees, that was of a chronic and painless character, and that all the patients were the subjects of hereditary syphilis. I can offer no satisfactory explanation of the facts here recorded, but must content myself with drawing attention to a few clinical symptoms. At the same time I would like to point out that if the condition which is now under consideration be really due to hereditary syphilis, the similarity between interstitial keratitis and this symmetrical synovitis is so marked as scarcely to require any lengthened explanation. Both knees, like the eyes, are, in my experience, sooner or later affected, and often with an interval between the commencement of the symptoms in each joint. Both diseases are exceedingly chronic, and produce little or no destructive changes in the tissues involved, neither suppuration nor adhesions having occurred in any of the cases that came under my observation. They are also both liable to relapses, and not very amenable to treatment. The age of the patients is another and striking point of similarity, for

Digitized by Google

seven out of the eleven were between eight and twelve years of age. In two cases the symptoms arose at a much later date, but this also occurs in interstitial keratitis, so that even in its rarer forms it corresponds with that disease in this particular—that of the age of the patient. I am at a loss to explain why the knees should be affected in preference to other joints. It is probable that, with further observation, the knees will not be found to occupy this solitary distinction, and that other joints will be seen to be affected in a similar manner. But up to the present time I have not seen this chronic symmetrical synovitis, which appears to be associated with hereditary syphilis, in any other joints besides the knees. That it should be symmetrical is only what one expects from our knowledge of the similar manifestations of the disease at this period of life.

THE NEUROTIC TREATMENT OF CATARRH.[1]

BY DAVID B. LEES, M.A., M.D., F.R.C.P.,
PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL; ASSISTANT-PHYSICIAN, HOSPITAL FOR SICK CHILDREN.

ALTHOUGH by some writers the meaning of the word "catarrh" is extended to include various affections which are believed to have similar origin, the term is in itself simply a word-picture of that familiar complaint which the Greeks called "coryza," and which we know as a "cold in the head." Too familiar to most of us is this annoying condition. A severe cold hinders effective work for several days, makes the sufferer miserable while it lasts, depresses his vital energy, and sours his temper; it leaves him with an increased predisposition to take cold again. Nor is this all; it is too often the starting-point of chronic or even of acute disease. A formidable list might be made out of the sequelæ of catarrh; it would include chronic pharyngitis and enlarged tonsils, deafness from Eustachian obstruction and altered conditions of the tympanic membrane, muco-purulent collections in the middle ear, and in infants posterior basic meningitis leading to death or idiocy, chronic laryngitis with hoarseness, chronic bronchitis, and in neurotic subjects asthma, and last, but not least, through the permitted invasion of the tubercle bacillus, phthisis.

The present treatment of catarrh cannot be considered satisfactory. It rarely succeeds in cutting short the malady or in alleviating to any great extent its discomforts. It is essentially a diaphoretic treatment, insisting on confinement in warmed rooms, swallowing of hot liquids, and use of hot-water or vapour baths, or of the Turkish bath. The result aimed at by these various measures is diaphoresis; in plain English, the object is to arrest the flow from the nose by causing a flow from the skin. The reasonableness of this is about on a par with the action of one who should seek to have all the street lamps lighted in order to check the flow of gas into his house from a leak in his pipes; the plan might to some extent be successful, but we should not think highly of its wisdom, and should ask whether the tap had been turned at the meter. Can we in any way directly arrest the flow in catarrh? The answer to this depends upon a clear understanding as to its nature. If we ask the question, "What is catarrh essentially?" we must reply, "Catarrh is a neurosis, in which the vaso-motor system is largely concerned."

Nothing can be regarded as more certain than that the onset of catarrh is due, in a very large number of cases, to an impression of cold on the surface of the body, owing to draughts, insufficient clothing, or the chilling evaporation from damp clothes. An impression is made upon the cutaneous nerves, and is by them transmitted to the nerve centres. The effect is not immediately manifested, but after a few hours a general chilliness of the surface is experienced, clearly due to a general vaso-motor spasm of the cutaneous vessels, and accompanied by flying pains and aches in the limbs, which are probably really central and not peripheral, and due to disturbed vascular conditions of the nerve-centres themselves: at all events, a full dose of bromide very rapidly puts an end to them. At first the vessels of the nose, throat, and air-passages share in the spasm, and for a while the throat feels dry from the diminished secretion. But before long these vessels pass from a condition of spasm into a condition of paralytic dilatation, and then commences the flux of liquid, copious and clear at first, but gradually growing more opaque as cellular elements become mixed with it, and finally diminishing. In catarrh primarily nasal the affected arteries are the terminal branches of the internal maxillary, the nasal or sphenopalatine, which supply the mucous membrane of the nose. Other offshoots of this artery may also be affected, and it is probable that the acute earache which is so common in young children in the early stage of a catarrh, long before any effects of Eustachian obstruction are manifested, is due to a tense hyperæmia of the drum membrane resulting from a paralytic dilatation of the tympanic branch of the internal maxillary. Nor is the congestion limited to this artery and its subdivisions; it may spread to other branches of the external carotid, and the facial may be felt forcibly beating. One consequence of the dilatation of the nasal branches of the internal maxillary is congestion of the highly vascular mucous membrane covering the inferior turbinated bones, the result of which is the production of a condition of extreme hyperæsthesia of this part, expressing itself partly by local sensations of tingling, and partly by the reflex neurosis known as "sneezing." The hyperæsthesia is often so great that a simple draught of cool air will at once excite this reflex process.

There is reason also to believe that an exaggerated sensibility of the mucous membrane covering the turbinated bones may not only be a consequence of catarrh, but may also rank among its causes. It is well known that in some persons the inhalation of air which contains dust of powdered ipecacuanha or pollen of certain grasses excites sneezing, asthmatic symptoms, and catarrh. This asthma is certainly a neurosis excited by the local irritation, and it is probable that the catarrh is of the same nature. Again, in cases of infectious catarrh, under which head may be included influenza, measles, and whooping-cough, it is not unlikely that the process is similar. Many ordinary catarrhs are distinctly contagious, as is known in every household; and the contagium, whatever it be, probably causes at first local irritation and reflexly catarrh. Even in health a catarrhal flow will often be induced in susceptible persons by going out of a warm room into a very cold atmosphere on a wintry day.

The facts just quoted are sufficient to suggest from analogy the possibility of some cases of ordinary catarrh being due to "germs" of some kind. Of this nothing is certainly known. The chief arguments in its favour are the contagiousness of some catarrhs, the benefit which sometimes is obtained from the local use of antiseptic sprays or lotions containing quinine, salicylic acid, iodine, and similar substances, and from inhalations of camphor, and, lastly, certain observations on the results of experimentally inhaling the air escaping from sewer-ventilators, which were thought to point in this direction. These arguments have no doubt a certain value, but to ascribe all catarrh to germs, as has recently been suggested, is surely to fly in the face of universal experience as to the connexion between an external chill and the catarrh which shortly follows it.

If it be true that catarrh is a reflex neurosis, it is clear that a treatment which is essentially diaphoretic must miss the mark. It is to neurotic remedies that we must look for alleviation and cure. The indications for treatment are three: we need to soothe the reflex disturbance of the central nervous system, to quiet the local congestion and hyperæsthesia of the nasal mucous membrane, and to arrest the flux, if it have already commenced.

The first indication may be to some extent met by the administration of opium. It is to the sedative influence of this drug on the nervous system, rather than to any diaphoretic action which may result, that Dover's powder owes its reputation in the treatment of catarrh. Laudanum sometimes is distinctly successful in arresting a cold. But the other effects of opium make it not altogether a desirable remedy. Chloral hydrate is free from these objectionable effects; but both opium and chloral are dangerous drugs, and they cannot be pushed with safety. Bromide of potassium is, however, free from these objections; it is by far the safest nervine sedative which we possess. Professor Wood says: "No case of acute poisoning in man with the bromide of potassium has been reported, and I have never seen a single dose of it produce any obvious effect." A case is recorded in which an epileptic idiot took at a single dose no less than two ounces and a half of this salt. No drowsiness was produced, and

[1] Read before the Harveian Society, Feb. 4th, 1886.

Digitized by Google

the only apparent effect was that the fits, which until then had been very frequent, ceased immediately, and had not returned even ten weeks later. The distinctive physiological action of bromide is to depress the reflex activity of the central nervous system—precisely the action required in the treatment of catarrh; and its safety makes it possible to give the drug in such doses as shall produce a distinct physiological effect.

The second indication is to reduce the local congestion and hyperæsthesia of the nasal mucous membrane. Relief may be given in this direction by simply closing the nostrils, or impeding the access of cold air by inserting a plug of cotton-wool. A correspondent of one of the medical journals is enthusiastic over the magical effects of a camomile flower inserted into the nostril! Distinguished authorities in neurology have not disdained to turn their attention to this point. Dr. Ross tells of the relief he has himself experienced, by painting the nasal mucous membrane with simple vaseline, and Dr. Ferrier has suggested the sniffing of a powder by which the locally sedative effects of morphine and bismuth are produced. The former method is simply protective, like the cotton-wool. Ferrier's powder is certainly of some curative value, but its application is extremely unpleasant in the results to clothing, when the moistened powder falls from the nose, a chalky cream. The indication can now be much more satisfactorily and scientifically met by the use of cocaine. This drug both causes local anæsthesia and diminishes local congestion; hence, it affords exactly what we require. I have found that the occasional painting of the mucous membrane, especially over the inferior turbinated bone, with a 4 per cent. solution of hydrochlorate of cocaine by means of a camel's hair brush gives instant relief, and on one occasion, at all events, this measure sufficed completely to arrest a cold without the aid of any other remedy whatever.

The third indication is to arrest the flux if it have already commenced. Here again we are fortunate enough to possess a remedy which exactly fulfils the indication. The first obvious physiological action of belladonna is to produce dryness of the throat, due to suppression of the secretions of the salivary and mucous glands. This is exactly what we require in the treatment of catarrh, and several observers have pointed out the advantage of using this drug, but there does not seem to be a general recognition of the fact. And belladonna is a comparatively safe drug; not that it can be used with the freedom of bromide, but that it gives distinct indications long before the development of poisonous symptoms. The dryness of the throat is almost invariably the first effect, but dimness of near vision, dilatation of pupil, and flushing of the face will be observed before any cerebral excitement will occur; and the poisonous properties of belladonna are much less dangerous than are those of opium, which depresses the respiratory centre.

My plan of treatment for the arrest of catarrh is as follows. I keep a strong solution of bromide (1 in 3) and a bottle of tincture of belladonna (B. P.). When I am conscious of having taken cold, I take two to three drachms of the bromide solution in a small glass of water—that is to say, forty to sixty grains of bromide. I repeat this dose in six hours, and, if necessary, take a third dose at a similar interval. Meanwhile, as soon as a flux commences, I take twenty drops (equivalent to fifteen minims) of the tincture of belladonna in a little water every hour or two until the throat feels somewhat dry. The painting of the nasal mucous membrane with cocaine solution gives great relief, and powerfully contributes to the cure if the catarrh be severe. Since I hit upon this plan I have never failed rapidly to arrest my own catarrhs, nor have I failed in any instance in which I have myself been able to superintend the administration of the remedies.

The following case may serve to illustrate the good which may be effected even when it is not desirable to push the remedies so decidedly. I was telegraphed for by the lady superintendent of the Highgate convalescent branch of the Hospital for Sick Children, of which I have the medical charge, to see a child who was dangerously ill. I found it to be a very rickety girl, aged four, with a highly deformed chest. A stream of catarrhal secretion was flowing from both nostrils, dyspnœa was marked, and the temperature was 101°. On examination of the chest, I found good resonance everywhere, but an abundance of catarrhal râles. I ordered that the chest should be rubbed with turpentine liniment, and that the child should take eight grains of bromide and ten minims of tincture of belladonna every four hours. Forty-six hours later I saw this little girl again, and the note I made was this: "No nasal catarrh; no râles in chest; temperature normal; breathing easy; child seems quite well." Since my previous visit she had been sick once, which had no doubt aided in clearing the bronchial tubes, but the complete arrest of secretion was very remarkable. The great danger of acute bronchitis in rickety children with deformed chests being well known, it is not improbable that in this particular instance a life was really saved by the adoption of a neurotic treatment of catarrh.

NOTES ON DIGESTIVE FERMENTS.

By WILLIAM MURRELL, M.D., F.R.C.P.,

LECTURER ON PHARMACOLOGY AND THERAPEUTICS AT THE WESTMINSTER HOSPITAL, EXAMINER IN THE UNIVERSITY OF EDINBURGH AND TO THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

I.—PEPSIN AS A DIGESTIVE AGENT.

THE test for pepsin adopted in the British Pharmacopœia of 1867 was that two grains in an ounce of distilled water, acidulated with five minims of hydrochloric acid, should dissolve 100 grains of hard-boiled white of egg in thin shavings when digested together for about four hours at a temperature of 98° F. The test instituted by the British Pharmacopœia of 1885 is very different. We are told that two grains in an ounce of distilled water, to which five minims of hydrochloric acid have been added, form a mixture in which at least 100 grains of hard-boiled white of egg passed through wire gauze of thirty-six meshes per linear inch, and made of No. 32 brass or copper wire, will dissolve on their being well mixed, digested, and well stirred together for thirty minutes at a temperature of 130° F. (54·4° C.). It will be seen that in both cases the quantity of pepsin taken is the same, and that the amount of white of egg to be dissolved remains unaltered. There are, however, at least three points in which the tests do not accord. The time allowed by the 1867 test is "about four hours," whilst in 1885 it is limited to thirty minutes. The temperature adopted in 1867 was 98° F., whilst now it has gone up to 130° F. In 1867 we cut our hard-boiled white of egg into thin shavings, but in 1885 we adopt a more elaborate method, and pass it through meshes of a certain size and shape. The necessity for well stirring together the mass is now recognised, whilst formerly it was left to the judgment or taste of the investigator. The difference between the two Pharmacopœias in regard to the tests for pepsin may be summed up shortly. In the new Pharmacopœia the time is decreased to one-eighth, whilst the temperature is raised 32°. This elevation of temperature represents an increase of 16 per cent. in digestive power, so that we lose 87·5 per cent. as regards time, and gain 16 per cent. on the temperature, the net result being that our standard is raised 71·5 per cent., for which too much gratitude cannot be shown.

The standard adopted by most authorities both on the Continent and in America is the quantity of white of egg which one grain will dissolve at the temperature of the body in four hours. In the early part of this year, being on a hospital drug committee, I had occasion to examine in this manner a variety of specimens of pepsin, and as the selection included nearly all the recognised brands the results are not without interest. It may be as well to state in the first place that the specimens were not selected in any way. They were not picked samples obtained from the manufacturers for examination, but were *bonâ fide* specimens bought at an ordinary chemist's shop, care being taken to see that the original wrapper was unbroken, and that they presented no indication of having undergone deterioration by age or exposure to variations in temperature.

The estimation of the comparative value of different preparations of pepsin, although simple in theory, is by no means easy in practice, especially if accuracy is desired. The essential action of pepsin is proteolytic—the conversion of proteids into peptones,—and this is usually taken as the test of the value of the specimen. The first point to decide is whether to use fibrin or egg albumen. Following the example of Dowdeswell and other authorities, and being not unmindful of the requirements of the Pharmacopœia,

Digitized by Google

I employed white of egg. The eggs must be quite fresh, and should be boiled in a uniform manner. The best way is to boil the water first, then put the eggs in altogether and let them boil for ten minutes. If a shorter time be allowed, it will be seen that the white will not separate from the yelk nicely and cleanly. It will be found that on an average fifteen eggs yield 7000 grains of coagulated albumen, or perhaps a little less. Much depends on the state of subdivision of the white of egg. An attempt to obtain uniformity was made by pounding up together the whole mass after the removal of the membrane and yelk, and then rubbing it through a No. 30 sieve. This seemed to answer well, for when suspended in water and examined the particles were found to be uniform both in shape and size. The next question was the strength of the acid, and here again, following Dowdeswell, it was determined to use distilled water acidulated with 1 per cent. hydrochloric acid of sp. gr. 1·150. The specific gravity of the acid was ascertained in the ordinary way by a Westphal's balance, the observation being made at 15° C. The necessity for having beakers of the same size and shape was fully recognised, and the mixture was constantly stirred. The observations were made at a temperature of 38° C. (100·4° F.), that being approximately the temperature of the body. The beakers were maintained at a uniform temperature by placing them in a water-bath with a little jet of gas beneath. It was not thought necessary to use a gas regulator, as the themometer was carefully and constantly watched, and never varied more than a degree, or at the most a degree and a half. The test proposed was the quantity of coagulated white of egg digested by one grain of pepsin in four hours in eight ounces of 1 per cent. hydrochloric acid at a temperature of 38° C. It was thought that the activity of each preparation could be ascertained by filtering the liquid left at the expiration of the time selected, and then, after drying, weighing the residue left on the filter. The whole experiment was a failure, for the simple reason that what was left would not filter: the fluid positively declined to be filtered. It was put on the filtering-paper, and there it remained, hardly a drop passing through, even after standing twenty-four hours. It was not hurried in any way; it was allowed to take its own time about it, but the result was always the same. Different kinds of filtering-paper were tried, and an attempt was made to humour it by folding the papers in various fantastic devices, but it was all to no purpose, and it refused to budge a drop. Finally glass-wool was experimented with, but it would not even go through that, and the whole thing had to be abandoned in disgust.

This plan having failed, another, or rather a modification of this former, was adopted. The white of egg, instead of being passed through a sieve, was cut up by hand into long narrow, thin slips or slices. These pieces were not absolutely uniform either in shape or size, but as fifteen eggs were operated on at a time, and the whole mass was mixed up together, the error arising from this source could not have been very great. The weight of albumen taken for each observation was 1000 grains, as usual. The fluid was eight ounces of 1 per cent. hydrochloric acid of sp. gr. 1·150. The temperature was 38° C.; and the quantity of pepsin employed was one grain of each of the solid preparations and ten grains of those which were liquid. The observations in each case lasted for four hours. At the end of that time the liquid was filtered through muslin and carefully washed for thirty minutes with a small jet of distilled water. The muslin was then spread out on porous paper to absorb the excess of moisture, and allowed to remain exposed to the air at a temperature of 60° F. for twenty-four hours. The albumen was scraped off the muslin and carefully weighed. The figure so obtained was subtracted from the weight originally taken, and in this way the quantity of albumen dissolved by one grain of each preparation was ascertained.

Fifteen solid specimens of pepsin were examined, some of English, others of French, German, or American manufacture. They were all active, but in many the proteolytic power was very small. Only four would have come up to the standard of the new British Pharmacopœia. The name is evidently no guarantee of purity, for a specimen made by a well known firm was represented by the figure 871, whilst another sold under an equally well known name, had to be satisfied with an award of 162, a state of affairs which is unsatisfactory. The same pepsin is often sold under different names, according to the amount of impurity added. I have before me a table showing the exact quantity dissolved by one grain of all the best-known pepsins, but I do not think it would serve any useful purpose to publish it. Better by far that every medical man should make his own observations and form his own opinion. It may be doubted if the Pharmacopœial description of pepsin as "a light yellowish-brown powder" is a happy one, for the most active specimen was a preparation in scales. The pepsin usually supplied to hospitals is, I am sorry to say, of poor quality. In addition to the thirteen solid pepsins, I examined six liquid preparations, wines, essences, &c., and although ten grains were taken instead of one, the results were unsatisfactory, and the only conclusion I could arrive at was that they were not very reliable, although none of them were absolutely inactive. Having used the carica papaya largely in the treatment of various forms of dyspepsia, I determined to try it against the best pepsins, but found that under the conditions already indicated it was decidedly inferior in activity. I examined in all six specimens of papaw obtained from trustworthy sources, but only two would have come up to the Pharmacopœia test. The best papain had about half the activity of the best pepsin. I do not say that in alkaline or neutral media the papains are not more active, but simply that, tested against the best pepsins and by the same methods, they do not give equally good results. Even in a neutral solution the best papain was not equal to the best pepsin in an acid solution. A papaw preparation which in a certain time dissolved 420 grains in an acid solution dissolved 476 grains in a ¼ per cent. carbonate of soda solution and 535 grains in a neutral solution.

No one can doubt that pepsin is a valuable therapeutic agent, and that it is of the greatest possible use in the treatment of many forms of atonic dyspepsia, flatulence, and gastralgia; but to obtain anything like good results it must be given in doses very much larger than those recommended in the British Pharmacopœia. To give only from two to five grains at a time is a palpable absurdity. The reason that such good results are obtained with pepsin in the treatment of infantile diarrhœa is that it is given in proportionately larger doses. To obtain good results in the treatment of dyspepsia two things are essential—first to test your pepsin, and then to give plenty of it.

Weymouth-street, W.

PERFORATING ULCER OF THE INTESTINE.

By JAMES OLIVER, M.B. Ed., M.R.C.P. Lond.,
ASSISTANT-PHYSICIAN TO THE HOSPITAL FOR WOMEN.

PERFORATING ulcer of the intestine is essentially an acute disease, depending as it does upon a localised softening and disintegration of tissue resulting from a plugging of those vessels which run in and nourish the coats of this viscus. Although from the length of time the symptoms may continue, and because of a proneness of the ulcer for some reason or other to recur, the disease may be worthy of the appellation of "chronic," yet, according to the extent and completeness of the occlusion, so the necrotic change begins to show itself in one or all of the coverings, except the serous, almost immediately they become deprived of their sole source of nutrition. The branches of the mesenteric artery pass round the sides of the intestine under the serous coat, and frequently anastomose with each other towards the free border of the gut. They subdivide and ramify in the muscular coat, supplying it with blood, and finally end in a fine capillary network in the mucous membrane and its underlying areolar tissue. If the blood-supply to any tissue of the body be suddenly withdrawn, as happens when a vessel becomes occluded either by an embolus or a thrombus, and collateral circulation be not readily established, death of the part is inevitable. In the brain and spinal cord localised patches of softening may frequently be detected, the result of plugging of the vessels. By the introduction of emboli into the mesenteric arteries we can produce, artificially, perforations more or less complete, corresponding exactly with those ulcers now under consideration. It is therefore evident that the withdrawal of blood from a part can at least produce destruction of tissue apart from any suppurative or inflammatory change. Here the whole destructive process is truly analogous with that of dry gangrene occasionally seen in

Digitized by Google

the extremities of the aged, where the vessels, because of degenerative changes in their coats, become impervious. Collateral circulation, however, is so readily established in the mesenteric vessels, that emboli, unless very complete, can but rarely exert any influence in the production of intestinal ulcer, except as affording a focus for coagulation of blood and the subsequent development of a thrombus. I am inclined to think that deterioration of blood and degenerative changes occurring in the protoplasm of the capillary wall favour the formation of thrombi, and are therefore potent agents in the production of intestinal ulcer. In some cases it is quite possible the cause may be thrombosis, the result of a local phlebitis. Like gastric ulcer, it so far appears to be more common in females than males. Its exciting cause is wholly unknown.

Perforating ulcer is by no means rare. It may occupy any part of the intestinal tract. Most usually it will be found, however, mid-way between the attached and free border of the gut. As a rule, two or three ulcers are to be detected situated close together or at some little distance from each other. They are generally round, but they may be irregular and even somewhat serpiginous in shape. If the perforation be complete, the serous coat usually gives way by rupturing, whilst all the other structures will be found to have necrosed to an equal extent throughout; the muscular coat, however, retracts, and a partial prolapse, so to speak, of the apparently redundant mucous membrane results. One or all of the coats may gradually disappear, the destructive process progressing from within outwards. Recovery may take place at any stage, the loss of tissue being replaced by an exudation and proliferation of cells, which eventually develop new fibrous tissue with a marked proneness to retract, producing a cicatrix of variable shape and size. The affected part of intestine may by a local peritonitis become glued to another part of the bowel or to some other abdominal or pelvic viscus, and the perforation becoming complete, a fistulous communication may in the course of time be established. If the posterior part of the ascending or the descending colon becomes thus completely ulcerated fæcal extravasation will take place into the underlying areolar tissue outside the peritoneal cavity, and with due care the case may be brought to a favourable termination. It is but seldom that a vessel of any importance gives way producing serious hæmorrhage.

The symptoms of ulcer of the intestine are usually very insidious, and the first intimation of the presence of such a grave condition may be the sudden collapse of the patient, the result of rupture of the bowel and escape of the contents into the peritoneal cavity. Pain as a rule is more or less constant, and is a most troublesome symptom. There is general but no localised tenderness of the abdomen on pressure. Usually there is constipation; occasionally diarrhœa. The temperature may reach 103° F.; generally it is but slightly above normal. The pulse is markedly increased in frequency, averaging from 100 to 120. The tongue is usually red and irritable. Sometimes there is retention of urine without apparent cause, which is most probably reflex. There is no pain on voiding urine, unless the bladder has become attached to the gut by inflammatory adhesions.

The treatment is complete rest, with bland, easily digested food. Opiates are very essential; they must, however, be judiciously employed.

Montague-street, Russell-square.

WEST NORFOLK AND LYNN HOSPITAL.—The annual meeting of the governors of this institution was held on the 16th inst., when it was reported that the total number of patients who had received treatment in 1885 was 2437, against 2378 in 1884. Dr. Lowe, who had for some years acted as consulting surgeon to the institution, having left the town, it was unanimously resolved that he be elected a vice-president of the hospital. The financial state of the charity is not satisfactory, the expenditure having during the past year somewhat exceeded the ordinary income.

ASTLEY COOPER PRIZE.—The next triennial prize of £300 will be awarded to the author of the best essay or treatise on the Origin, Anatomy, Results, and Treatment of Tubercular Diseases of Bones and Joints. Essays are to be sent to Guy's Hospital on or before Jan. 1st, 1889, addressed to the physicians and surgeons of that institution.

ON PHIMOSIS IN INFANCY.

BY GEOFFREY HETT M.D.

MY excuse for submitting the following observations on this subject to the consideration of the profession is that my experience leads me to think that phimosis is a morbid condition which is not infrequently overlooked. Its persistence is the cause of much unnecessary suffering among children, and a neurotic habit is often induced which, in some instances, is never shaken off, but continues to exercise a prejudicial effect upon the usefulness and happiness of a considerable number of men during the whole of their lives. It would be advantageous if the following rule were adopted by all those taking charge of midwifery cases: to examine every male child within a few days of birth, and, if the prepuce cannot be retracted by the exertion of a moderate amount of force, to perform circumcision on or about the eighth day of life. The advocacy of such a rule will appear superfluous to many members of the profession, particularly to those who have had special opportunities of observing the diseases of children. That it is, however, not accepted, or, if theoretically accepted, not acted upon by numerous practitioners of midwifery, is sufficiently proved by the frequency with which it is necessary to perform the operation in later life. Complete retraction of the prepuce is necessary in order to prevent the retention under it of the secretion of the numerous sebaceous glands in the mucous membrane of the cervix and glans penis (glandulæ Tysonii). The accumulation of this sebaceous matter, acting as a peripheral irritant through the internal pudic nerves, may, and often does, cause central mischief more or less grave according to the constitution of the child and the amount of local irritation. If the preputial opening be so small as to interfere with the easy passage of urine, the condition will be aggravated by some of this fluid being forced under the prepuce and increasing the congestion of the mucous membrane. The injury resulting from this cause may be productive of nothing more than slight peevishness of temper; but, on the other hand, may give rise to convulsive attacks terminating fatally, and, of course, to any effect intermediate between these extremes. I feel sure that many an unfortunate little boy is credited with bad temper and punished for naughtiness whose irritability is due to neglected phimosis, and consequently entirely beyond his own control. There is also much reason for thinking that the habit of masturbation is frequently led up to by a morbidly excitable condition of the sexual organs due to the same cause. Should no symptoms arise sufficiently severe to call attention to phimosis, and the child grow up to manhood with the defect unremedied, the liability to venereal disease must be largely enhanced by the impossibility of effectual ablution of the penis. The operation of circumcision is, in infancy, almost entirely free from risk if ordinary care be exercised. The only objection to it of which I am aware is the æsthetic one, and this cannot have much force in a clothes-wearing community, especially when the advantages derived from it are fully considered. Circumcision may be performed by seizing the extremity of the prepuce between the finger and thumb of the left hand, drawing it well forwards so that the outline of the glands can be clearly seen through the integument of the penis, and slicing it off diagonally downwards and forwards just in front of the glands with a sharp scalpel. The mucous membrane, which will be found still embracing the glands, should be split along the dorsum *quite up to the cervix*, turned back, and retained in position by a narrow strip of dry lint wrapped firmly three or four times round the penis. No sutures are necessary. The lint becomes saturated with blood, and, when this is dry, remains in position for from two to four days. On its removal the wound will generally be found completely healed, but, if any portion of it be granulating, it only requires the application of a little carbolised oil four or five times a day. I have never seen a case in which the dry lint failed to prevent any excessive hæmorrhage. The eighth day of life is a suitable time for the operation, as the organism of the child has by then become accommodated to its new environment.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, Lib. iv. Prooemium.

CHARING-CROSS HOSPITAL.

SELF-INFLICTED BULLET-WOUND, LAYING BARE AND TRAVERSING THE BRAIN; BULLET REMOVED FROM THE TEMPORAL FOSSA ON THE OPPOSITE SIDE; RECOVERY.

(Under the care of Mr. J. ASTLEY BLOXAM.)

THE unusual result of such serious injury as is recorded in the account of the following case renders it specially interesting. It is true that the injury was in the anterior part of the brain, where perhaps damage is less serious than in any other part, but the injury was so extensive and the danger of consecutive inflammation so great, from the injury by the bullet or from the presence of foreign bodies carried in by it, that the case will prove important in the literature of injuries to the brain. It was evidently not a case in which anything could be gained by the operation of trephining, and the expectant treatment adopted at first was fully justified by the result. Cases are on record where the bullet in similar injuries has simply struck the side of the skull opposite to the point of entry, and then rebounded, merely leaving an indentation. Under such circumstances operation would be useless. Here the bullet appears to have passed completely through from side to side, partly concealing itself in the temporal muscle.

Tom S——, aged eighteen, was brought to the hospital early on Sunday morning, September 24th, with a gunshot wound of the head. The face and neck were both much swollen, and patient complained of pain in the left temporal fossa and at the back of the cranium. There was a wound three-quarters of an inch above and behind the external angular process of the frontal bone on the right side, involving both tables of the skull and exposing the brain, some of which lay in the wound; the edges of the wound were blackened and swollen. No loss of motion or sensation. Patient slept a good deal, but could be easily roused. Pulse 62. The wound was cleaned and dressed antiseptically.

Sept. 25th.—Patient is semi-conscious. Evening temperature 100°; œdema of *left* lower eyelid. Respiration normal.

27th.—Patient was seen by Mr. Boyd, who felt beneath the skin in the *left* temporal fossa what appeared to him to be the bullet or a spicule of bone. Temperature 100·2°.

28th.—There is some subconjunctival congestion of the right eye.

30th.—An abscess was noticed pointing at the attachment of the temporal muscle on the left side, and poultices with belladonna were ordered.

Oct. 3rd.—The wound is granulating and looks healthy; there is very little discharge. He complains of some tenderness over the temporal region of the opposite side. No loss of smell, speech, or memory. Tongue thickly coated. Patient says he feels very well, but is still drowsy.

6th.—Pulse 68, intermittent. Patient complains of pain and tenderness in the neck and between the shoulders. The wound looks healthy; the temporal fossa on the left side is fuller, and the bullet can be felt more distinctly, with fluctuation in its neighbourhood. He passes his urine and motions unconsciously at times.

8th.—The patient says the tenderness is very great over the neck; he lies mostly on the right side. Pulse 64, feeble. He looks ill.

11th.—There is some wandering at night, and he objects to being moved. He passes his urine and motions unconsciously. Temperature last night 100·6°. The bullet, weighing about 2½ drachms, was removed to-day by Mr. Bloxam from its lodgment in the temporal muscle of the left side, a quantity of pus escaping at the same time. He was afterwards delirious.

13th.—The patient looks better to-day, and has slept pretty well.

14th.—All the motions have been passed unconsciously since the operation. He takes food badly; is only semi-conscious. Slight discharge from both wounds, most from the left. Antiseptic dressings as hitherto. Right wound looks healthy; the left is filled by a blood-clot. Pupils respond properly to light. No strabismus. He is difficult to rouse, but when roused he converses rationally.

19th.—The patient passes his motions unconsciously, but knows when he passes his urine. Ophthalmoscopic examination of eyes (atropinised) showed the discs to be clear; no optic neuritis.

21st.—Pain and tenderness along the course of the lymphatics on the left side of the neck. Breath smells very offensive. He is cheerful, but wanders a good deal. Bowels not having been open for three days, an enema was ordered to be given.

The patient gradually improved, becoming every day more conscious, and the wounds healed over without further complication. He was discharged cured on Nov. 11th.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.

A CASE OF OSTEO-MALACIA.

(Under the care of Mr. E. OVERMAN DAY.)

WE are indebted for the following notes to Mr. A. Dixon Jollye.

E. S——, aged eighteen. Family history good, consisting of two sisters and one brother, all delicate-looking, but apparently healthy. The patient was born at full time, but had always been very delicate. She walked at the usual time, dentition being normally performed. Had measles and whooping-cough when twelve years old. Menstruation commenced at fourteen; always regular. The present attack dates from the age of fourteen. She never appeared so strong after the measles and whooping-cough. The first symptom (which was noticed by her mother) was her waddling gait, which was attributed to laziness. Complained of no pain, but said her ankles felt weak. Bandaging was resorted to by her mother, and soon after she had some strong boots made. The ankle bones were then supposed to be enlarged. In a short time (exact time not known) she complained of pain and tenderness in the wrists when playing the piano. The wrists were then likewise supposed to be enlarged. Three months from this date the right knee gave way whilst walking, and she became knock-kneed. The left rapidly followed the same course. She now for the first time consulted a medical man, who ordered her iron supports for the legs, and salt-water baths, from which she derived some temporary benefit. In spite of all treatment, however, she rapidly became worse, and was quite unable to walk. In November, 1883, whilst endeavouring to go across the room, she fell upon her knees.

On examination no signs of external injury were seen. There was marked genu valgum of both legs. The internal condyles were apparently considerably longer and projecting laterally; patella displaced inwards. Complete rest in bed and the application of long Liston splints (without perineal band) soon brought the limbs into a straight position, in which they remained for a considerable time after removal. The patient was very pale and delicate-looking, but appeared to be in her usual state of health.

Lateral curvature now commenced in the cervical region, with a compensatory one in the dorsi-lumbar region. This was supposed to be produced by the continual twisting over to the one side (the bed being situated by the side of the wall, she generally turned away from it.) Her father one day lifted her up by the armpits, when she suddenly experienced severe pain in the left shoulder. When seen soon after the accident there was found a green stick fracture of the corresponding clavicle. Last February (1885) the right femur commenced to arch anteriorly at its centre and outwardly in the lower third.

April, 1885.—The patient is very delicate-looking, thin, and anæmic; has a slight cough, with a few moist râles over both lungs. Heart normal; other viscera apparently healthy. Urine normal; bowels very irregular; frequent attacks of diarrhœa; tongue irritable; teeth good, not notched; no signs of struma. Spinal curvature very marked; concavity towards left in cervical region, and the reverse in the dorso-lumbar region. Right clavicle normal. Left: a large

Digitized by Google

irregular prominence at junction of inner and middle thirds. Sternum normal; ribs markedly beaded at costal cartilages. Abdomen rather retracted, but nothing striking. Humeri apparently normal. Radial and ulnar epiphyses enlarged and tender. Shafts of above bones normal. Right femur curved forwards and outwards at the lower third; left one normal. Marked genu valgum in both legs, particularly the left. Legs cannot be straightened. Slight enlargement of epiphyses of tibiæ and fibulæ. Right foot extended upon the leg and toes flexed, giving the foot a claw-like appearance.

All these distortions gradually increased, and eventually the whole sternum, which previously appeared unaffected, suddenly collapsed from atmospheric pressure. This caused a constant hacking cough and dyspnœa. The treatment all along had been light nourishing foods of all kinds, with quinine and iron and vegetable tonics, but no check upon the progress of the disease was effected. Bromide of potassium and belladonna slightly relieved the cough.

The post-mortem appearances externally were as follows. (The parents were unwilling to have the body opened). Emaciation extreme. Body, four feet and a half in length. Bones of head normal; teeth sound; gums healthy. Humeri, radii, ulnæ (with the exception of the epiphyses of the two latter), together with bones of hand, were perfect. Left clavicle bent at an acute angle; a grooved needle was passed through the bone with the same ease and absence of resistance as through the skin. Such was the case with all the affected bones. Chest: Sternum perfectly collapsed in its extreme length. Ribs project laterally into more or less sharp points. The ribs and pelvic bones are in close apposition. Sacrum bulges posteriorly. Tibiæ dislocated backwards. Left femur curved slightly backwards; measures fourteen inches. Right measures eleven inches. Patellæ displaced inwards; freely movable.

This case was seen by Mr. Bryant, Dr. Pye-Smith, and Mr. Keetley. Mr. Day stated that for some time he thought it might have been a case of late rickets.

WORCESTER GENERAL INFIRMARY.

POISONING BY CHLOROFORM; RECOVERY AFTER SEVENTEEN HOURS' UNCONSCIOUSNESS.

FOR the following notes we are indebted to Mr. Allman Powell, house-surgeon:—

On the afternoon of Feb. 14th Sarah H——, aged forty-four years, was carried to the infirmary, having swallowed, from suicidal motives, the contents of a liniment bottle belonging to a lodger in her house. The bottle, an ordinary eight-ounce one, and the prescription were also brought. The prescription was—Lin. aconiti, ʒii.; lin. belladonnæ, ʒiv.; lin. chloroformi ad ʒii. But it was subsequently learned that the former drugs were omitted in the dispensing, and that what the bottle really contained was about four ounces of lin. chloroformi (B. P.).

Her condition on admission was as follows:—Surface of body cold; lips congested; pupils fixed and dilated; breathing stertorous; conjunctival reflex absent; pulse feeble, but regular; quite insensible.

The stomach was at once emptied and washed out, the contents smelling strongly of chloroform and camphor. She continued in a state of profound chloroform narcosis until next morning. From time to time the breathing was stimulated by an electric current from the nape to the diaphragm. During the night some rigidity of the arms was noticed, and the temperature rose very rapidly, until at 3 A.M, it attained a maximum of 106·8°. After cold sponging it fell at the rate of a degree an hour. At 4 A.M. some movements of the limbs were noticed; and at 8 A.M., after a severe attack of vomiting, she recovered consciousness, which had been absent seventeen hours. A slight attack of gastritis detained her in hospital two days longer, after which she was discharged quite well.

ROYAL INFIRMARY, EDINBURGH.

APHASIA FROM INJURY; SUBSEQUENT HEMIPLEGIA; TREPHINING; DEATH; NECROPSY.

(Under the care of Professor T. R. FRASER.)

FOR the following account we are indebted to Mr. Hugh R. Bramwell, resident physician.

Peter G——, aged forty-four, publican, was admitted on Sept. 28th, 1885, complaining of slight difficulty in speaking and giddiness when walking. Eight weeks before admission he fell through a trap-door into a cellar, and received a severe blow on the left side of the forehead. He lay stunned for ten minutes, and was then carried home. The left frontal region was much bruised, and there was an incised wound over the left eyebrow. He did not speak, although he was conscious, till the following day, when he was able to give a clear account of the accident, but his speech was indistinct. On the second day after the fall he was able to walk out, but returned home unable to speak a word, and he vomited his dinner. The following day he could speak, and complained of headache and giddiness. During the next seven weeks he suffered frequently from pain in the left side of the forehead, and had many attacks of sudden faintness and giddiness, frequently vomited after meals, and his speech was often indistinct. During this time his memory for words became greatly impaired. He had been strong and healthy up to the time of the accident. There was no history of syphilis. Occasional alcoholic excesses were acknowledged. An acquaintance states that he was very peculiar at times.

State on admission.—The patient is a stout, well-developed man of average intelligence. Walks quite well and shows no signs of any impairment of muscular power. He complains of slight pain in the left frontal region, and pressure at the postero-lateral part of this region elicits distinct tenderness. There is an indistinct linear cicatrix just above and behind the left eyebrow. Temperature on admission 98°. He understands everything said to him and answers sensibly. He can evolve intelligible sentences, but his memory for the names of things is very defective. On being shown various articles, such as knives, pens, chairs, &c., he is quite unable to name them, but recognises the names immediately when they are spoken. He can write, but his spelling is entirely at fault. Thus he calls a knife a "nob," and then writes it "sotpa." When asked to write down "I will come," he wrote "If hayh good," then stopped and shook his head and said it was wrong. The same sentence was then written down and he copied it quite correctly. He cannot read out aloud at all correctly, but can evidently understand written language; thus when shown the word "pen" he immediately points to a pen.

Sept. 30th.—Ordered five grains of iodide of potassium three times a day.

Oct. 4th.—Complains of more pain in the head, and giddiness. Speech getting more confused and indistinct, and he seems stupid and dazed. Tongue very tremulous when protruded.

6th.—Kept his bed to-day. Distinct impairment of power in right arm and leg. Can hardly raise right arm at shoulder-joint. Complains of "pins and needles" in right hand. Temperature 97·4°.

8th.—Much more dazed and confused. Memory for names quite absent. Can hardly speak an intelligible sentence. Right arm and leg more powerless. Right plantar reflex much exaggerated. Patellar reflexes both marked, but no difference. Decided impairment of movements of right side of face; wrinkles less marked on right side. No nystagmus. Patient yawns frequently.

9th.—Speech almost entirely lost. When asked his name, mutters unintelligibly. Hemiplegia almost complete. Marked ankle clonus easily obtained in both legs. Mouth drawn to left. Both optic discs very pale, but no other change in them.

10th.—Is now passing urine involuntarily. Right patellar and plantar reflexes much increased. Well marked-bicipital reflex obtainable in right arm.

11th.—Temperature 97°; pulse 64; respiration 20. More drowsy. Sighs and yawns frequently. Fæces are now passed involuntarily. Pupils unequal; right the larger. Marked contracture of flexors of right elbow. Complete aphasia.—11 P.M.: Lies in a semi-comatose condition, and can hardly be roused.

12th.—At 1.30 A.M. the patient was put under chloroform and trephined by Professor Chiene at a point opposite the left inferior frontal convolution. On the inner table being perforated by the trephine there was free hæmorrhage from the middle meningeal artery, which ceased when the disc of bone was removed. On opening the dura mater nothing abnormal could be seen, no signs of inflammation of the membranes, and no accumulation of pus or other fluid. On the chance of there being deep-seated suppuration a very fine cataract-knife was introduced into the brain substance in three directions, but no pus was found. The wound was

Digitized by Google

then closed and dressed. Strict antiseptic precautions were observed throughout. The temperature rose steadily after the operation from 96·2° at 2.30 A.M. to 100·8° at 12 P.M. Patient quite comatose all day.

13th.—Still comatose. Pulse 150; respiration 38; temperature rising steadily. Is fed every two hours with enemata of pancreatised beef-tea. The contracture of right arm and exaggerated reflexes of right leg have quite disappeared since the operation. The wound was opened antiseptically, and a probe introduced, but no collection of blood or pus was found between the membranes. Temperature at 12 P.M., 105°; pulse 167; respiration 54.

14th.—The temperature rose to 107° at 6.15 A.M., and death occurred a quarter of an hour afterwards.

Necropsy.—On opening the cranium the membranes were found to be healthy. The convolutions were much flattened, especially on the left side. The arteries and veins were quite normal. The trephine wound was immediately over the commencement of the Sylvian fissure. Beneath the wound there were several small ecchymoses of recent origin, the surrounding brain tissue being pale and apparently abnormal. On removing the brain, the left hemisphere, but especially the temporo-sphenoidal lobe, was pale and swollen and decidedly larger than the right. The lateral ventricles were dilated, and contained an excess of clear serous fluid. On section immediately through the centre of the trephine wound, the whole of the temporo-sphenoidal lobe was seen to be occupied by a large glioma and surrounding softening; the tumour extended backwards as a uniform infiltration as far as the limit of the posterior horn of the lateral ventricle. It had invaded Broca's convolution and the adjacent parts of the ascending frontal and parietal convolutions. Immediately beneath the superficial ecchymoses in Broca's convolution there was a recent hæmorrhage (apparently the result of incisions made at the time of the operation with a fine knife to explore for pus) about the size of a walnut. A small nodule of tumour, of a similar nature and about the size of a cherry, was situated in the right hemisphere at the middle third of the ascending parietal convolution.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Thoracic Aneurysm treated by the Introduction of Steel Wire into the Sac.—Changes in Bone and Soft Tissues after Amputations.

DR. GEORGE JOHNSON, F.R.S., President, was in the chair at the meeting of this Society held on Tuesday last.

Dr. CAYLEY read a paper on a case of Thoracic Aneurysm treated by the introduction of Steel Wire into the Sac. The patient was a man aged forty-eight, who was admitted into the Middlesex Hospital on June 5th, 1885. He had been suffering from symptoms of a thoracic aneurysm since November, 1884, but it was not till five days before his admission that a pulsating tumour made its appearance at the root of the neck, rising about three inches into the neck behind the right sterno-clavicular articulation. The patient was at first treated according to Tufnell's method and given large doses of iodide of potassium. The tumour continued to increase in size, and it was evident that it must either soon burst externally or extravasate among the tissues of the neck. On June 24th Mr. Hulke introduced into the sac, through a fine cannula, forty feet of steel wire. This caused no constitutional disturbance or local pain, and this portion of the aneurysm became completely consolidated. Towards the middle of August the signs of extension of the intra-thoracic portion of the aneurysm—increasing dyspnœa and severe paroxysmal cough—became more marked, and there was an increase of pulsation behind the sternum and towards the left sterno-clavicular articulation. As it was evident that the aneurysm must soon prove fatal from pressure on the trachea, it was determined to endeavour to consolidate the part of the sac producing this pressure. Accordingly, on Sept. 10th, Mr. Gould, in the absence of Mr. Hulke, introduced a cannula just above the left sterno-clavicular articulation, directing the instrument obliquely towards the middle line, and introduced 34 ft. 9 in. of wire. No constitutional disturbance followed, but no relief was given to the symptoms, and the patient died in a paroxysm of dyspnœa on September 19th. On post-mortem examination a large aneurysm was found springing from the ascending part of the arch and communicating with the vessel by a very large orifice; the whole of the upper portion was completely filled by clot, embedded in which was the wire. The walls of the aneurysmal sac, where it projected into the neck, consisted only of a little condensed connective tissue. The lower portion of the sac, near its origin from the aorta, caused compression and flattening of the trachea just above its bifurcation. The first operation produced the desired result in preventing the imminent rupture of the aneurysm. The size and connexions of the sac rendered the second operation ineffectual.—Dr. GEORGE JOHNSON only knew of one case of thoracic aneurysm that became cured; the man died, aged seventy, thirteen years after the symptoms began. The dangers of introducing wire into an aneurysmal sac were—the causation of intense irritation locally, the liability to the production of embolism, and the tendency to cause ulceration and rupture.—Mr. R. BARWELL agreed that the value of the method of treatment was not yet known. As far as he knew, Dr. Cayley's was the ninth case of aneurysm that had been so treated. He did not think the record was encouraging. The following cases had been placed on record:—1. By Moore, 1864; thoracic aneurysm; twenty-six yards of iron wire introduced. 2. Levis, 1873; subclavian aneurysm; horsehair used. 3. Bryant, 1873; popliteal aneurysm; twenty-six feet of horsehair. 4. Loreta, 1883; abdominal aneurysm; two mètres of fine iron wire; death suddenly ninety-two days later. 5. Rubio of Madrid, 1874; innominate aneurysm; horsehair, two to three mètres. 6. Van der Meulen of Utrecht, 1879; woman, aged thirty-two; aneurysm of brachial artery; catgut. 7 and 8. Baccelli; two cases; 1878. Cases were quoted apparently proving that the manipulation of aneurysms in attempts at operations may prove a powerful cause in the production of consolidation and consequent cure.—Dr. PAUL had operated on a case of aneurysm of the innominate artery occurring in a middle-aged native of India. He had introduced as much as fifteen feet of horsehair through a cannula; there was no bleeding or discomfort. Next day there was slight increase in the size of the aneurysm, but the tumour felt more solid, and pulsation was unabated. The day after the tumour had greatly increased in size; there was much difficulty in breathing; the skin was œdematous over the tumour with a discoloured spot, and the patient was in great distress. Death ensued the third day after the operation. At the necropsy there was considerable coagulation around the horsehair in the aneurysm and signs of inflammation. The case occurred in the General Hospital, Madras.—Mr. BRYANT thought there was more in the method of treatment than appeared on the surface. In cases where neither ligature nor pressure was available, and in which there was not a large opening into the aneurysm, this method might prove of value. He should prefer the use of horsehair, fishing-gut, or catgut, to the employment of iron or other metallic wire. In the case of popliteal aneurysm in which he had adopted the principle of filling the sac with horsehair, there was as much success as possible in the face of ulcerative endocarditis. In cases of thoracic and abdominal aneurysm the method, rightly applied, was likely to be advantageous, and he regarded Loreta's case as favourable so far as it went.—Mr. HOLMES regarded both Mr. Bryant's and Loreta's cases as encouraging; he could not, however, accept Mr. Barwell's view that manipulation was of any value in the causation of consolidation. He believed that Dr. Murray of Newcastle was the originator of the idea of introducing catgut into aneurysmal sacs. The question lay between the introduction of wire and the use of electrolysis; the latter method had proved unsuccessful in his own hands. In Mr. Moore's case the quantity of foreign substance introduced was probably too great, leading to much local disturbance. Mr. Holmes preferred horsehair to iron wire as the material for introduction into aneurysmal sacs.—Mr. HULKE felt strongly that Mr. Moore's method was fraught with danger and risk; the wire used was soft and bent about in all directions. If the opening had been large there was great probability of the main channel of the aorta being entered. The circumscribed hæmatoma that developed in Dr. Cayley's case was possibly due to the employment of a Southey's trocar, in which there were lateral openings through which some blood oozed. He thought there was no risk of scratching the internal surface of the sac. There would be much difficulty

Digitized by Google

in regulating the distance to which horsehair would travel inwards. Wire could be more certainly rendered aseptic than other materials, even catgut. With electrolysis he had had positively disastrous results; ergot was valueless.—Dr. CAYLEY considered that the risk of embolism in sacculated aneurysm was not great; in Mr. Moore's case the emboli probably came from vegetations on the valves. It was generally believed that bruits, being due to fluid eddies, developed by blood passing through narrow orifices, and so the existence of bruits would rather favour the view that the communication between artery and aneurysm was narrow; but he had not verified this suggestion.

Mr. GEORGE POLLOCK read a paper on the Changes which occur in Bone and Soft Tissues after Amputation of a Limb, and from certain other conditions. The changes to which the author drew attention included not only such as are met with in the bone of a stump of an amputated limb and in parts affected with paralysis, but also those observed in parts which have extra work thrown upon them in compensation for the loss of other parts with which they were originally associated and had to act. The differences found in the two lower extremities of an old man who had suffered amputation of one thigh many years before death were described. On the amputated side the femur was found wasted, and the neck joined the shaft at a much more open angle than natural; while on the other side the femur was hypertrophied, and the neck joined the shaft at a right angle. The causes and results of these changes and of the corresponding changes in the two sides of the pelvis were described. The conditions observed in a man whose thigh had been amputated in infancy was related; and reference was made to observations by Mr. Hilton on the changes that follow amputations. The bones of the right extremity from a case of paralysis were also exhibited; they were greatly atrophied and had undergone fracture; while the excessive hypertrophy which occurs in one limb after amputation of the other was illustrated by a well-marked case. The views of various writers as to the causes of the changes in these cases were given, and the author remarked that the alterations in both muscle and bone are often more rapidly effected, and also more extensive, than is generally supposed. He drew attention to the fact that in the cases related two distinct and different processes—the one atrophy and the other hypertrophy—go on side by side, and asked whether this fact may not admit of practical application; whether in appropriate cases, by a careful combination of exercise, position, and rest, together with the use of mechanical appliances, we might not do something to accelerate improvement. A table of specimens was added to the paper.—Professor HUMPHRY showed a specimen of a skeleton in which the right lower limb had been amputated very early in life. The ala of the ilium was remarkably atrophied and incurved; the descending processes were much atrophied; the circle of bone that entered into the formations of the brim of the pelvis was not atrophied, so that neither upper nor lower openings of the pelvis were lessened in size. The femur was very short; the acetabulum diminished in size. At birth the angle of the femur was 140°. The gradual diminution in the size of the angle was possibly due to pressure; but it should be remembered that growth takes place directly in opposition to pressure. The angle varied, but was about 130° in adults; it was in inverse proportion to the development of the pelvis and the stature. It attained its maximum in tall men and was reduced to a minimum in short women. That the angle diminishes in old age was a proposition founded on insufficient evidence. Meckel also doubted whether the angle progressively diminished in size as age advanced. In a case of hydrocephalus, the patient dying at the age of four years, the skeleton was most remarkably attenuated, and the angle of the femur measured 160°; there was no sufficient explanation to account for this occurrence, nor for the fact that after amputations of the thigh the angle was increased in size. Growth of the whole body was associated with the growth at the epiphysial lines; arrest of growth in these lines prevented growth of soft parts of the limbs.—Mr. J. H. MORGAN showed the femora of a man, aged fifty at death, who at the age of twenty-five suffered amputation of one thigh. There was a difference of 3 oz. 5 drs. in the weight of the bones; there was a slight difference in the size of the angles of the femur.—Mr. T. SMITH said the obliquity of the neck of the thigh-bone varied inversely with the length of the stump. He had taught (perhaps erroneously) at St. Bartholomew's Hospital that the angle diminished as age advanced, and this was due to pressure. — Mr. HOWARD MARSH had observed that in some cases of conical stump the fault appeared to be due to a continuance of growth at the upper end of the long bone, as the humerus. Curving in bones meant strength; atrophy generally led to straightness, which was possibly a reversion to the fœtal type, where the long bones have no curves.—Professor HUMPHRY did not consider that a conical stump could develop in a few months as the result of continued growth of bone. He still maintained that it was not a normal law for the femoral angle to diminish with age.

The following is the list of officers and other members of Council nominated for 1886-87:—President: *Mr. G. D. Pollock. Vice-Presidents: *Dr. J. W. Ogle, Dr. Hermann Weber, Mr. Thomas Bryant, and Mr. Matthew Berkeley Hill. Treasurers: Dr. C. B. Radcliffe and Mr. Timothy Holmes. Secretaries: *Dr. W. B. Cheadle and Mr. Howard Marsh. Librarians: Dr. Wilson Fox, F.R.S., and Mr. J. W. Hulke, F.R.S. Other members of Council: Drs. T. Buzzard, W. S. Church, *T. H. Green, *J. W. Legg, *W. Moxon, *H. C. Rose, Messrs. *Marcus Beck, *E. Bellamy, *J. McCarthy, and W. Rivington. Those gentlemen to whose names an asterisk is prefixed were not on the Council, or did not fill the same office last year.

MEDICAL SOCIETY OF LONDON.

Combined Action of Cocaine and Nitrate of Silver in Superficial Affections of the Eye.—Severe Endocarditis.

AN ordinary meeting of this Society was held on Monday last, Dr. Douglas Powell, Vice-President, in the chair.

Mr. BRUDENELL CARTER read a brief paper on the Combined Action of Cocaine and Nitrate of Silver in Superficial Affections of the Eye. He began by recalling how nitrate of silver had fallen out of use, owing to the pain it caused and the difficulty there was in limiting its action to the desired part. Cocaine overcomes the latter difficulty and prevents lacrymation. After making the surface of the eye insensitive by cocaine, the diseased parts can be accurately and definitely attacked by nitrate of silver. In cases of simple chronic congestion, or associated with phylctenula, the results have proved most beneficial. Vascular keratitis was also a possible field for the use of this method. He said improvements in minor points of therapeutics were often of much practical value, and hence he had ventured to bring these facts before the Society. In chronic congestion around an old cicatrix of an operation wound, as well as in the more general superficial congestion left behind in the declining stages of interstitial and other forms of corneal inflammation, the method had also been employed.—Mr. H. E. JULER dilated on the value of cocaine in numerous superficial affections, including tumours of the skin, when a hypodermic injection, carefully administered, was most useful.—Mr. W. H. JESSOP had employed the combination of cocaine and nitrate of silver in cases of corneal ulcer and chronic congestion; cocaine acts on the terminations of the sensory nerves and constricts the blood-vessels.—Mr. B. CARTER had observed denudation of the corneal epithelium as the effect of the use of cocaine.

Dr. A. E. SANSOM read a paper on Severe Cases of Endocarditis; its Causes and Treatment. He objected to the term "malignant," and alleged that in all cases there was loss of tissue—necrosis or ulceration. The first case narrated occurred in a married woman aged thirty, in whom the disease began six weeks after parturition. Embolism of the left radial artery and of the renal artery, albuminuria, hæmaturia, and casts, mitral regurgitation, and high fever were the chief events. The second case was that of a single woman, aged twenty-six, in whom there was mitral stenosis and regurgitation, pneumonia, and (?) phlebitis of right arm and left leg. In both cases there were evidences of septicæmia. What relation existed between the infective foci and the valvular lesions? There was evidence of pre-existing disease of the valves in one of the cases, and this illustrated a general law that obtained in cases of mycosis endocardii; Osler's researches had set this law on a firm basis. When Ort injected fluid containing microbes into a rabbit's vein, having previously caused a traumatic lesion of the valves, a series of phenomena ensued, terminating in death in a few days, with lesions practically similar to those found in the disease in man. It seemed from these experi-

Digitized by Google

ments that varying septic organisms could give rise to the disease, but varying features were met with; the lesions from the use of streptococcus were more severe than those resulting from staphylococcus. It would appear that the cause of osteomyelitis may also give rise to abscesses elsewhere; staphylococcus pyogenes aureus was the infective agent and cause, as artificial cultivations proved. As to treatment, the adoption of preventive hygienic measures was the main line. Parturient women must be protected from septic influences, and especially if there be pre-existent valvular lesions of the heart. A young woman with symptoms pointing to severe endocarditis, under Dr. Sansom's care, improved and recovered after the prolonged administration of thirty-grain doses of sulphocarbolate of soda; in this case there was a very curious mental condition and evidence of extremely low arterial tension. The following propositions were presented for consideration: (1) severe endocarditis is due to the influence of septic micro-organisms; (2) treatment based upon this view gives great prospect of success.—Dr. DOUGLAS POWELL thought the term "severe," even when qualified by non-rheumatic, liable to misconception.—Dr. S. MACKENZIE suggested that the word "essential" would meet all the clinical requirements of the case, the term being used in the same sense as "essential" anæmia; it implied nothing as to pathology. In a severe case he had employed benzoate of soda in twenty- to thirty-grain doses; the patient recovered. But it should be remembered that some severe cases recovered without special treatment.—Dr. S. PHILLIPS considered that neither the term "severe" nor "essential" met the exigencies of the case. Reference was made to cases in which the symptoms were almost "latent." He thought it was open to question whether some of the cases were not due to rheumatic poison.—Dr. GILBART SMITH related some cases illustrating two varieties of the disease.—Dr. SANSOM, in reply, could not agree to the term "essential."

Dr. W. H. WHITE showed a pathological specimen of an Aneurysm of the descending part of the Arch of the Aorta.

The following are the names of Fellows of the Society nominated for office by the Council for the ensuing year:—President: R. Brudenell Carter. Vice-Presidents: J. L. Down, M.D.; S. Cartwright; T. L. Brunton, M.D., F.R.S.; Sir W. MacCormac. Treasurer: A. E. Durham. Librarian: W. H. Allchin, M.B., F.R.S.E.; Honorary Secretaries: J. H. Morgan, M.A.; S. West, M.A., M.D. Secretary for Foreign Correspondence: Felix Semon, M.D. Council: J. N. C. Davies-Colley; S. H. Davson, M.D.; D. W. Finlay, M.D.; J. Fowler, M.A., M.D.; A. Pearce Gould, M.S.; F. De Havilland Hall, M.D.; G. M. Humphry, M.D., F.R.S.; J. Hutchinson, F.R.S.; J. S. Keser, M.D.; S. Mackenzie, M.D.; W. M. Ord, M.D.; Isambard Owen, M.A., M.D.; Bernard Pitts; Walter Pye; J. P. Richards; J. Knowsley Thornton; Frederick Treves; T. T. Whipham, M.A., M.B.; W. H. White, M.D.; C. T. Williams, M.A., M.D.

HARVEIAN SOCIETY.

Neurotic Treatment of Catarrh.—Animal Vaccination.—Cyanosis in Newly-born Children.

A MEETING of this Society was held on Thursday, Feb. 4th, J. Hughlings Jackson, M.D., F.R.S., President, in the chair.

Dr. D. B. LEES read a paper on the Neurotic Treatment of Catarrh, which will be found *in extenso* in our columns.—Dr. CLEVELAND took exception to the view that it was desirable to stop the flux in a common nasal catarrh, and instanced the very common belief that by so doing the catarrh was rendered more liable to attack the lower air-passages. He believed in the value of diaphoretics as proved by the test of experience, and thought that our knowledge of the neurotic origin of colds was not yet sufficiently advanced to warrant such very free use of neurotic remedies.—Dr. STEPHEN MACKENZIE doubted whether there was really any scientific foundation for the popular notions with respect to the infectiousness of catarrh, although many positive statements had been made to that effect. He agreed in the view that catarrh was essentially reflex in its origin, but in the same time diaphoretic treatment was important when applied at the right period. With the onset of a cold the surface was chilled and the interior of the body felt overheated; sweating under such circumstances always gave relief.—Dr. T. NORTON expressed full belief in the contagiousness of colds. He thought that influenza was the most marked instance of it, and bore the same relation to ordinary catarrh as did cholera to ordinary diarrhœa. It was probable that many patients would be unwilling to submit to the active medicinal treatment proposed by Dr. Lees.—Dr. EWART pointed out that the proposed neurotic treatment applied mainly to catarrh of the upper respiratory passages. Local and general catarrhs differed considerably, and the latter were frequently to be seen affecting the whole alimentary tract, especially in children. The treatment in such cases was to encourage the flux and assist its escape as far as possible. Catarrhal inflammation was apt to spread by continuity on mucous surfaces, by means of the sero-mucous secretions.—Mr. J. W. MASON advocated the diaphoretic treatment as being most in accord with the natural process of cure.—Dr. LEES replied.

Mr. SHIRLEY MURPHY read a paper on Animal Vaccination, in which he discussed the advantages and disadvantages attendant upon the use of animal lymph. He argued that the evidence which was afforded by publications within the first ten years after the introduction of vaccination tended to show that humanised lymph now in use in this country was as protective as that of the earlier period. Jenner's experiments of inoculation with small-pox of persons previously vaccinated were performed mostly upon adults, whereas it was noteworthy that those persons who contracted small-pox after vaccination were mostly vaccinated in infancy, and this was true for those of Jenner's time as well as at the present. Animal vaccination was a convenient method of producing large supplies of lymph which in its clinical effects was practically identical with humanised lymph, but its employment had the advantage of avoiding certain dangers associated with the use of humanised lymph, and which deserved to be taken into account, although with care and knowledge they might be reduced to an infinitesimal amount. Much stress was laid upon the superiority of direct vaccination, whether arm to arm or calf to arm, over that which necessitated the employment of stored lymph; and the hope was expressed that vaccination with stored animal lymph would not be allowed to replace arm-to-arm vaccination, and it was pointed out that the best way of utilising the calf would be to modify the virus of small-pox and render it available for the purposes of vaccination.—Mr. WATERHOUSE recounted a series of five cases in which inoculation had produced abnormal results. The lymph in each instance had been taken direct from the calf, was of undoubted purity, and was introduced by scratches in the ordinary way. The first irritation of the inoculation passed off rapidly, but about the end of the first week a pimple appeared, which in the course of three weeks developed into a small tumour bearing an almost exact resemblance to a red currant raised above the surface, intensely irritable and with no areola. He had had many good results from the use of calf lymph, especially in revaccination, where, even in the presence of good scars of primary inoculation, the vesicles were as large and well developed as if no marks at all were to be seen.—Dr. RENNER could only describe the results obtained in Mr. Waterhouse's cases as spurious vaccinia. No harm appeared to have been done. He doubted the exact relation between vaccinia and small-pox. They seemed to belong to the same class of cases, but to be differentiated by their seat. Cow-pox was local and variola general, but both were more virulent in their natural than in their cultivated state. The systemic reaction on the eighth day was due to the irritation of the skin, and was in direct proportion with its severity. The notion that calf lymph was unsafe could only be explained by ignorance or carelessness in its use. Only very few cases of true skin disease had ever been reported as resulting from it. The results obtained from stored lymph of any kind could not be properly compared with those of fresh calf lymph. The risks of inoculation of tubercle had been conclusively proved to be infinitesimal.

At the meeting on Feb. 18th, J. Hughlings Jackson, M.D., F.R.S., President, in the chair,

Dr. SIDNEY PHILLIPS showed recent specimens of the Intestines and Spleen of an Infant the subject of typhoid fever, exhibiting the characteristic lesions in all stages.

Mr. G. EVERITT NORTON read a paper by Mr. Rayner illustrating a peculiar form of Cyanosis affecting a number of newly-born children under his observation. Several children had been affected at the same time, and, although deeply cyanosed, did not exhibit any other signs of ill-

Digitized by Google

health. Careful investigation failed to trace any cause for it until the napkins worn by the infants came to be examined. It was then found that these had all been recently marked with a large stamp in a coloured ink containing chloride of anilin. Further experiments with these napkins upon perfectly healthy children proved that the absorption took place in about twenty-four hours, and the cyanosis continued for about five days, the health of the children not being in the least disturbed.—The PRESIDENT and Dr. SEDGWICK referred to the possible dangers of staining by the internal administration of anilin and to the lowering of temperature which sometimes accompanied it.—Dr. MAGUIRE pointed out that the dye might cause cyanosis either by direct staining or by destruction of the red blood-corpuscles, as in poisoning by chlorate of potash; or, by combining with the hæmoglobin, the anilin might prevent the chemical process of oxidation; either of the latter processes might cause lowering of temperature. One of the cyanosed infants was exhibited to the Society.

Dr. SANSOM read a paper on Modern Remedies in Cardiac Disease, which will shortly be published in full.

ACADEMY OF MEDICINE IN IRELAND.

Ovarian Displacements.

AT a meeting of the Obstetrical Section, on Jan. 8th, the PRESIDENT (Dr. More Madden) read a paper upon Ovarian Displacements, which, he said, apart from those caused by disease, were long completely ignored by gynæcologists, and even yet receive less consideration than they demand. From clinical experience he was convinced that ovarian hernia and prolapse were both much more common than they are generally supposed to be. In every-day gynæcological practice a certain proportion of patients complain, *inter alia*, of dull, sickening, left-side pain, usually referred to the left inguinal region. And in many instances, if further investigation and physical examination were made, this may be found traceable to some ovarian displacement. Ovarian hernia may be inguinal or femoral, though more frequently the former, appearing either as a direct hernia in the inguinal or femoral regions, or in the more usual oblique form, making its way through the canal into the labium. Still more common, however, than either of these herniæ is the prolapsus of the ovary, and more especially that of the left ovary, into Douglas's space, where it may be discovered on examination as a small, oblong, dense, and highly sensitive tumour in the post-cervical recto-vaginal fossa. Ovarian herniæ, although in some instances congenital and occasioned by similar causes to other forms of hernia, are much more usually the result of the violent muscular efforts of the second stage in cases of difficult labour, and most frequently are observed in multipara whose abdominal parietes have been relaxed and viscera compressed by their repeated gestations. But in the most common form of ovarian displacement—viz., that downwards into Douglas's space—the causes are more generally gynæcological than obstetrical, the ovary being either extended from its normal position by the *vis a tergo* of abdominal, uterine, or peri-uterine tumours or enlargements, or else dragged down by the tension of uterine displacements on the ligaments. The symptoms of ovarian displacement are the sudden occurrence in either the inguinal or femoral regions, the labia, or in the recto-vaginal fossa of an ovoid tumour, which in its ordinary condition is usually about the size of a small walnut, increasing, just before the menstrual period, to the size of a Tangerine orange. This gives rise to a dull aching pain, which in the interspace gradually subsides until the functional activity of the displaced gland is again stimulated by the approach of the next catamenial epoch. In some instances, however, the dull, sickening pain and discomfort thus occasioned never subside, but increase to an unbearable extent until relieved by appropriate treatment. From enterocele an ovarian hernia may be distinguished by not being smooth and globular, nor giving rise to gurgling on compression, or resonance on percussion; whilst from epiplocele it may be differentiated by the absence of the peculiar soft doughy feeling, and irregular, ill-defined outline of the latter. From enlarged inguinal glands a displaced ovary may be diagnosed by the smaller size and simultaneous appearance of several glands in the same situation in the former case. From pelvic, psoas, and other abscesses in the groin, ovarian herniæ may be recognised by the history of the case and the physical character of the firm, ovoid, well-defined tumour if ovarian. A prolapsed ovary in Douglas's space may be distinguished from a posterior uterine displacement, or tumour, by recto-vaginal examination and the use of the sound; whilst in the differentiation of this condition from a tumefaction caused by cellulitis, rectocele, a small parovarian cyst, or a pedunculated fibroma, the same methods of examination will serve to determine not only the presence of any uterine malformation, but also the character of the tumour and the existence of any fluctuation. If the uterus be found normal in size and position, and if there be no fluctuation, in the case of any small, well-defined, firm ovoid tumour in this situation, which, on being touched, gives rise to a peculiar dull, sickening pain, we may confidently conclude that we have to deal with a prolapsed ovary. The treatment of ovarian protrusions must obviously be dependent on the situation of the displacement—i.e., whether it be at either of the abdominal rings, or downwards into the labium, or into the recto-vaginal fossa. In the first form, whether the ovarian hernia be above or beneath Poupart's ligament, an effort should primarily be made to reduce it, if possible. In the majority of cases, however, these herniæ are not reducible when seen by the gynæcologist, and even in those which are reducible the pressure of a truss is neither endurable nor effectual. And in the majority of cases we must be content to protect the hernia from any further protrusion or external injury by a well-fitting hollow truss. Before the application of this an attempt should be made to lessen the local hyperæsthesia by topical sedatives, poultices, &c., or, if necessary, by leeching. At the same time this constitutional irritation, always present in all ovarian displacements, should be allayed by free doses of bromide of potassium, which may generally be combined with tonics in these cases. When, however, such measures prove ineffectual to relieve the intolerable, constant, dull, aching pain, aggravated into acute suffering at each monthly recurrence of the menstrual period, when the patient complains of marked gastric irritation, and repugnance to all food is increased to positive sickness of stomach whenever the tumour is touched, and when her health is thus broken down, and her life imperilled by the consequence of this apparently trivial and too often neglected displacement, then we should urge the extirpation of the dislocated and probably diseased gland, in whatever situation it may be extended.—Dr. DOYLE looked upon over-fulness of the intestines as a not uncommon cause of ovarian prolapse. The pressure of the sigmoid flexure upon the left side accounted for the more frequent prolapse on that than upon the right side. Many cases could be cured or relieved by keeping the colon emptied with mercury.—Dr. ATTHILL had very seldom found mechanical treatment of any service in cases of prolapsed ovary.—Dr. W. J. SMYLY showed a fibro-myomatous tumour which he had enucleated from the cervix of a patient in the City of Dublin Hospital. These tumours occurring in this situation are interesting on account of their rarity, and the obstruction which they are liable to cause during delivery. The operation was simple, and the patient made a good recovery. He also exhibited both ovaries and the right Fallopian tube which he had removed from a patient suffering from uterine fibroids, and whose life was seriously endangered by violent hæmorrhages.—Dr. MACAN entirely agreed as to the rarity of cervical tumours and the dangers that might arise from their presence during labour. They might necessitate the destruction of the child, and might subsequently undergo disintegrative changes with accompanying septicæmia. As regards labour, uterine tumours were dangerous in proportion to their nearness to the cervix. In reference to Dr. Smyly's second case, he regarded the removal of the ovaries for bleeding fibroids as one of the greatest improvements in modern gynæcological surgery.—Dr. ATTHILL had formerly relied in cases of bleeding fibroids upon scraping out the uterus and applying nitric acid after the necessary dilatation. Finding, however, that the relief never was permanent, he had abandoned this treatment. As a temporising measure he had experienced better results from the occasional injection of iodised phenol. This might be done once a month where more decisive measures did not seem necessary. Under such treatment he had found the hæmorrhages lessen in amount, and the intervals between them lengthen. Only in a limited number of cases was the pain and hæmorrhage such as to necessitate surgical inter-

Digitized by Google

ference. Enucleation of large tumours was much the most dangerous mode of surgical treatment. When he had formerly tried it he lost patients, and succeeded in removing the tumour only in a few cases. Now he would give the preference to removal of the ovaries, being prepared, in cases where the tumour was large and the ovaries might not be found, to remove the entire uterus. He did not question that palliative measures had formerly been too exclusively relied on.

Reviews and Notices of Books.

Surgical Diseases of the Kidney. By HENRY MORRIS, M.A., M.B., F.R.C.S., Surgeon to and Lecturer on Surgery at Middlesex Hospital, Member of the Conjoint Board of Examiners of the Royal Colleges of Physicians and Surgeons of England. With 40 Engravings and 6 Chromo-lithographs. Cassell and Co., London, Paris, New York, and Melbourne. 1885.

MR. MORRIS'S volume is one of Messrs. Cassell's series of clinical manuals, and it is destined to take a very high rank in this series. The surgery of the kidney has become of late years a very important branch of practice; and the extension of surgery to an organ which has been generally considered to be quite beyond the reach of the knife has necessitated a much more careful study of many of the points in the anatomy and pathology of this organ than was essential so long as it was relegated to the care of physicians only. This is rendered abundantly evident in the work before us. In the opening chapter we have a short account of the regional anatomy of the kidney. This is followed by several chapters on the various misplacements, malformations, and irregularities met with in the kidney; for so soon as surgery approaches an organ, such facts assume the highest importance. Then follow descriptions of injuries of the kidney and their sequelæ and complications. From this the reader is taken to consider the renal affections secondary to diseases of, or operations upon, the lower urinary organs. In the concluding chapters renal calculus, scrofulous kidney, tumours of the kidney, and operations upon the kidney are described.

An enumeration of the ground covered by Mr. Morris clearly shows that a new line has been struck out, and that in this manual we have a distinct addition to surgical literature, which gives information not elsewhere to be met with in a single work. Such a book was distinctly required, and Mr. Morris has very diligently and ably performed the task he took in hand. Everywhere the chapters show abundant evidence that neither time nor pains have been spared to collect material from all accessible sources, and it is a full and trustworthy book of reference both for students and for practitioners in search of guidance. If we were to make any exception to this comment on the work, it would be directed to the chapter on tumours of the kidney, in which we think that sufficient pains have not been taken to distinguish between sarcoma and carcinoma. The term "cancer" is sometimes employed, and if it is used as referring exclusively to carcinomatous growths, the information is misleading as to the relative frequency of this form of malignant tumour, for primary sarcoma is much more frequent than primary carcinoma. This error has probably arisen from including under the latter cases which are described as "cancer," that term being used to signify a malignant tumour only, and not a special anatomical structure. The illustrations in the text and the chromo-lithographs are beautifully executed. The work altogether will considerably add to Mr. Morris's reputation as an author.

A Complete Pronouncing Medical Dictionary, embracing the Terminology of Medicine and the kindred Sciences, with their Signification, Etymology, and Pronunciation. By JOSEPH THOMAS, M.D., LL.D. Pp. 844. Philadelphia: J. B. Lippincott. 1886.

THIS work is a creditable attempt to supply the student with a dictionary of convenient size, to which he may refer when he meets with an unfamiliar word in the course of his reading. The words to which significations are supplied are printed in clear type. The etymology is then given from the Latin and Greek where this is known, and occasionally a French synonym is added. The explanations are generally short and to the purpose. The pronunciations are, as all such efforts must be, very unsatisfactory and curious. "Koo-deh-von," however the vowels may be accentuated and marked to pattern, scarcely represents the sound a Frenchman makes when he employs the expression "coup de vent."

It is natural and reasonable to contrast Mr. Thomas's work with the well-known works of Dunglison, Littré, Lanzilotti-Buonsanti and Pini, and with the lexicon now in course of publication by the New Sydenham Society by Messrs. Power and Sedgwick. We venture to take "Blood," the first word that presents itself to our minds, and compare the treatment it receives in these five works.

In Dunglison we find it derived from the Saxon "blod." The synonyms given are "sanguis cruor," "lapis animalis," "hæma," "blede" (old English), and "sang" (French). A tolerably good account of blood is then given, in which, however, the morphological elements of the blood are only incidentally mentioned, whilst the unsatisfactory chemistry has nearly a quarter of a column devoted to it, and the same space is wasted in giving the estimates of nineteen different authors in regard to its quantity, the list concluding with the absurd estimate of Keill, who put it at 100 lb. A short statement of its variation in disease follows, succeeded by a brief description of words compounded with blood, as blood-casts, blood-disease, blood-letting, blood-pictures, and the like. Blood-corpuscle is remarkable for its absence.

The account of blood in Buonsanti and Pini is very short and poor, but it is near the close of the second volume, which has been unaccountably curtailed, probably from impatient subscribers complaining of its tardy issue, little knowing the labour it requires.

The article "Sang" in Littré's "Dictionnaire de Médecine" occupies nearly five columns closely printed, and not far short of those of this journal in length. One column is devoted to chemistry, a little more than one to a description of the blood, and the remainder to its alterations and comparative physiology. There are numerous cross references; altogether it is a very good description.

The article "Blood" in the Sydenham Society's Lexicon occupies nearly three columns, and with the compounds nearly six. The synonyms in six languages are given. The general characters of the blood as a whole are shortly but clearly described, then those of the red and white corpuscles of the serum and of the crassamentum, and finally there is an account of their development.

In Dr. Thomas's Dictionary the account of blood is meagre. The Latin, Greek, and French synonyms are given, the pronunciation of the French *sang* being given as "son," which is hardly correct. It is explained as being "the red fluid which circulates through the cavities of the heart, the arteries, and the veins." Why are the capillaries omitted? It is stated to be "red, and usually warm in vertebrated animals"; but surely the amphibia, reptiles, and fishes would outnumber birds and mammals. In regard to the chemistry, which is next described, it errs as far in brevity as Dunglison and Littré do in prolixity, or it is merely said that it "contains albumen in three states of modification—viz., albumen properly so called, fibrin, and red particles"—a description

Digitized by Google

which we fear would be marked with a "0" in an examination paper. Serum and clot are then briefly described, and ten lines more are devoted to arterial and venous blood. We think "blood" required a more extended notice than this.

In regard to materia medica and therapeutics, the author has not thought it expedient, perhaps from considerations of space, to give the officinal preparations of any other country than the United States. There are many words absent that we should have expected to find: thus cestode and trematode worms receive no mention; the forms of cells such as prickle, ribbed, adelomorphous, and the like, are omitted; none of the varieties of cataract are given; and the mineral springs of Europe and of America are not alluded to.

Still, though there are a good many shortcomings, the work on the whole is a valuable one. The author must be a man of considerable erudition, and the student will find it a serviceable addition to his library.

The International Journal of the Medical Sciences. Edited by J. MINIS HAYS, A.M., M.D., Philadelphia; and MALCOLM MORRIS, F.R.C.S., London. New Series, Vol. 91. London: Cassell and Co. 1886.

THE first number of this journal does great credit to the editorial staff, and will do much to secure a large circulation for the new periodical. The American Journal has long held a very high place in medical periodical literature, and the change it has now undergone has only strengthened it in all its good points. We can only hope that the editors will be able to publish as good a volume as each quarter comes round; if they do they will confer a great benefit upon the whole profession. It is impossible to refer, however briefly, to every article in the volume before us. It opens with a scholarly essay on Modern Medicine of the English-speaking Race, from the pen of Sir Henry Acland, in which is furnished a justification of the new undertaking. Then follows a discussion on the Mitral Cardiac Murmurs by Dr. Austin Flint, in which the reader will find abundant evidence of careful study and patient, exact, clinical observation. Dr. Flint considers that there are four mitral murmurs—the systolic regurgitant, the systolic non-regurgitant, the presystolic, and the diastolic. Sir James Paget contributes a short article on Imperfect Symmetry, in which he points out the departures from perfect symmetry, even in parts most alike—as the two sides of the same body; and he submits that these need more extended study, and that asymmetrical disease is as important as symmetrical disease, to which he and Dr. William Budd drew attention many years ago. Dr. Noland Mackenzie relates a case of "rose cold" in which a severe paroxysm was excited by the presence of an artificial rose free from odour or powder, from which he infers that psychical influences play an important part in this strange affection. Mitral Stenosis is discussed by Dr. Broadbent at some length, and mainly with a view of attaching diagnostic and prognostic meaning to some of the combinations of modified sounds and murmurs met with in this disease. Dr. Swan Burnett writes to show that in mumps the conjunctiva and optic nerve may be affected. Dr. S. E. Post contributes a paper on Kolpohysterectomy, with a very carefully prepared and full table of cases. Many isolated cases of interest are reported, and Mr. Hutchinson furnishes the first part of a valuable article on a Clinical Classification of Tumours. It is much to be regretted that it was not possible to publish the whole of this suggestive article in one number, for in these days, in which there is so much to read, it is a pity that even the most trifling difficulty should attend the perusal of matter of exceptional interest. The reviews are carefully done, as are also the summaries of the progress of the various departments of medical science. The entire volume is one that can only give great satisfaction to a careful reader.

The Science and Art of Midwifery. By W. T. LUSK, A.M., M.D. London: H. King Lewis.

THIS work, first published three years ago, has now reached a third edition. We reviewed the first edition fully in our columns, and the present edition consequently does not require an elaborate notice. At the same time we must repeat our high opinion of its great excellence, and also point out some of the many additions made in the present edition. The treatment of the vomiting of pregnancy, Bandl's ring, relaxation of the symphyses, the care of the new-born, the use of the incubator, the management and treatment of pelvic presentations, shortness of the cord, spontaneous version, expulsion, and evolution are more fully treated, and much new material has been introduced under each head. The chapter on puerperal fever has been in great part rewritten, and forms the best exposition of the subject to be found in any English text-book. As a full exposition of the subject of which it treats, we know of no work of greater scientific merit, or a safer guide in the practice of midwifery.

An Introduction to the Use of the Laryngoscope. By ARCHIBALD E. GARROD, M.A., M.B. Oxon., M.R.C.P. London: Longmans, Green, and Co. 1886.

THIS is, in the words of the author, "a handy guide to practitioners who may wish to acquaint themselves with the use of the laryngoscope." It is a small book of fifty-four pages, and it is not pretended that it is anything but a manual to teach the use of the laryngoscope. It can be useful only as an introduction to a larger treatise on diseases of the larynx, for a classified synopsis of their appearances in Chapter IX. is all the information afforded with regard to them. For beginners who wish to know something about the history of the laryngoscope, the method of using it, and the chief points in the anatomy and physiology of the larynx, we cannot point to a simpler or clearer epitome.

SEQUEL TO A CASE OF LYMPHADENOMA.

To the Editor of THE LANCET.

SIR,—In the hospital reports of THE LANCET for the latter part of 1883 a remarkable case of Multiple Lymphadenoma which came under my care, and was cured by arsenic, was reported. There were large bunches of enlarged glands in the neck on both sides, in both axillæ, in both bends of the arm, in the groins, in the abdomen and the bronchial glands. The man was perfectly cured by arsenic given in five-minim doses. After his discharge I met him in a state of intoxication, and strongly cautioned him about drink. A few weeks afterwards he came to me, having suffered a slight relapse. The cervical glands had begun to enlarge again. I gave him a prescription for the arsenic, and again cautioned him about drink. A short use of the arsenic sufficed to remove all swelling of the cervical glands. From this time I saw nothing of him until I was called in to attend him for acute congestion of both lungs—a very common affection here in hard drinkers. He died after a few days' illness. The glands showed no signs of disease.

I am, Sir, yours, &c.,

R. H. BAKEWELL, M.D.,
Visiting Physician to the Christchurch Hospital.

Dec. 1885. New Zealand.

UNIVERSITY COLLEGE, LONDON.—The Rev. Charles Beard, Professor Sidney Colvin, Alex. John Ellis, Professor Alfred Goodwin, Professor Christopher Heath, Professor Alex. B. W. Kennedy, Professor E. Ray Lankester, William Blake Odgers, the Right Hon. the Earl of Rosebery, and the Rev. Edward White, have been admitted as life governors of the College. The Fellows admitted are—Messrs. T. W. Allen, Arthur Bersy, A. G. Bourne, L. H. Edmunds, W. A. Gostling, G. B. Mathews, F. W. Oliver, and Charles Platts.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 27, 1886.

THE subject taken by Mr. BLAND SUTTON in his recent lectures at the College of Surgeons was well chosen and ably treated. That pathological processes play a part in the differentiation of species, and that such processes are themselves subject to the laws of evolution which dominate all creation, are ideas which require for their full treatment a wide and extensive knowledge of animal life in its aberrant forms and in its morbid states. Mr. SUTTON'S contributions to morphology and comparative pathology have already proved his capacity for dealing with the more extensive subject which formed the theme of his lectures, and he has succeeded in throwing a new light upon some of the most intricate problems of pathology. In his first lecture he endeavoured to show that "correlation," or the processes of hypertrophy and atrophy, which are often intimately connected, can account for the production of racial and sexual distinctions. We do not believe that any pathologist will take exception to his definition of hypertrophy. It is true that the phrase, like that of "tumour," has come to be used very loosely, but we imagine that the laxity of language must be ascribed rather to the clinician than to the pathologist. Nevertheless, it was well to remind us that "overgrowth" and "hypertrophy" are not synonymous terms—that the excessive growth of a toe-nail or of the incisor tooth of a rodent is not comparable with the hypertrophy of a fibula in consequence of its being called to take the place of a tibia disabled by a united fracture. The demonstration that the ischial callosities of the cynomorphous monkeys are allied in nature and origin to the acquired epidermic hypertrophies known as "corns" was complete, and justified the assertion that a pathological production can be transmitted hereditarily and may assume the importance of a racial peculiarity. Correlation, however, implies the predominance of one part or organ;—in excess side by side with a dwindling even to entire disappearance of an originally associated organ—as illustrated in the hypertrophy of one kidney with concomitant atrophy of its fellow, and in the normal development of the tibia, which outstrips the fibula owing to the greater blood-supply it receives from being called on to perform the more important function. The application of these principles to the differentiation of the sexual organs formed one of the most interesting and original portions of this lecture. Hermaphroditism, which is the prevailing condition in the lowest animals, and which obtains to a certain stage of existence in the most highly organised, gives place to sexual diversity by a process of correlation. If the process be incomplete or arrested at any stage, sexual reproduction is impossible. Another example of the same kind was given in the replacement of gills by the allantois, which takes on the function of respiration. It may indeed be a question how far it is legitimate to apply the pathological term "hypertrophy" to such conditions; but we confess that, having regard to the essential changes that underlie hypertrophy, it is not possible to draw any line of distinction between the normal evolutional changes in the formation of the individual and the so-called morbid changes. We seem here to stand on the border line between the normal and the abnormal, which, after all, are but ill-defined terms in themselves.

From this wide generalisation Mr. SUTTON passed in his second lecture to explain, on the doctrine of the struggle for existence, the much-debated question of inflammation. Here the whole array of facts was presented to explain the *rôle* of the leucocytes, and the reason for their migration from the vessels in inflammation. The manner in which these problems were attacked was ingenious, and some of the statements put forward were remarkable in overturning fixed notions concerning the powers of cell life. The lecturer's view ranged over the whole of the animal kingdom, to prove that cells possess the power of ingesting and digesting foreign matters. The observations of METSCHNIKOFF, which were largely quoted, went even further, for they seemed to indicate that cells could perform the active function of surrounding and attacking, as well as consuming and assimilating, such foreign material and, moreover, that the cells could select as well as attack. What a valuable contribution to the philosophy of the Unconscious one has in these facts, if facts they be! and what a fresh impetus they give to the cell theory, which of late has been too much put into the background! But the part played by the living motile cells of the organism includes, we are told, the removal of useless organs, and the sketch given of the way in which the phagocytes consume, portion by portion the no longer required tail of the tadpole was startling to the mind content to believe that disappearance of such organs was due to loss of function and diminished blood-supply. However, assuming the premisses, the conclusion arrived at was a natural one—viz., that the presence of any irritant in the tissues will excite, according to the nature of the irritant, the greater or less accumulation of cells (leucocytes) to that part to attack the foreign intruder, and, if possible, to destroy it and render it inert. It is a bold generalisation, but it must not for that reason be set aside as too intangible; it should be capable of proof, or, at any rate, the facts upon which it is based ought to be easily confirmed or set aside. Mr. SUTTON has done good service in bringing this aspect of the subject of inflammation before the notice of pathologists who will, we trust, not be slow in testing its accuracy.

The etiology of neoplasms, which formed the subject of Mr. SUTTON'S third lecture, is a problem which has long engaged the attention of pathologists, and it was the latest explanation—that advanced by COHNHEIM of the origin of tumours from "germinal rudiments"—that Mr. SUTTON strongly put forward as the most reasonable. Of course, in the case of some tumours, as sarcomata, it is not possible to demonstrate the existence of such rudiments, but Mr. SUTTON showed that they could be found for enchondromata and osteomata, and suggested the high probability of the carcinomata arising from abnormal down-growths of epithelium. A great feature of this lecture was the attention directed to the teratomata, including congenital cystic tumours, and the suggestive inferences as to the origin of these latter from disused ducts or tubes. We need not dwell upon these questions here—the lecture speaks for itself,—

except to state that it would be difficult to disprove statements which have so firm a foundation in embryological facts. We are grateful to Mr. SUTTON for having impressed upon us the great doctrine that pathological processes are subject to the same laws as physiological; that pathology affords scope for a far wider range of inquiry than has yet been bestowed upon it; and that many of the problems which surround pathogenesis may find a solution in the observation of the lower animals and in the facts of embryology.

THERE are many aspects of suicide; for example, the social, the personal, and the moral. Our present and more special concern as medical men is with what may be designated the psychological. What is the state of mind that favours or incites to suicide? We may at once set aside those cases of self-destruction which are, as it were, symptomatic incidents or the direct issues of disease, such as the suicide of a person who suffers from suicidal mania existing before the catastrophe. We may also omit from consideration the very large class of cases which, if they be related to insanity in any real sense, have wilful suicide for their cause and madness for the outcome; we allude to those many instances in which a man, driven to his wit's end by trouble or remorse or shame, kills himself, but does the act in so bungling a manner that he lives for hours or even days after he has shot himself or cut his throat, or taken an irritant poison, and during the interval between the injury and the death exhibits symptoms of an insanity which is really the effect and not the cause of the act of self-murder. A legal fiction covers these cases, and with them most others, with the figment of "temporary insanity." We very much doubt whether there can be such a malady as that which it is sought to hypothecate for the convenient explanation of these cases. An epileptic may be suddenly seized with an impulse for which his will cannot be held responsible, or a maniac may have paroxysms of mental disease, and in either of these transient states the subject of the malady may kill himself though he is more likely to assail the life of someone else; but in such cases there is evidence of disease of the brain—we do not mean coarse lesion, but such pathological conditions as are commonly indicated by mental derangement,—and this evidence has either been forthcoming on previous occasions or will be forthcoming afterwards, if the patient should recover from the injury by which he has sought to put an end to his life; and the morbid state is, as a matter of fact, chronic or recurrent. In the absence of evidence of the sort to which we are now pointing, it must, we think, be held to be in a scientific sense unjustifiable to assume the existence of insanity in any form. Allowance will, of course, be made for a class of cases—not a very numerous one—in which the act of suicide is either the earlier or a very early symptom of insanity, and in which death occurs too quickly for the development of any other symptom, so that a precise diagnosis is impossible. This class of case is plausibly made an excuse for considering all deaths by self-murder instances of insanity. It is assumed that if the person who committed suicide had not died immediately there would have been evidence of his insanity. We concede this is a plausible, as well as a convenient, hypothesis; but it is manifestly a pure assumption almost involving a paradox, to designate this state of matter as "temporary insanity." If insanity existed, it might very well have been persistent. It is only temporary in the sense in which all things happening in time are temporary. If instead of dying the person had lived, there would have been insanity which may have been permanent. It would be far more reasonable to describe the cause of suicide as sudden or commencing insanity. To call it "temporary insanity" is altogether absurd.

Wholly apart from the theory of insanity, suicide has its psychological aspect, and it is to this we would direct attention. Distress of mind may be so great as to impel a perfectly sane mind to seek an end to its miseries in death. The sooner this truth is perceived the better will it be for all concerned, both the distressed and those around them. The notion that no one would commit suicide unless he were insane is by no means reasonable or well founded. There are states of mental agony in which the mind is in no danger of losing control of itself, and yet it is often in very great peril of being driven into a corner without seeing a way of escape, and of assuming that death is preferable to life. It is vain to try to make ourselves believe, or to persuade the experienced and observant, that anyone and everyone in his senses must needs choose to bear the ills that are rather than fly to others he knows not of. When extremities of mental misery are reached, the sane and sound consciousness is quite capable of forming a rational judgment that nothing in the future can be more terrible than the present horror. There is in all minds a tendency to think better of the unknown than of the known. The sincerely religious man, who has no doubt about the reality of his spiritual impressions and conceptions, looking at the matter from his point of view, naturally and reasonably enough imagines that it is impossible for a man to dare death and the future rather than endure any form of trouble in this life. The non-religious, or merely formal believer, does not, however, in his inner conscience feel the same, whatever may be his glib professions on the subject. It is quite conceivable to him that there are chances in favour of bettering his condition by death, even though it be by putting himself out of existence altogether. We all know how often the irreligious long to die when in pain or weariness. In plain truth, no inconsiderable proportion of mankind, we might even say the majority of mortals, are not so impressed with the future but that they would prefer to incur its risks rather than prolong the endurance of some agonies, mental and physical, here; and though we may think such persons very much in the wrong and self-deceived, we have no right to describe them as *insane*. They are as sane as those who take a different view. Why, then, should we so earnestly strive to find an explanation for self-murder by supposing temporary or any other form of insanity as its excuse? Psychologically, there is nothing whatever to necessitate or call for the idea of mental unsoundness in explanation of suicide.

The point for us, as the friends and counsellors of the sick, to consider is, whether it is not desirable to recognise, with a view to help and influence certain states of mind which are in no sense morbid, but which favour the commission of suicide. The position of the practitioner of medicine in relation to these perilous states would be analogous to that

Digitized by Google

which, in another department of his work, the practitioner holds towards the errors of diet, the bad habits, and the insanitary life and surroundings of his patient, which are likely to play parts in the causation of disease. If we would warn a man whom we saw drinking himself into disease or living over a cesspool that he must make certain changes if he would preserve his health, equally ought we to be in a position to warn the man who is in a bad mental state that he is making trouble for himself in the future, and advise him how to mend his intellectual ways. This surely is well within the province of the practitioner, if it be true—as we all know it is—that mind is brain-function. In a certain and very real sense the physician must be a minister not only to minds diseased but to the "distressed in mind," if he would discharge his whole duty; we will go further and say, if he would discharge his immediate duty as a practitioner of the art of healing adequately and faithfully. What general physiology is to pathology, psychology is, not only to the pathology of mind, but to the pathology of those disorders and diseases which are the results of errors in the management of the mental system. From the dawn of consciousness in the child to the ending or consummation, whichever it be, of the human consciousness in death, the medical adviser ought to be the sympathetic and trusted counsellor. "Who is sufficient for these things?" We reply no one perfectly, but all may help, and if all did help there would be incomparably less of the misery and vice that leads to suicide, with or without insanity, and to a multitude of the most intractable diseases that we have now to deplore.

The psychology of suicide is not a subject to be discussed to any useful purpose in the compass of a single article. Let what has now been said suffice to enforce the need of attention to this momentous matter. Hereafter we will try to set forth the leading facts, challenging the consideration of the profession in relation to suicide from fear, suicide from remorse, and suicide from exhaustion.

As already observed in a previous issue, Mr. HUTCHINSON'S recent Lettsomian Lectures contain many points of much practical importance to all who are engaged in the treatment of venereal diseases. Having noticed his views on dualism, phagedæna, and mercurial treatment, we now pass on to his remarks on bubo. He regards scars in the groin as presumptive evidence of syphilis, and believes that it is very exceptional for the typical chancroid to cause no enlargement of the glands at all. These views will not be generally accepted. It is true, as Mr. HUTCHINSON remarks, that our rules of diagnosis have been far too definitely laid down in these matters. But it would be unwise, in the words of the late Dr. LATHAM, "to rebuke the experience of all past times and dictate to the experience of all future," for the past and present history of syphilis shows the revival of many so-called exploded views. That one or more indolent, painless, indurated inguinal glands may occasionally become inflamed and suppurate is a fact of frequent experience, but that it is the exception rather than the rule is equally the experience of most authorities who have had the advantage of large practical observation. On the other hand, the tendency of the typical chancroid is to be the cause of enlargement of the glands as of acute inflammation terminating in suppurating bubo. In dealing with the important question as to whether a patient who had once had syphilis was liable to a second attack, Mr. HUTCHINSON considers that RICORD'S law (which held that he was not liable) holds good in reference to a large majority of cases. But he also contends that exceptional cases do occur, and considers them not more frequent than in the case of variola and measles. Passing on to the very important practical point of incubation periods, Mr. HUTCHINSON remarks how strange it is that its length should still remain a moot point. It is less strange when it is borne in mind how difficult it is to obtain accurate data concerning it. By many practitioners it is regarded as a dry theoretical point of little or no practical importance, while the information obtained from patients can only in a small proportion of cases be absolutely trustworthy. Of how great importance this "moot point" may be we have a very happy illustration in the case which the lecturer has given, where his patient, a young gentleman, was so unfortunate as to contract both gonorrhœa and syphilis, as the result of being once led astray. The gonorrhœa was soon cured, but a chancre made its appearance. The surgeon who treated it, ignoring the possibility of a long period of incubation, misled the patient's uncle, and virtually accused the patient of untruthfulness, because the chancre did not appear till five weeks after the advent of the gonorrhœa. Fortunately Mr. HUTCHINSON was enabled to do the lad an act of justice and to afford real gratification to his uncle and guardian. There can be little doubt that the average period of incubation is, as Mr. HUTCHINSON contends, much longer than is generally supposed, being as much as five or even six weeks, reckoning it as the interval between contagion and the production of an induration which can be diagnosed. It is a fact of great importance in medico-legal cases, as it may go far to prove or disprove a charge of rape or other criminal assault. It is of even greater importance as regards the interval which should elapse between an exposure to contagion and marriage, since every practitioner of experience knows how reckless many men are on this point, and how impossible it appears for them to control their sexual desires even for a few weeks. Moreover, in every case where a patient consults a practitioner for a supposed venereal ailment, the result of impure connexion, the latter will do well to bear in mind this very important diagnostic point, recollecting that, however slight the case may at first appear, it may, after all, turn out to be a case of syphilis.

The subject of recurrent chancres is of great interest, and Mr. HUTCHINSON has given a very lucid description of them, which is well worth reproducing. "Briefly," he says, "it is quite possible and not a very rare occurrence for induration to develop in the retro-coronal fold of the prepuce, which assumes the most exact resemblance to hard chancres, but which are not consequent on any fresh contagion. They occur to those who have had syphilis, and usually but not invariably on the site of former chancres." He would appear to place little value on the presence or absence of induration as a diagnostic point. He regards its presence as proof that there has been no previous attack of syphilis and no application of caustic, but it must be remembered that some of the worst cases of induration are those

Digitized by Google

in which there has been gross neglect and an absence of all proper treatment. These are the cases which, in Mr. HUTCHINSON'S own words, "in size and duration simulate a new growth," going far to show how important a symptom of true syphilis induration is when well marked. As for the condition to which the lecturer has given the term "gonorrhœa-syphilis," it conveys an additional warning of how carefully every case of supposed gonorrhœa should be watched. That the gonorrhœal discharge of a syphilised female should infect a man with syphilis is possible. But that a urethral chancre is often most difficult to distinguish from gonorrhœa is well known, and such being the case it is much more probable that the chancre should escape observation than that there should be no chancre at all.

Of all points noticed by Mr. HUTCHINSON in these recent lectures, none perhaps was more interesting and important than the question as to whether syphilis can be conveyed in vaccination with clear lymph. He evidently considers that this has been conclusively answered in the affirmative by the experiment to which a surgeon recently submitted himself. It has been objected that the lymph might have contained corpuscles, invisible to the naked eye, but visible through the microscope. But whatever may be the true explanation, it is plainly the duty of all vaccinators to ascertain beyond all reasonable doubt that their vaccinifers are not the subjects of syphilis.

In concluding this imperfect notice of these lectures, it is greatly to be desired that all who have the opportunity will furnish the certain classes of facts which Mr. HUTCHINSON regards as still wanting. These are: "Cases in which twins, one or both, suffer from inherited syphilis; they should be followed up through as long a period as possible. Cases in which women acquire syphilis during pregnancy, with especial attention to the question of the freedom of both parents from any former taint; in these cases it is desired to ascertain the effect upon the previously healthy fœtus of syphilis acquired by the mother at different periods of pregnancy. All exceptions, or apparent exceptions, to COLLES' law (that a sucking child cannot infect the nipple of its own mother). All instances of children born alive with indications of syphilis upon them. All cases of pemphigus infantum or of other syphilitic eruptions making their appearance during the first week of life." These, as Mr. HUTCHINSON observes, can only be obtained from those practitioners who are engaged in family practice, who should be rejoiced to aid in so excellent a work as the clearing up of all doubtful points in the diagnosis of such a disease as syphilis. The writings of ACTON, RICORD, DIDAY, BASSEREAU, HENRY LEE, BERKELEY HILL, BUMSTEAD, TAYLOR, and last, but not least, JONATHAN HUTCHINSON, clearly show that, instead of being ostracised from the study and practice of members of the profession, as formerly, the diagnosis, prognosis, and treatment of syphilitic and other venereal diseases form as learned, honourable, and scientific a specialty as any department of medicine or surgery.

THIS is the season of the year when medical men have to face the commercial aspect of their calling, whether they like it or not. During the greater part of the year they follow their arduous pursuits without much reference to being recompensed. The ring of the night-bell rudely disturbs their sleep; the perverseness of disease disarranges their holidays; the tension of individual cases disorders their digestion, possibly their very nerve centres; yet they go on with the satisfaction of men at their post, doing their duty, abating pain and suffering, and in not a few cases adding sensibly to the duration of life and the prosperity and happiness of families. Sometimes the object of their solicitude is the breadwinner of the family, on whom its very subsistence depends; at other times it may be a mere infant of days; but in either case life is at stake, with all its possibilities and relations; and medicine is daily felt to be no holiday calling, but a militant pursuit, a veritable battle with disease from January to December without long vacations, and which, even on Christmas and Midsummer Days admits of very partial suspension. The calling is so absorbing, the objects are so lofty, that medical men are apt to forget that they have to live. The success of their curative efforts is very apt to produce a similar forgetfulness in their patients. The gratitude of patients is often great on their restoration to health, but it is also often evanescent, and health once restored the sensations of recovery and relief are apt to be soon forgotten. Health is regarded as a sort of right, and the agent and instrument by whom it was recovered is allowed to drop out of mind. We will not try to fix the exact number of grateful patients. Once there were ten healed, and only one was found grateful. To do human nature justice, we are disposed to think there would not be nine defaulters now out of ten. But about Christmas-time, for one reason or another, medical men have to prefer their charges and to make pecuniary claims on those whom they have attended. The duty cannot be shirked. They have, as we have said, to live, and the divine character of their profession in no way exempts them from the demands of those whose callings are more prosaic, and who minister to them and to their children. We do not often allude to the commercial aspects of medicine. Perhaps we should do so more frequently were it only to prevent disappointment in many who seem to think it a profession in which failure is almost impossible and living easy. Our object now is rather to remind patients of the nature of the service which they are asked in the medical man's bill to recompense, and which, to do them justice, a large number discharge with grace and generosity. The more intelligent the conception of the nature of medical service, the more cheerfully and the more promptly will the bill be discharged. The days are gone by when intelligent men think of the medical man as the mere master of so many huge bottles, each good for a given symptom or complaint, and to be dispensed by rule of thumb. But even now all men are not quick to perceive in what true medical service consists. In the hope of helping both them and medical men themselves to a true estimate of the value of medical service, we seek here now to magnify it. It may involve no giving of medicine at all. A mere hint to a wise man about the direction in which his health lies, or from which the subtle risk of a breakdown in his health or that of one of his family may be looked for, may be worth all the money that his doctor's bill comes to for all the years of his life. The best medical service is that which averts disease,

Digitized by Google

or puts the patient in the way of avoiding it for the future. Add to such deep service as this the relief of actual suffering, the limitation of infections, the tiding over of grave crises, the timely and wise selection of appropriate remedies, the performance of surgical operations more or less serious, and medical service becomes precious, and the cheerfulness and generosity with which it is paid for will be limited only by either the intelligence or the means of the patient. It is with such views that medical accounts should be made out, and with such views that they should be discharged. Our opinion is often asked as to the scale and sum of charges proper to be made in certain cases. It is of far more moment to make clear to the public the profound and far-reaching nature of medical service and the arduous character of the medical calling. The medical profession has never been wanting in mercy, in readiness to help those who "cannot recompense" it; but this very quality of mercy has been abused, and the profession and the public will only gain by a stern determination to raise the public estimate of the value of medical service.

No better subject for discussion at a Clinical Society could be chosen than that of Meningitis. The ignorance that still prevails about it, the variety of its clinical course, the difficulties of diagnosis and prognosis, the questions of its etiology and natural history, all combine to render the subject as fascinating to the clinical physician as it is monotonous to the morbid anatomist. Its modes of onset are multiform, and its further course and ultimate issue are as uncertain as any process can possibly be. Mere languor and lassitude, unexplained pyrexia or constipation, vomiting without other symptoms, fits of all kinds, hemiplegia, disturbance of pulse or breathing, and vaso-motor disorders may mark the onset in different cases. At the discussion on Dr. GOODHART'S able and suggestive paper at the last meeting of the Clinical Society many most interesting points were raised. Is otitis interna or media a cause, consequence, or mere concomitant of meningitis? Who can tell? Dr. BRISTOWE stated his belief, in which we concur, that in the majority of cases the aural disease should be regarded as a mere companion of the meningeal inflammation. With regard to tubercular meningitis, this opinion is probably most true; it may be less true of the simple form of meningitis. And this leads up to the first great distinction to be drawn in discussing this disease. It is of the first importance, as Drs. WEST and BRISTOWE insisted, to distinguish between the tubercular and the simple forms of meningitis. Then, bearing this in mind, we ought to consider the difficulties in diagnosis of the two diseases. On the whole, we are disposed to think that tubercular meningitis is far more difficult of diagnosis than the simple variety. A still further distinction is necessary between the diagnosis of tubercular meningitis in the very young and the same disease occurring a little later, before and after the second dentition. Tubercular meningitis may occur at all ages, and cases are on record of its appearance before the first tooth has been "cut." At these very early periods of life the diagnosis is of the most difficult nature, and fatal cases of obscure disease exhibiting most if not all the symptoms of meningitis, have been found post mortem to be destitute of the slightest sign of meningeal affection. To put the case more explicitly:—retraction of the head, convulsions, pyrexia, irregular and rapid pulse, disordered breathing, vaso-motor disturbances, and even squint, have been observed as chief symptoms, when the necropsy has failed to reveal any disease in the cephalic cavity. We should place a mark against optic neuritis, and regard its certain presence or that of choroidal tubercle as the most infallible proof—taken with the other symptoms and clinical course—of the existence of meningitis—of course tubercular if the choroidal sign be present.

On other points raised in the discussion we think there should be more unanimity of opinion than now appears to exist. That simple meningitis may recover seems to us to rest on evidence of the most irrefutable character. That tubercular meningitis may cease to give rise to symptoms must, we opine, be also regarded as beyond doubt. At least it is difficult to explain what happens in several cases unless we accept this doctrine. Cases have occurred in which competent observers have watched the progress of symptoms affording the strongest presumption of the presence of tubercular meningitis, which have progressed favourably for a long time, and then the illness has reappeared with its usual aspect and fatal termination. In one such case that has come under our observation a slowly recovering hemiplegia remained with a child for several months before the appearance of the final fatal illness. A necropsy revealed the signs of an old cerebral softening in the neighbourhood of the opposite internal capsule, together with a mixture of tough and soft inflammatory tubercular products, the respective results of the old and recent morbid processes—a geological kind of evidence that seems to be of a conclusive nature.

A further point is the mode of origin of some cases of simple meningitis. Dr. SYDNEY PHILLIPS spoke of a case of purulent cerebro-spinal meningitis supervening on measles, in which a necropsy proved the accuracy of the diagnosis, and failed to detect any otitis. Dr. WEST stated as within his own experience that other eruptive fevers than measles may be the starting-point of meningitis of a simple kind. One of the most interesting cases that Dr. GOODHART related seemed to show that septic poisoning may also be a cause of simple meningitis, and it is to be regretted that a necropsy was not obtained in his case, which otherwise had every appearance of supporting his opinion; on this etiological point, also, Dr. WEST seemed to entertain no doubt. There was one statement that Dr. WEST ventured to make, on which, if we understood him aright, we should like to join issue. It was to the effect that when tubercular meningitis was in action the temperature never rose above 101° or 102°. As to this we have not the slightest doubt, founded on clinical with subsequent post-mortem evidence, that tubercular meningitis may be accompanied by as high a temperature as any other disease, cerebral, thoracic, or abdominal.

MR. VICTOR HORSLEY will read a paper on Brain Surgery in the Stone Age at a meeting of the Medical Society of University College, to be held on Wednesday, March 3rd, at 8 P.M. The meeting will be held in the Botanical Theatre of the College. Any member of the profession will be admitted on showing his visiting card.

"Ne quid nimis."

MEDICAL MEN AND INFECTIOUS DISEASES.

IT would be very pleasant to believe with Dr. Mantle that some immunity from infectious disease is conferred upon medical men by the very fact of their being constantly exposed to the different infections, and that Dr. Ogle's statistics confirm this view. We are sorry to say that we cannot take this view of Dr. Ogle's statistics, or of the facts known too well to medical men before they were published. Dr. Ogle shows, we may remind our readers, that the death-rate of medical men aged over twenty years from scarlet fever is nearly four times the average rate of other men of the same age, from typhus more than twice, and from diphtheria nearly four times. But the liability of medical men to infection is no new discovery. If anyone doubts this, let him look into the facts concerning typhus and relapsing fever, two intensely infectious diseases, contained in Murchison's book on Fevers, and he will be soon disabused. We can only quote one or two o these facts. Dr. Tweedie, writing in 1833 of typhus, said: "Every physician, with one exception (the late Dr. Bateman), who has been connected with the London Fever Hospital has been attacked with fever during his attendance, and three out of eight physicians have died. The resident medical officers, matrons, porters, and nurses, have, one and all, invariably been the subjects of fever." In 1837 Dr. Cowan thus wrote concerning the typhus then prevailing in Glasgow: "All the gentlemen who have acted as clerks in the Fever Hospital for many years past have been attacked with fever, unless they had it previously to their election." Dr. Murchison had two attacks of typhus at an interval of ten years. We must not encourage the idea that we have any charm against infections; but we must do all we can to preserve the purity of the atmosphere of sick rooms by cleanliness, ventilation, and disinfection.

DIPHTHERIA AT AYLESBURY.

THE vale of Aylesbury, in Buckinghamshire, is a rich grazing district, producing large quantities of milk for human consumption. As it is now an established fact that zymotic disease may be spread by milk which has become contaminated with the poison, it is a matter of great moment when a town, situated as Aylesbury is in a grazing vale, becomes the centre of an outbreak of diphtheria. There is to be a Government inquiry into the cause of this outbreak, the result of which will be of more than usual interest. The sanitary authorities of Aylesbury have given great consideration to the drainage of the town, and with a view of perfecting their system have adopted a modern process of dealing with their sewage at the outfall. It must therefore be disappointing and somewhat disheartening that the town should now be visited by such an outbreak of diphtheria as to necessitate a Government inquiry into the cause. The registration district of Aylesbury has the highest death-rate of any registration district of the county of Buckinghamshire. It has not, however, in the past had a high death-rate from diphtheria; in fact, the death-rate from this disease would compare favourably with that of other registration districts in the same county. It becomes, then, a subject of great interest as to what can be the cause of this development of diphtheria in a locality which has undergone great sanitary improvements. We have frequently pointed out that diphtheria appears to arise independently of sewerage defects, though it is always much aggravated by emanations from sewage. The town of Aylesbury is situated on an eminence above the rich valley which stretches for miles below it, and the soil of which consists of rich black mould, long noted for its fertility. There is more or less of an impervious subsoil which favours the retention of moisture and vegetable decomposition, both of which are conducive to the development of diphtheria.

THE MEDICAL OFFICER OF HEALTH FOR BRISTOL.

MR. DAVID DAVIES, the well-known medical officer of health for Bristol, has been "interviewed," and if impending retirement from the arduous duties of a prominent and honoured career, in which the interests of others have always taken the first place, can justify the process, we cannot complain that he should have been subjected to it. One of the first officers of health appointed in England, Mr. Davies commenced his duties by facing epidemics of typhus and of cholera, the mortality from which was such that the task could only be undertaken with an exceptional amount of personal risk; and though at first the appointment was temporary and provisional, yet it soon became evident that services such as had been rendered to Bristol during the period for which he had been in office could not be dispensed with under the circumstances in which the city found itself. Mr. Davies' student career had been a distinguished one; he had received from the hands of Prince Albert the Cheselden Medal; and he brought to bear upon the official duties which were cast upon him, at the age of twenty-eight, all the energy which he had displayed during his early studies. To tell the record of his services would occupy a volume, for all the great improvements in the sanitary and social circumstances of Bristol which have been going on since 1849 are more or less identified with his name; and when he looks back at the conditions under which the inhabitants of that city were living, as regards such important matters as dwelling-accommodation, water-supply, sewerage and drainage, and prevalence of uncontrolled infection, at the commencement of his career, and compares them with what they now are, he may well, for the moment, ignore the further improvements which he would wish to advocate and press forward, and find satisfaction in the fact that he has more than performed his duty to himself and to his constituency. We are glad to learn that Mr. Davies' retirement takes place at a time when he may expect to spend many years in the enjoyment of well-earned rest and recreation, and we are certain that he will take with him the best wishes of the inhabitants of Bristol and of the many members of the profession who know him either personally or by repute.

THE RECENT CASES OF ACCIDENTAL POISONING.

LAST week we commented on the danger which recent events have too abundantly proved to arise from the want of a distinguishing mark on poisons or mixtures containing poison. The case in which a lad died from the effects of carbolic acid, administered to him in mistake for medicine, was then mentioned. The nurse's error in this case was very deplorable, and it was due without doubt to her using an ordinary bottle for containing the disinfectant. In the face of this fact it is somewhat remarkable that carbolic acid is not one of those substances to which the law requires that the sign of caution should be affixed. Chemists almost invariably mark it as a poison, as also do chemical manufacturers, but such care is optional. The crude stuff is sold by oilmen to any buyer without precaution, and but for its odour might pass for beer, especially when kept in a jug or pint bottle. At a late meeting of the Pharmaceutical Society it was proposed to advise the Privy Council that certain drugs—amongst them carbolic acid—should be added to the list of legally recognised poisons. It appeared, however, that this

Digitized by Google

substance had been purposely excluded from the former list because of its common use in outlying rural districts. Convenience, possibly, may still maintain this exemption; but if so, we may at least hope that some sign of danger may be affixed to a commodity which has not in a few cases been a means of suicide or accidental death. A more serious misfortune of closely similar causation was the poisoning of two persons a fortnight ago with strychnine, near the Old Kent-road. Here also the appropriate label was wanting. Not only so, but the strychnia solution had been placed in a bottle supposed to contain a harmless flavouring agent. It is worthy of note that the medical man who has been the unhappy cause of this double calamity has behaved with commendable frankness in the matter, by taking the whole responsibility upon himself and exonerating from all blame the practitioner associated with him. No doubt his explanation, that the strychnine had been placed for temporary convenience in an empty bottle labeled otherwise and forgotten, is the true one. The verdict of the coroner's jury, implying a censure of extreme carelessness, is not unduly severe in the circumstances. The alleged intention of taking legal action against the defaulting practitioner, however natural to one of the bereaved husbands, is, to our mind, a useless and painful addition to a sufficiently painful case. These various accidents occurring so simply cannot fail to remind all concerned that care as much as skill is essential to treatment. The latter of them also recalls a trusty method in pharmacy which allows the storage of poisons in small quantities only, and in a cabinet devoted to themselves.

THE JURYMEN WOULD HAVE THEIR WAY.

ON Feb. 15th Mr. William Carter, coroner for the Lambeth division of Surrey, held an inquest at the Crown Tavern, Lambeth-walk, Albert Embankment, touching the death of a newly-born male child, who was found dead under an arch in William-street, Lambeth. According to the evidence of the police, the police surgeon asserted that the death had occurred quite recently. There was no evidence as to identity. Under these circumstances the coroner advised the jury to return a verdict of "Found dead," and not to go further into the investigation as to the cause of death. Upon this, a juryman, who appears to have held strong convictions as to the frequency and heinousness of child murder and, what is more, to have had the courage to act upon them, plainly intimated to the coroner that he would not subscribe the inquiry form unless the doctor was called to assist them in arriving at some sort of decision as to how the death had been brought about. The coroner, put upon his mettle, at once threatened the recalcitrant juryman with imprisonment for contempt of court; the threat, however, was not carried out. Had it been, one of Her Majesty's prisons would undoubtedly have had its resources somewhat taxed, for the foreman of the jury and several other of his coadjutors were not slow to inform the coroner of their determination to exercise their prerogative of refusing to find a verdict upon what might seem to them insufficient testimony. Ultimately the inquiry was adjourned in order that a post-mortem examination might be held. We yield to no one in insisting upon the necessity of the majesty of the law being upheld. When jurymen are legally in the wrong they deserve whatever punishment their offence entails. In this case, however, we maintain that the real right was on their side. The very purpose of an inquest is to determine "how, when, and by what means" the deceased came by his or her death. No doubt the coroner was correct in saying that the superior courts had decided "that unless independent legal proof of identity and of a child having had a separate existence was forthcoming, no criminal charge could be sustained." Proof of live birth, however, is presumptive evidence of a separate existence, and, if only for negative reasons, it is obviously desirable that the former fact should be settled definitely. Furthermore, we cannot imagine that the coroner was so purblind as to believe that proof of live birth might not form an important and necessary link in the chain of circumstantial evidence which it was the duty of someone to forge. If, as has been reported, the chief argument against the demand for a post-mortem examination was that the magistrates objected to "unnecessary expense" being incurred, we can only hope that other jurymen will stand upon their rights, as Mr. Jordan did, and decline to "act as dummies" when the law enjoins upon them the specific performance of a highly responsible duty. Where there is any reasonable doubt as to the cause of death, it is of paramount importance that a medical man should be consulted and examined on oath. The *ipse dixit* of a third person is not worth the paper on which it is recorded.

OVER-PRESSURE AT WORKHOUSES.

THE death which occurred last week at the St. George's Workhouse, Borough, demonstrates clearly one of the weak points of our Poor-law administration—viz., the very inadequate provision made for the medical attendance on the sick poor. Not only are the medical officers at our workhouses and sick asylums tasked to their utmost with the care of an overwhelming multitude of sick persons, but they have also to decide, in the case of every admission to the workhouse, as to the actual state of the applicant, and whether the case is to be retained in the workhouse or sent on to the infirmary. Among the cases daily seeking relief there are always a number that stand on the borderland of acute and chronic disease—patients suffering, say, from long-standing disease of the nervous system, heart disease, chronic bronchitis, &c., aggravated by want and exposure, but who only require rest, warmth, and food, to be able to struggle on again; and the more acute cases that demand prompt medical assistance and skilful nursing. Now, to decide at once upon the exact requirements of a case is, even in ordinary times, often a matter of some difficulty, but still more so is it in a season like the present, when the tide of sickness and distress is setting full in the direction of the workhouse and infirmary; whilst, no doubt, a desire exists, now that the wards of the infirmaries are overflowing, to deal with as many as possible of the less urgent cases at the workhouse, instead of forwarding them to the already overcrowded sick asylums. Another difficulty is that the relieving officer, when the pressure is great, may happen to send a sick person direct into the workhouse without bringing the case first under the notice of the medical officer, when it may escape his observation for a day or so, unless specially reported to him. In the present instance there seems to be some doubt whether the patient was seen by the doctor on admission, or whether he was passed into the house without the doctor's cognizance; but there can be no question that the case was one which ought to have been sent at once to the sick infirmary. The blame, however, does not rest, we think, with the officials, but with the system. At the time when the new regulations for the medical attendance of the sick poor at the infirmaries and workhouses were introduced, we pointed out how inadequate, as regards numbers, was the staff allotted to perform the very onerous and responsible duties required, and we then predicted that mishaps would be likely to occur. That they have not done so to a greater extent has hitherto been due to the self-devotion and energy with which the medical staff of these institutions have performed their duties, and to the fact that till recently the pressure, though great, has not been overwhelming. Now

Digitized by Google

that, with the severe and prolonged cold and the prevailing distress, sickness and suffering have risen to almost unmanageable heights, we must regard the present lamentable incident, not as a subject for the censure of individuals, but as showing the necessity for adequately enlarging the staff at these institutions. This could be most readily done by the appointment of clinical assistants, selected from the senior students of the metropolitan hospitals; it would be useful work for them, a boon to the poor, and a sensible relief to our overworked Poor-law medical officers.

BLINDNESS IN RUSSIA.

AT the first Congress of Russian Doctors, which was held immediately after Christmas (our Jan. 6th), many important papers were read, followed by discussions of considerable interest, some of the most eminent members of the profession from the different provinces and universities of the empire taking part in them. A very striking contribution to the study of social and sanitary questions was afforded by a paper by Dr. A. T. Skrebitski on the "Distribution and Statistics of Blindness in Russia." The data employed were chiefly those collected by the military authorities who have to examine young men as they become liable to service in the army. Taking the total for the five years 1879 to 1883, the number examined was 1,388,761, of whom 13,686, or almost 1 per cent., were blind of one or both eyes. In certain districts the proportion was much higher than the average, and some of the largest, or rather most populous, provinces seem to have presented the greater proportion of blind; thus in that of Kieff, which sent up almost the largest number of recruits—namely, 43,118,—no less than 660, or 1 in every 65, were found to be blind of one or both eyes. The smallest proportion of blind was found in Archangel, where it was 1 in 390; but even this is far above the proportion in other European countries. To make the comparison with the statistics of other countries it is necessary to subtract the number of those blind in one eye, which in Russia is found to be only a fifth of the total blind; thus, we may consider that four-fifths of the 13,686 recruits returned as blind were blind in both eyes, so that the ratio of totally blind is about 1 to 125. The ratio in England and Ireland is 1 to 1015, and that in several other European countries is still lower, being 1 to 1406 in Saxony, and 1 to 1429 in Denmark. Dr. Skrebitski's paper has attracted a considerable amount of attention from the lay press, the *Novosti* remarking, "We have surpassed Europe not only in mental but in physical blindness." To any foreigner, however, who reads the Russian medical journals, the valuable original communications with which they literally teem would appear to indicate the reverse of "blindness," in the Russian scientific world at all events.

VESTRY VITAL STATISTICS.

THERE are in this country two systems of official death-rates, that of the central government and that of the local government, for which the Registrar-General and medical officers of health respectively are responsible. There are both advantages and disadvantages in this state of things. The statistics of the Registrar-General have the advantage of impartiality and uniformity, and, as a rule, should be used for comparisons. The medical officer of health, on the other hand, has the opportunities of correcting errors in registration, and such as arise from immigrants dying of infectious diseases immediately after arrival in the district. Hence, an energetic and accomplished medical officer provides statistics which correspond more closely with the real facts than do those that are issued from Somerset House. Although, however, there are many medical officers to whom the public is more indebted than it is commonly willing to admit, and the number of such is fast increasing, there are, here and there, to be found men who entered the public health service as it were by accident, and who, owing to lack of energy and interest or to arithmetical weakness, do not improve the statistics that they take in hand, and who too readily yield to the temptation to make the health of their district appear better than it is, by sedulously rejecting all deaths of non-parishoners in institutions, without taking any account of the deaths of parishioners in hospitals &c. outside the area. The Registrar-General furnishes four times a year corrected returns for London, in which all the deaths in public institutions are assigned to the sanitary areas to which they properly belong. It would be a good thing if London medical officers could be instructed by the central authority to give these official figures in their reports, and, where in any case they thought fit to vary the figures, to give such figures separately, together with the reasons for such variations. If this were the rule, it would be impossible for such a misleading report to be issued as that for Mile-end Old Town, 1884-85. The figures given in this report are not only most meagre, but are hopelessly at variance with those of the Registrar-General. Thus, the medical officer of health gives the deaths from the "seven principal infectious diseases" as follows: small-pox 20, measles 9, scarlet fever 56, diphtheria 12, whooping-cough 40, enteric fever 0, cholera 3—total 140. From this he deduces a zymotic death-rate of 1·2 per 1000, as against 3·2 for London. An examination of the Registrar-General's returns for the same period shows quite different figures—viz.: small-pox 27, measles 22, scarlet fever 88, diphtheria 12, whooping-cough 40, enteric fever 24, diarrhœa 117—total 350, which gives a zymotic rate of 3·2, or the same as that for London. But if correction be made for institution deaths, no fewer than 51 zymotic deaths have to be added, which bring the rate up to 3·6, or exactly three times the low rate given in the report of the medical officer to the vestry.

ACCURACY IN DISPENSING MEDICINES.

IT is not very satisfactory to learn that errors in quantity are not uncommon in dispensing medical prescriptions. Such, nevertheless, is the conclusion arrived at in a report on this subject which we have recently examined. This report, it is true, does not treat of an extensive field of research, but its data have been carefully and impartially studied within their limited area. Most of the prescriptions with which this paper deals were of a comparatively harmless nature, while in the case of those containing poisons the error in dispensing was more often on the side of safety than otherwise and was never a dangerous one. Occasionally, however, the amount of the active ingredient was, from a medical point of view, somewhat seriously in excess of the quantity prescribed. So far as the evidence goes, the work of chemists proper, though subjected to fuller investigation than that of other practising pharmacists represented by co-operative stores and drug companies, has clearly the advantage over the latter. Open surgeries have not received such close attention, but in one of these there occurred a very gross error of deficiency with respect to a drug in common use and not ordinarily poisonous. Such inexactitude, when it erred by falling short of the due total, may not have been quite unintentional. We have known cautious dispensers who, in dealing with strong poisons, acted on the principle of the Roman lictors, and perhaps wisely abated a trifle of the full amount. The deficits above stated were, however, in some cases greater than caution required. No fault could be found in the drugs analysed. The quantities alone were at fault. Yet it is improbable that among the chemists or store-salesmen this was due to any grave defect in weights or measures which had escaped the customary inspection. Nor do we see

Digitized by Google

how monetary considerations, the drugs being cheap, could account for the variations in dose. The errors in quantity were probably due to some extent to the fact that the eye, unaided by a fixed scale, had been too confidently relied upon. We do not believe that chemists or others are, as a rule, given to measure thus roughly even simple ingredients, far less poisons; but it is manifest that rule must be carefully observed in matters like these, where even slight inaccuracies, though perhaps not very hurtful, are in all ways unadvisable. The want of poison labels and appropriate poison bottles is mentioned in connexion with these quantitative faults. For this offence the Poisons Act itself is, by its laxity, largely accountable, and the remedy therefore can only come by fresh legislation. For the inaccuracy law might perhaps do something; but there is a danger that, if too rigorously applied, it might only forge a useless and irritating fetter for a trade not usually careless of its responsibilities.

SLIPPERY ROADS.

"A LARGE amount of equine suffering is annually saved by the sprinkling of sand and gravel in the streets of London. The Commission of Sewers expend about £10,000 a year for this purpose." This paragraph, which appeared in a contemporary last week, is, we fear, likely to create the false impression that all our local authorities are doing their best to minimise "equine suffering." We are sorry to have to bear witness that this is not the case throughout the metropolis. From the allusion to the Commission of Sewers it is probable that the words "the City" should have been substituted for "London." The city authorities deserve credit for the efforts they make to save horses from suffering. Would that we could say as much for the West-end. One of our main thoroughfares the other evening presented a spectacle calculated to cause much distress to anyone who regards a horse as something more than a mere living locomotive. A slight frost had made the surface of the wood-paving slippery as ice, but nothing had been done to give the horses a foothold. True that now and then in the centre of the road might be seen a tantalising mound of sand obviously intended for this purpose, but most certainly not so employed. The life of a London cab-horse is by no means an enviable one. Surely the animal might be spared utterly unnecessary suffering. Such a remark from a cabman as "Would you mind getting out here, Sir? My mare is a capital good one, but she can't face this," does not seem to warrant the self-congratulatory nature of the paragraph we have quoted.

MEXICAN MEDICAL SCHOOLS.

THE not very famous medical school of Puebla in Mexico has ceased to exist, because its professors found that without government assistance, which was denied them, they could not continue to carry on the medical education of their students "with dignity," many essentials for such education requiring funds to an extent which was not at their disposal. So far so good; all right-minded persons will agree that the Puebla professors were right in their determination not to carry on a school when they could not do so in a manner worthy of the noble calling of medicine. It seems, however, according to the editor of a Mexican contemporary, *La Voz de Hippocrates*, that there still exist a number of so-called medical schools in the republic, as those of Celaya, Toluca, Tlaxcala, Orizaba, Jalapa, and Vera Cruz, where the whole staff is represented by a single individual, who unites in himself the appointments of director, examiner, chief of clinic and tutor, and where diplomas are dispensed with so unsparing a hand that quacks with the title of Doctor are disseminated over the country, infesting "even the capital, where they practise a profession of which they are absolutely ignorant." These medical schools, as represented by their respective functionaries, have probably but little sense of dignity, except possibly that which may attach to the possession of the almighty dollar, so that it is hopeless to look forward to their voluntarily following the example of the staff at Puebla. Surely, however, the government of the republic might see its way to giving them a broad hint, or something stronger if necessary, about the propriety of their systems of medical *education* (?)

LECTURES TO HOSPITAL NURSES.

ALTHOUGH we hold, and have expressed the opinion, that it is undesirable for those whose profession it is to nurse the sick and needy to acquire a mere smattering of medical and surgical knowledge for the purpose of applying it without proper direction, we are quite ready to admit that seeking good sound instruction at the hands of hospital physicians and surgeons is worthy of encouragement. It is not so much perhaps what a nurse should do as what she should not do in the exercise of her vocation which requires to be instilled into her mind. Quick at perception, though hasty in judgment—which, however, is often intuitively correct,—and possessed of that gentleness of manner which has always been the admiration of both doctor and patient, it behoves a woman to acquire the broad principles which underlie the perfection of nursing in practice. Let us take, for example, the case of a patient insensible from an attack of apoplexy, or faint unto death from loss of blood owing to a ruptured varicosed vein. A nurse may possibly, in the absence of a medical man, be the first to be called upon to use discretion as to what is best to be done in the face of impending death; and that being so, we imagine no one will gainsay the advantage of such persons being possessed of so much anatomical and physiological knowledge as will not only suggest the proper course to be pursued, but will supply the *rationale* of the act. If a nurse has learned that the valves of dilated veins may be rendered functionless, so that the blood can under certain conditions—rupture for example—flow in either direction, she will be something more than a mere machine: she will have interest in her work, and interest begets efficiency. So, too, if she understands that any mental or physical excitement increases the frequency, and usually also the force, of the heart's beat, and that such increased action tends to expel more blood from a ruptured cerebral vessel, she will be doubly careful to avoid needless moving of the patient. For these reasons we hail with pleasure the information that in several of our London hospitals it has become an established usage for the authorities to organise, and the staff to carry out, a course of professional lectures to the female nursing staff. The undertaking has our hearty sympathy. At the same time we would express our opinion that it be an instruction to the audience that the scientific facts communicated to them are not to enable them to supplant the medical attendant, but to show them how they can be best subservient to him, and so most helpful to the patient.

THE VACANT CORONERSHIP IN BUCKS.

THE sudden death of Mr. Robert De'Ath, as announced in our last week's issue, has rendered vacant the office of Coroner for the Winslow Division of the County of Bucks. His son, Mr. George H. De'Ath, L.R.C.P.Lond., M.R.C.S.Eng., is a candidate for the post, and is to be opposed by a local solicitor. It is hoped and believed that the personal merits and professional attainments of Mr. De'Ath will secure his succession to the important office of coroner, for which his medical education and training eminently qualify him. The election rests with the freeholders of the county.

THE COMPLAINT AGAINST A HOSPITAL.

AT an inquest held at St. Thomas's Hospital last week, the jury appended to their verdict of accidental death the following rider:—"We are of opinion that there was great want of attention on the part of some of the officials at the hospital in not admitting the deceased on the Monday, and in keeping him six hours on the following day before attending to him." At first sight this appears a serious accusation against the staff of the hospital, but on inquiry we find that there is no reason for the censure. The patient first applied for relief two days after a fall in the street whilst drunk. He complained of headache; there was a small superficial scalp wound on the back of the head; no inequality of the pupils, no elevation of temperature, or other sign of serious injury to the head. An aperient draught was administered, and he was told to apply for admission next day if unrelieved. He applied with other patients next morning, and was admitted by the resident assistant-surgeon before twelve o'clock. He was then quite sensible, and in fact continued so for two or three days afterwards. As there was doubt as to the nature of the case, and no indications for immediate treatment existed, he was left until the surgeon visited the ward in the afternoon. The house-surgeon, who gave evidence at the inquest, was dismissed by the coroner, and no complaint against the hospital was brought under his notice. The inquest was held in a room in the hospital (by the kindness of the authorities), and no one was asked to reply to the charges made, the first intimation of which obtained by the hospital authorities being the publication of the proceedings in the daily papers. This is not the usual course adopted by juries, and it is not right that the staff of a hospital should be subjected to censure without being permitted to reply, or to protest, until the chance of effectual protest has passed.

POLLUTION OF THE LEA.

A FURTHER public meeting on this subject was held at the Hackney Town Hall on Monday last, when, on the motion of the Attorney-General, a resolution was unanimously passed expressing approval of the action of the Hackney District Board of Works in promoting the River Lea Purification Bill. Mr. Russell stated that after consultation with Mr. Gladstone and the President of the Local Government Board he should move for a committee to inquire into the question of the pollution of the Lea, without going into the larger question of river pollution generally. He believed that the easiest remedy would be for the Tottenham sewage effluent to be received into the sewer at Springhill, and thence into the sewer at Old Ford. But the latter is the property of the Metropolitan Board of Works, and it is evident that if this course be forced upon this Board by Parliament it will have to consider similar claims from other extra metropolitan districts. It is, however, so obviously the solution of the difficulty that we cannot but wish the Bill success.

THE REACTION OF LIVING NERVE TISSUE.

THE reasons why some drugs act upon one part of the nervous system more than on another have never been satisfactorily explained. Ehrlich has endeavoured to ascertain why it is that some staining reagents colour nerve fibres and others do not. He thinks the variation in alkalinity of different parts of nervous tissues and modifications in the state of impregnation with oxygen are two factors that regulate the absorption of foreign substances by nervous tissues. The degree of alkalinity and the quantity of stored intra-molecular oxygen depend no doubt upon the amount of work that the nervous tissue has just previously performed; probably the nervous structures are most alkaline, and contain the largest store of oxygen after a period of repose. Ehrlich suggests that such considerations may have a great importance in the study of the diverse actions of alkaloids.

ANOTHER FATAL FOOTBALL ACCIDENT.

WE regret to have to record yet another death from football. Thomas Radford, aged twenty-five, collier, of Skegby, Notts, died on Tuesday last from the effects of injuries received while playing at football. The deceased, who was a well-known player, was engaged as substitute with a Sutton team in a match against the Nottingham Castle Rovers. During the game it is stated that he was kicked in the abdomen by another player, and although at once attended to by a medical man, his injuries terminated fatally on Tuesday. This is the seventh fatal accident at football we have recorded this season.

CRYPTOMAINES.

EDIBLE mushrooms may under certain circumstances develop highly poisonous principles. On this supposition may be explained the occurrence of accidents from ingestion of the ordinary salutary fungi. These principles have varying degrees of poisonousness. Those cryptomaines that are extracted by chloroform appear to possess the greatest toxic power; the ethereal extracts come next; then follow the resinous parts and the amylic alcohol alkaloids. The chloroform cryptomaine and the resinous parts alone possess convulsant properties. Such are the conclusions of M. Houdé.

THE NEW BUILDING OF THE LONDON COLLEGES OF PHYSICIANS AND SURGEONS.

HER MAJESTY the QUEEN has graciously consented to lay, on March 24th, the foundation stone of the building to be erected conjointly by the Colleges of Physicians and Surgeons on the Thames Embankment. We congratulate the Royal Colleges on the signal honour thus conferred on them, and, through them, on "the republic of medicine," by Her Most Gracious Majesty.

HESLOP MEMORIAL.

A MARBLE bust of the late Dr. Heslop has just been placed in the library of Mason College, Birmingham, by the professors and students, in testimony of their gratitude for his truly princely and enlightened liberality to their *alma mater*. The sculptor, Mr. W. J. Williamson, of Esher, is to be congratulated. An admirable work of art, the bust is, if possible, still more remarkable and satisfactory as a perfect likeness of a typically fine head.

FIVE CHILDREN AT A BIRTH.

DR. V. TEYXEIRA reports in the *Gazzetta degli Ospitali* (21st inst.) that a woman in the seventh month of pregnancy was delivered of five living children—two females and three males. Three had died, and two seemed in a hopeless state at the date of report. The mother was progressing fairly.

THE second session of the French Surgical Congress will be held in Paris from the 18th to the 24th of October in the present year. The opening meeting will take place in the large theatre of the École de Médecine. The success which attended the first congress encourages the committee to expect from this second reunion of French surgeons results most favourable to the advance of surgery in that country.

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during January, it appears that the Thames water sent out by the Chelsea, West Middlesex, Southwark, and Lambeth Companies contained somewhat less organic matter than in the previous month; whilst the Grand Junction Company's water exhibited a slight increase in this respect, the proportion of organic matter present in all the samples being about the average of what is generally met with in river waters at this season of the year. The water drawn from the Lea and distributed by the New River and East London Companies exhibited a marked improvement as regards organic matter upon the previous month's samples. All the waters were delivered in a clear and bright condition.

ONE of the chief answers to Sir Crichton Browne's charges against the Education Code of this country was that in Germany, where the children were put to a more severe test than here, over-pressure was a thing never thought of. Dr. Roth, however, has now published some statistics which completely refute this argument. According to these figures, 64 per cent. of the scholars "who should work up to graduation are much below the normal standard of health." In Denmark, where a still higher standard of education is insisted on, a Government investigation brings to light the fact that 29 per cent. of the boys and 41 per cent. of the girls suffer from over-pressure.

THE movement which we inaugurated in London two or three years ago on behalf of the female shop assistants has been at length taken up by the Parisians. A committee of ladies in Paris are endeavouring to induce the proprietors of some of the large drapery and mercery establishments to allow seats for their female assistants. Females of mature age and young girls, indifferently, at some of the large shops in that city, have to attend from eight o'clock in the morning to the same hour at night with absolute orders that they are not to sit down whilst at their counters.

THE Port of London Sanitary Committee of the Corporation of London, which has the control of the sanitary and quarantine arrangements of the Thames, from Teddington Lock to the Nore, have, it appears, just made an urgent appeal to the Home Secretary upon the subject of the sewage of London, asking him to use his influence with the Metropolitan Board of Works to induce them to take prompt action in regard to providing a permanent remedy for the existing condition of the river through the outfalls at Barking and Crossness.

THE work of the French medical schools appears to be steadily decreasing. The whole number of diplomas given by six medical faculties in France was 662 for the year 1882-83, 590 for the year 1883-84, and 575 for the year 1884-85. The falling-off is mainly in those granted by the Paris faculty, while the schools at Lyons, Montpellier, and Nancy have shown a slight increase.

"The Human Brain; its Anatomy, Physiology, and Pathology," is to be the subject of three free lectures at Queen's College, Birmingham, on the 17th, 24th, and 31st March, by Professors Bertram Windle and Berry Haycraft, and Mr. E. B. Whitcombe.

A SCIENTIFIC society at Haarlem has offered a gold medal and 400 florins for the best treatise on the researches of M. Pasteur. The works, which may be in English, are to be sent in before April, 1887.

DR. GEORGE JOHNSON, F.R.S., has expressed his desire to be relieved, at the end of the present session, of the active duties of his offices as Professor of Clinical Medicine in King's College and Physician to the Hospital, and the Council of King's College has appointed him Emeritus Professor in the College and Consulting Physician to the Hospital.

AT the meeting of the Academia Médico-Quirúrgica Española on Jan. 12th, Señor Ustariz described a successful case of ligature of the subclavian artery with a catgut ligature prepared with corrosive sublimate for an axillary aneurysm of the size of an orange. The patient left the hospital cured fifteen days after the operation.

IT is reported that proceedings are about to be instituted in Germany against a number of persons styling themselves "Doctor" on the strength of diplomas purchased from America *in absentiâ*. In Berlin alone there are said to be 3400 of these "doctors," either of medicine, philosophy, or law.

WE understand that the annual course of lectures on Medical, Surgical, and Obstetric Nursing has just commenced at St. Mary's Hospital. A lecture is to be given every Tuesday, at 5 P.M. The course is not confined to the nurses of the institution, but is open to ladies generally.

HERR v. GOSSLER, medicinalrath, has announced that from next summer students in Prussian universities must undergo instruction in vaccination, and that especial attention is to be paid to vaccination with animal lymph.

WE regret to have to have to record the death of Mr. J. C. Wordsworth, F.R.C.S., on the 22nd inst., at the age of sixty-three. We hope next week to publish a brief account of the principal events of his professional career.

A FUND has been started in Paris with the object of promoting experimental researches for the cure of tuberculosis. More than 4000 francs have been subscribed. Subscriptions may be sent to M. Masson.

NEWS has been received at Portsmouth of a further outbreak of yellow fever on board H.M.S. *Urgent* at Jamaica, resulting in all in seven deaths, one of the victims being the ship's surgeon.

THE resignation is announced, after twenty-five years' service, of Dr. Baranowski, Professor of Therapeutics and Medical Diagnosis in the University of Warsaw.

DR. DON SALUSTIANO FERNANDEZ DE LA VEGA, Professor of Anatomy, has been appointed Dean of the Medical Faculty of the University of Zaragoza.

INTELLIGENCE has been received of the death of Dr. James Archibald Sidey, surgeon of H.M. Prison, Edinburgh, at the age of sixty-one.

THE fifteenth Congress of the German Surgical Society is to be held in Berlin from the 7th to the 10th of April.

HAMPSTEAD HOME HOSPITAL.—At the fourth annual meeting in connexion with this institution, on the 20th inst., it was stated that the number of patients during the past year was 71. The income amounted to £1093, and the expenditure to £1068. The patients' payments amounted to £592.

VAGINAL HYSTERECTOMY FOR CANCER.

THE October number of the *Bulletins et Mémoires de la Société de Chirurgie de Paris* contains an important communication by Professor Trélat, based upon a case in which he successfully removed the uterus through the vagina of a patient aged thirty-eight, referred to him by Professor Tarnier. Madame B——was the mother of six children, of whom the youngest was four years old. Uterine trouble had existed for some time, when both consultants, at the beginning of June, diagnosed epithelioma in its early stage, involving the whole surface of the neck of the womb, but not deeply. The vaginal mucous membrane was perfectly healthy, and careful examination failed to detect any glandular enlargement. The uterus was mobile, but considerably enlarged; the hysterometer introduced into its cavity reached 9 centim.

M. Trélat considered the case in every respect favourable for operative intervention. The lesions were limited and recent, the uterus very movable, and the operation was desired by the patient and relatives. In weighing the question of supra-vaginal amputation of the cervix and total removal of the organ, the following considerations presented themselves. Amputation of the cervix is, as a rule, considered less serious, but it is a blind operation. When it is performed, it is impossible to say if the pathological limits have been passed, and, if so, how far. It is, on the other hand, certain that the mortality from vaginal hysterectomy has been lately much reduced, and that it is reasonable to assume that the risk of recurrence will be less after total than after partial removal. In this case the operation was performed on July 2nd. For several days the vagina and uterus were washed out with bichloride of mercury solution, and the rectum and bladder were evacuated before the patient was anæsthetised. Sims' speculum having been introduced posteriorly, the cervix was brought down by seizing with forceps the anterior and posterior lips. A semicircular incision having been made anteriorly into the vaginal mucous membrane, the bladder was detached quickly and easily. The finger introduced into the wound separated the peritoneum without penetrating into the peritoneal cavity. Drawing the uterus backwards and the fundus of the bladder forwards, the peritoneum could be seen as a bluish membrane, which was seized with forceps, incised with scissors, and with the fingers freely separated as far as the sides of the uterus. The cervix having then been drawn forwards, the same manœuvre was repeated on its posterior aspect—incision of the mucous membrane, detachment, section, and laceration of the peritoneum as far as the broad ligaments. The speculum having been withdrawn, the uterus was again brought down by continuous and energetic traction. Two fingers introduced posteriorly failed to reach the fundus in consequence of the height of the womb. After considerable difficulty, the right broad ligament was brought into view, tied, and divided. The ligature having slipped, the Fallopian tube and the different vessels were tied separately. A similar procedure was practised on the left side, but proved very tedious. Bleeding had then been arrested, and at the bottom of the wound could be seen the left ovary, an omental fringe, and a coil of small intestine; but nothing protruded through the vagina. This and the bottom of the wound were carefully cleansed, and the lips of the vaginal wound were united by a single suture. In each angle of the wound was placed a drainage-tube as thick as a good-sized writing-quill, penetrating from 2 to 3 centim. into the peritoneal cavity, and projecting beyond the vulva. Around the tubes the vagina was plugged with iodoform gauze, the extremities of the tubes were abundantly surrounded with the same kind of gauze, and the whole covered with a thick layer of cotton-wool as far as the flannel body bandage, also lined with cotton-wool. The patient, still sleeping, was then taken back to bed.

The extirpated uterus was so large as to seem gravid. It weighed 197 grms., was 11 centim. in length, 64 mm. in its greatest breadth, and 45 mm. thick. Each wall was 17 mm. thick. To the naked eye the cervix was manifestly the seat of epithelioma. Section of the uterus on a level with each broad ligament appeared absolutely healthy, and proved so under the microscope. The histological examination was simultaneously conducted in the laboratories of La Charité and of the Collége de France, with identical results. The cervix was occupied throughout its whole extent with a superficial, tesselated, lobular epithelioma. A section through the whole height of the cervix proved that only the lower third of the section was involved. The upper part was absolutely healthy. The great size of the body of the organ was due to simple hypertrophy of the uterine tissue. The broad ligaments were quite healthy.

The patient's progress was most satisfactory through an uneventful and rapid convalescence. In the evening of the day after the operation, the external dressing, soiled with sanguineous discharge through the drainage-tubes, was changed; only the odour of iodoform was perceptible. Urine passed with increasing freedom. Temperature 38·4°; pulse 120. After a good night the patient enjoyed some iced consommé and champagne, and passed gas per anum. The outer dressings were again changed, and the external organs washed with sublimate solution. Temperature 37·8°; pulse 94. The third day after the operation one drainage-tube and the vaginal dressing were removed, the latter being renewed after washing with bichloride solution. The second tube was withdrawn and the same dressing renewed on the fifth day. The day following the bowels responded freely to two castor-oil capsules, and they acted naturally on July 9th (seventh day). The patient was now allowed beefsteak, Bordeaux, and port wine, and all dressing was removed. A little pus was seen on the vaginal tampon of iodoform gauze. The vagina was injected with sublimate solution; as this caused some irritation, it was resolved to use chlorinated water in subsequent injections. The vaginal sutures passed away with the injection on the eighteenth day, and on examining the passage carefully with the speculum on the twenty-first day the cicatrix was visible as a transverse solid line. The patient left her bed comfortably on the twenty-third day, and continued to progress favourably.

In the discussion which followed, Dr. Terrier, after recalling a case, previously communicated to the Society of Surgery, in which he had successfully removed the uterus through the vagina for cancer of the cervix, referred to a second case of similar operation, which proved fatal on the sixth day in consequence of intra-peritoneal hæmorrhage.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Braintree Rural District.—The birth- and death-rates for this district during the past year were 26·2 and 17·8 per 1000 respectively, the so-called zymotic rate being 0·97. Mr. Abbott presses upon his authority the need for means of isolating first attacks of infectious diseases, and refers to experience in connexion with the Doecker huts. A small permanent hospital is, however, far better, for it is not always easy on the spur of the moment to get an available site, and the most valuable moments have often been lost where these temporary structures have been relied upon. If this rural district had expended all that it has paid for temporary hospital work at such places as Terling and Coggeshall on a small brick building, it would be far better off than it is now in this respect. The experience cited below as to the Brentford urban district illustrates our meaning opportunely, and we should advise Mr. Abbott and his authority to consult the plans of small permanent hospitals issued by the Local Government Board last year as a way out of the difficulty. Some defaults of drainage and of water-supply are still in need of a remedy, and in certain localities rain-water storage seems to be the only feasible plan to adopt. With slate-roofs and the rain-water separators which were shown in the International Health Exhibition, and by which the dirt from the first washings of the roof is prevented from passing into the storage tank, rain-water can be often resorted to without the risk of an objectionable deposit at the bottom of the tank which necessitates such frequent cleansings. Much is being done to improve the water-supply where springs are available, and at Bradwell considerable benefit has already resulted.

Brentford Urban District.—The work of connecting the

Digitized by Google

houses with the new system of sewers, and of abolishing cesspools by filling them up, is steadily continuing in this district, and it has already been effected as regards 2230 out of a total of about 2500 dwellings. In view of complaints as to offensive emanations from the sewer ventilators, the plan of carrying additional shafts to a height above the houses and of securing systematic and frequent flushing has been resorted to, and so far with the prospect of success. During the past year a number of closets have been supplied with cisterns separate from those from which the domestic supply is drawn. This is a most important point, and since it is so easily effected, as by the fitting up of a waste-preventing and automatic flush cistern just above the closet, it is to be regretted that the improvement is not more generally adopted in all districts. Adverting to what we have so often said as to the drawbacks attaching to temporary infectious hospitals, we would quote what Mr. Williams writes: "No site has yet been found upon which our portable hospital can be erected ..... Should an epidemic arise we should be in a difficulty." We commend our remarks made upon the Braintree rural district to Mr. Williams. Inspection of dwellings and nuisance abatement form important features of the year's work, and the summary given is a satisfactory one. The birth-rate for 1885 was 38·5 per 1000, and the death-rate 16·6 per 1000. The latter compares well with many surrounding districts.

Montrose Sanitary District.—The corrected death-rate for this district during 1885 was 19·2 per 1000, and it was satisfactory in so far as it exhibited a decrease on the previous year, and because it was but little made up of diseases belonging to the infectious group. Uncertified deaths lead to uncertainty in the vital statistics, and with Dr. Laurence we wish some further control could be properly exercised in this matter. The report gives hardly any information as to the conditions under which the people live, as to the remedies necessary to be taken to improve the sanitary circumstances, or as to action taken in this direction during the year. It is rather a statistical than a "health" report.

Watford Urban District.—Diphtheria continues to cling to this otherwise attractive residential town. From 1850 to 1877 it was, according to Dr. Brett, a rare disease in Watford; but since then, although there has been no extensive prevalence of the disease till last year, it has off and on recurred. In 1883 it caused 6 deaths, 5 deaths in 1884, and 29 deaths in 1885; the largest mortality in the latter year taking place in the colder months. All the elementary schools suffered, but, so far as is known, none of the private ones were affected, and no case occurred in the neighbouring London Orphan Asylum, a circumstance worth noticing, because, though not in Watford district, yet this institution is connected with the town system of sewers. Recently Mr. Sweeting made an inspection of this district in connexion with the diphtheria prevalence, and his report to the Local Government Board is awaited in the locality. The system of sewer-ventilation has been credited with much of the mischief, but Dr. Brett is inclined to think that this view is erroneous. There are 169 ventilators mostly opening on to the crown of the road, and many have been found to be useless because they were blocked with road detritus, a result which is clearly due to inadequate inspection on the part of the local authority. Improvements are needed in Watford at the market-place, and by substituting a constant for the intermittent service of a water which is excellent in point of quality. A systematic effort is also needed to improve the courts and alleys in the older part of the town. The deaths for the year were at the rate of 17·3 per 1000. Apart from diphtheria, there was but little sickness and few deaths from any of the infectious fevers.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6061 births and 4265 deaths were registered during the week ending February 20th. The annual death-rate in these towns, which had been equal to 22·1, 22·2, and 23·1 per 1000 in the preceding three weeks, further rose last week to 24·4. During the first seven months of the current quarter the death-rate in these towns averaged 22·9 per 1000, and was 1·9 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 15·8 in Birkenhead, 16·4 in Leicester, 17·6 in Derby, and 18·1 in Sheffield. The rates in the other towns ranged upwards to 30·0 in Plymouth, 30·7 in Sunderland, 32·7 in Halifax, and 39·1 in Blackburn. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 360, 376, and 405 in the preceding three weeks, further rose last week to 425; they included 197 from whooping-cough, 70 from measles, 43 from diarrhœa, 39 from diphtheria, 33 from "fever" (principally enteric), 31 from scarlet fever, and 3 from small-pox. These zymotic diseases caused the lowest death-rates last week in Preston and Norwich, and the highest rates in Portsmouth, Bolton, and Blackburn. Whooping-cough caused the greatest mortality in Portsmouth, London, Bolton, and Cardiff; measles in Portsmouth, Plymouth, and Blackburn; scarlet fever in Leeds; and "fever" in Birkenhead. The 39 deaths from diphtheria in the twenty-eight towns included 19 in London, 3 in Birmingham, 3 in Liverpool, 2 in Bristol, 2 in Birkenhead, and 2 in Oldham. Small-pox caused but 1 death among the residents of London and its outer ring, 3 in Liverpool, and not one in any of the twenty-six other large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had declined in the preceding fourteen weeks from 90 to 11, were 10 on Saturday last; 2 new cases were admitted to these hospitals last week, against but 1 in each of the previous two weeks. The Highgate Small-pox Hospital contained 4 patients on Saturday last, one case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 479 and 584 in the preceding two weeks, further rose last week to 639, and exceeded the corrected weekly average by 98. The causes of 94, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Preston, Birkenhead, Cardiff, and in three other smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Oldham, Brighton, and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 21·3 and 24·5 per 1000 in the preceding two weeks, declined again to 22·3 in the week ending February 20th, and was 1·1 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 17·4 and 19·2 in Edinburgh and Leith, to 24·3 in Paisley, 24·6 in Perth, and 24·8 in Glasgow. The 551 deaths in the eight towns showed a decline of 55 from the number in the previous week, and included 16 which were referred to diarrhœa, 13 to whooping-cough, 8 to scarlet fever, 4 to measles, 3 to diphtheria, 2 to "fever," and not one to small-pox; in all, 46 deaths resulted from these principal zymotic diseases, against 32 and 53 in the preceding two weeks. These 46 deaths were equal to an annual rate of 1·9 per 1000, which was 0·5 below the mean rate from the same diseases in the twenty-eight English towns. The 16 deaths attributed to diarrhœa corresponded with the number in the previous week, and included 7 in Glasgow, 5 in Aberdeen, and 3 in Leith. The fatal cases of whooping-cough, which had been 9 and 17 in the preceding two weeks, declined again last week to 13, of which 10 occurred in Glasgow. The deaths referred to diphtheria and "fever" showed a decline from recent weekly numbers; 2 from diphtheria were returned in Aberdeen. Six of the 8 fatal cases of scarlet fever occurred in Glasgow, and all the 4 of measles in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 135 and 144 in the previous two weeks, further rose last week to 153, and exceeded by 14 the number returned in the corresponding week of last year. The causes of 66, or nearly 12 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had steadily increased in the preceding four weeks from 29·6 to 38·6, declined again to 31·8 in the week ending Feb. 20th. During the first seven weeks of the current quarter the death-rate in the city averaged 32·5 per 1000; the mean rate during the same period did not exceed 23·3 in London, and 18·3 in Edinburgh. The 215 deaths in Dublin last week showed a decline of 46 from the number returned in the previous

Digitized by Google

week, and included 20 which were referred to the principal zymotic diseases, against 26 in each of the previous two weeks; 16 resulted from whooping-cough, two from "fever" (typhus, enteric, or simple), 1 from measles, 1 from scarlet fever, and not one either from small-pox, diphtheria, or diarrhœa. These 20 deaths were equal to an annual rate of 3·0 per 1000; the rate from the same diseases last week did not exceed 2·7 in London and 1·2 in Edinburgh. The fatal cases of whooping-cough, which had declined in the preceding five weeks from 19 to 10, rose again last week to 16. The deaths from "fever," on the other hand, declined to 2 last week from 6 and 14 in the previous two weeks. Two inquest cases and 3 deaths from violence were registered; and 50, or nearly a quarter of the deaths, were recorded in public institutions. The deaths both of infants and of elderly persons showed a considerable decline from the numbers in the previous week. The causes of 37, or more than 17 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Brigade Surgeon Charles Hamilton Harvey, M.D., is granted retired pay, with the honorary rank of Deputy Surgeon-General. The undermentioned Surgeons on probation to be Surgeons:—Michael Thomas Yarr, Langton Philip Mumby, M.B., Charles Henderson Melville, M.B., Bernard Langley Mills, M.B., Hugh Rayner, M.B., Richard Edward Genge, George Schuyler Cardew, M.B., Charles Alan Renny, M.B., Herman Thiele, M.B., Horace Cocks, M.B., James Barnett Wilson, M.D., William John Lee, John Greer Black, M.D., John Kearney, M.D., Frank William Hennessy, M.B., Francis Albert Saw, M.B., Whitley Bland Stokes, M.B., Frederick William George Hall, M.B., Arthur Kennedy, George Scott Tate, M.D., Henry William Martindale Kendall, Henry Percival George Elkington, Robert Charles Gordon Dill, John Blacker Whitla Buchanan, M.B., Frederick Thomas Skerrett, Henry Mackenzie Adamson, M.B., Herbert Murray Ramsay, Tudor Germain Lavie, James Rose, Robert Hippisley Cox, Harry Herbert Brown, M.B., Thomas Herbert Corkery, Edward Hawke Locker, Warren Rolond Davies Crooke, M.D., Walter Perfect Squire, Charles Lawrence Walsh, James J. O'Donnell, M.B., Stanley John Wallace Hayman, and Julian Philip Swindell Hayes.

INDIA OFFICE.—The Queen has approved of the retirement from H.M. Indian Forces of the following officers:—Brigade-Surgeon G. Alder Watson, Bengal Medical Establishment; Brigade-Surgeon C. Robertson, M.D., Madras Medical Establishment; Surgeon-Major Henry Atkins, Bombay Medical Establishment.

The following officers are granted a step of honorary rank on retirement: Brigade-Surgeon Thomas Beaumont, M.D., and Brigade-Surgeon Charles Robertson, M.D., both of the Madras Medical Establishment, to be Deputy Surgeons-General. Surgeon-Major Malcolm Munro Mackenzie and Surgeon-Major Henry Atkins, both of the Bombay Medical Establishment, to be Brigade Surgeons.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon Henry Madders, M.D., to the *Emerald;* Staff Surgeon John K. Conway, M.D., to the *Liffey:* Staff Surgeon William B. Drew, to the *Himalaya;* Surgeon J. C. Dow, to the *Himalaya:* and Surgeons F. W. Stericker, J. F. Bate, W. F. Pryn, G. E. Kennedy, J. Barry, A. J. Pickthorne, E. A. Spiller, J. Andrews, E. Apthorp, H. J. Hadden, J. J. M'Donnell, J. G. Webb, V. G. Thorpe, M. H. Atock, G. W. Meaden, J. H. Dawe, to the *Duke of Wellington*, for service at Haslar Hospital.

Amongst the officers who left Portsmouth in the *Malabar* for India on the 24th inst. were Surgeon Thompson, Bombay Medical Staff; and Surgeons Munders, Butterworth, and Baylor, Medical Staff.

MILITIA MEDICAL STAFF.—9th Battalion, the Rifle Brigade (the Prince Consort's Own): Surgeon Robert Vandeleur Kelly to be Surgeon-Major.

RIFLE VOLUNTEERS.—2nd Volunteer Battalion, the Royal Welsh Fusiliers: Thomas Evans Jones, Gent., to be Acting Surgeon.—3rd Durham (the Sunderland): Acting Surgeon Charles Henry Welford, M.D., resigns his appointment.—2nd Volunteer Battalion, the Prince Albert's (Somersetshire Light Infantry): Acting Surgeon Rowland Hill West resigns his appointment.

Correspondence.

"Audi alteram partem."

RINGWORM OF THE HEAD AND ITS TREATMENT.

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 20th a "Portuguese" (?) treatment of ringworm is mentioned, and it is suggested that ringworm of the most obstinate character may be cured in ten days by using turpentine and iodine. As this notice may lead some to think this is a new way of treating this most troublesome complaint, I may remind such that it is an old treatment, and has been fully described.

So many treatments have been suggested—almost as specifics—for this disease within the last few years, that one is tempted to inquire whether their authors really know when this complaint is absolutely cured. From my own personal knowledge I know that many medical men both consider and certify ringworm to be cured when it is in a contagious state, and that we are fully justified in doubting whether many of the so-called "cured" cases are not in the condition I have so often called attention to before—viz., cases which have been treated until perhaps some new hair has made its appearance, but in which diseased, broken-off hairs are easily to be detected with a lens. I do not speak at random, but with the fullest experience and knowledge of the facts which warrant such a statement, when I say that there is not the least doubt that children are constantly sent back to school, even with a medical certificate stating the ringworm is cured, when the disease is in a most chronic, and certainly in a highly contagious, state. Many will hardly credit the number of children that are brought under my notice for admission into Christ's Hospital and into other schools, both public and private, who have had certificates given to them by medical men—often of the highest professional standing—that they are free from contagion, and who still have ordinary ringworm in its most common and chronic form. Even this year I have seen at least twenty such certified cases, and know that the principals of some schools have grievously suffered from these errors.

It is a very easy matter to decide whether a case of ringworm be cured or not (if sufficient time be given to the examination of the head), by the presence or absence of short, fragile, broken-off hairs, called stumps; and I cannot do better than quote the definition now adopted by the Medical Officers of Schools Association, and published by them in their "Code," in reference to this matter: "When may a pupil who has had ringworm rejoin a school?—When, the whole scalp having been examined in a good light, and any suspicious spot scrutinised with a lens, no broken-off stumpy hairs (which give evidence of the ringworm fungus when carefully examined under the microscope) are to be detected. It is sometimes considered that ringworm is cured when the hair commences to grow on the diseased places, but this is a mistake, for it frequently happens that diseased broken-off hairs remain, and the disease may thus exist for months or years. It is often very difficult to detect the short stumps which protude only a sixteenth or an eighth of an inch, and it is quite useless to examine short cut-off healthy hairs from a suspicious spot under the microscope for the ringworm fungus."

What I wish the profession to realise is that when remedies are said to cure obstinate ringworm in a week or two there must be a mistake somewhere; either the case was not one of tinea tonsurans at all, or else the disease cannot have been cured in such a short space of time, except by the application of strong caustics, which would cause scars, or by the production of kerion by croton oil or other means. It is impossible for the diseased stumps to be got out of the follicles and for new hair to grow from them in less than from six to twelve weeks. As a rule, lotions or ointments have to be assiduously applied for months before the case is quite well; and unless kerion has been set up it is not justifiable to certify a patch of ringworm to be cured until new hair has replaced the diseased stumps, for it is easy for these to be rubbed down on a level with the skin, and for the place to appear well to an unpractised eye. Diseased stumps do not suddenly grow up into healthy hairs, but they come out and are replaced by fine new downy

Digitized by Google

hairs; and even when these appear, it by no means proves the case to be cured, as there are generally a few diseased stumps left, which can easily be seen with a lens, their removal being most difficult, and sometimes impossible for months. Therefore, although most of the hair may be growing firmly and freely over a patch of ringworm, this alone does not prove the case to be cured.

With regard to the treatment by turpentine and iodine, though certainly a good one, yet I believe it will fail in the majority of obstinate cases. The plain truth is that there is no known remedy that is sure to eradicate any given case of ringworm, even after months of treatment; and sometimes children will have this complaint for years, though every means be taken to remove it. Oleate of copper and mercury, and all other remedies, often fail, in spite of what has been written to the contrary.

I am, Sir, yours obediently,

ALDER SMITH, M.B., F.R.C.S.,
Feb. 24th, 1886. Medical Officer to Christ's Hospital.

HOME *v.* HOSPITAL TREATMENT OF INFECTIOUS DISEASES.

To the Editor of THE LANCET.

SIR,—On January 23rd you drew attention in an annotation to the section of my Report on the Sanitary Condition of Bradford dealing with the above important subject. For reasons which will appear pretty obvious, I have given in my reports to the Town Council the rates, and not the actual numbers, upon which I founded my opinion that in Bradford the proportion of recoveries among those treated in hospital for certain infectious diseases is very much greater than among those treated at home. As you expressed a desire to have fuller information on the subject, I have much pleasure in laying the details before your readers.

TABLE SHOWING THE MORTALITY PER 100 CASES FROM SCARLET FEVER AND TYPHOID FEVER IN BRADFORD, WHEN TREATED IN THE HOSPITAL AND WHEN TREATED AT HOME.

Year.	Death-rate per 100 Cases.					
	Scarlet Fever.			Typhoid Fever.		
	Treated at home.	Treated in hospital.	All cases.	Treated at home.	Treated in hospital.	All cases.
1882	18·4	14·5	13·9	13·0	17·3	15·2
1883	15·8	7·3	10·3	32·6	14·2	22·1
1884	9·1	4·2	6·7	29·6	18·5	24·5
1885	8·3	3·9	5·9	42·1	6·3	19·80
Mean 4 years	11·7	6·82	8·95	27·7	14·1	20·44

As the compulsory notification of infectious disease has been in operation here over four years, already a considerable number of cases have been recorded on which to form an opinion. During 1882, 1883, 1884, and 1885 there have been 758 cases of typhoid fever and 2032 cases of scarlet fever. (I deal with these two as by far the most important diseases, the case of other diseases notified having been much too few to be of value for drawing any reliable conclusion from.) Of the cases of typhoid fever, 404 were treated in the hospital and 354 at home; the deaths among the former numbered 57, and among the latter 98, giving a death-rate of 14·10 per cent. for the cases treated in hospital, and of 27·68 for those treated at home. Of the 2032 cases of scarlet fever, 1143 were treated in the hospital (during the same period), and 889 at home; of the former, 78 died, and of the latter 104, giving respective rates of 6·82 per cent. deaths for the cases of scarlet fever treated in hospital, and of 11·69 for those treated at home; the number of cases of these two diseases dealt with is considerable, indeed very much larger than that frequently regarded as sufficient for using as the grounds for an opinion as to success in therapeutics, whether medical or surgical, and the numbers compared treated in hospital and at home are not markedly different. The period embraced—four years—is also one of considerable duration. In the case of scarlet fever the lower rate prevailed every year in the hospital; the rate for typhoid was a little higher in the hospital for the first year (1882), but during each succeeding year the advantage has been very much on the side of the hospital. These particulars will be seen at a glance in the table given below.

The explanation which you suggest of these facts—viz., that the home-rate is increased by the suppression of notification of mild cases—is, I think, not warranted. So far as concerns notifications sent by medical men I am perfectly satisfied it is erroneous. I have every reason to believe that every member of the profession continues loyally to carry out the anxious and troublesome duties cast on him by the Act requiring notification. It would be expecting greater certainty than prevails in any human affairs to expect that no case unattended by a medical man ever escaped notification. There may be some few which do, I think there are not many. But even allowing for such cases, the difference between the hospital rate and the home rate is so great that it cannot reasonably be thus accounted for. The latter is pretty nearly double the hospital rate for both scarlet fever and typhoid. With regard to the character of the cases sent into the hospital, some are sent in because they are very severe, others are kept at home for the same reason—viz., that they are too ill to be moved. Again, some cases may be sent into hospital which are exceedingly mild and only need isolation; but for the same reason many mild cases are treated at home because of the slight character of the symptoms. I am informed by Dr. S. Evans, the resident physician at the Fever Hospital, that if the severe cases sent to the hospital which die within twenty-four or forty-eight hours of being received there were deducted from the hospital figures the result would be to show a very great reduction in the hospital rate. Such cases can hardly be said to have undergone treatment at the hospital at all, although they increase the death-rate recorded in the institution, and lower the proportion of deaths at home, I think, indeed, the explanation of the more favourable returns from the hospital is not far to seek. Perhaps 97 per cent. of the cases occur among the poorer class, fully 96 are distinctly of this class, and of these a large proportion are of the poorest class. There is no doubt excellent professional skill available for their treatment at home; but of what use can this be in small crowded rooms, where fresh air, were it available, is not admitted, situated as workmen's houses usually are, and without the skilled nursing, constant care and supervision, and abundant and suitable dietary which the hospital can provide? If the acute stage of the fever be tided over, there remain the difficulties attending convalescence, which are not small in the case of the two diseases I refer to. But these are only matters of opinion. I have given the facts as fully as possible, so that your readers may judge whether my strong advocacy of hospital treatment in this town is well founded or not.

I am, Sir, your obedient servant,

Town Hall, Bradford, Feb. 8th, 1886. T. WHITESIDE HIME.

ENTERIC FEVER.

To the Editor of THE LANCET.

SIR,—After reading the interesting discussion at the Royal Medical and Chirurgical Society on Enteric Fever at Suakim (THE LANCET, Feb. 13th), I thought that a few notes gained from my experience in South African warfare might not be unacceptable; the subject can be read more in detail at page

Digitized by Google

513 of the Transactions of the International Medical Congress of 1881. In the Kafir war of 1877 I was principal medical officer of the Naval Brigade, and in 1879 I was principal medical officer of the Column of Invasion commanded by Brigadier-General Sir C. Pearson, K.C.M.G., C.B., during the Zulu war, and I thus had ample opportunities of seeing a very large number of cases of both enteric and the so-called typho-malarial fever. I must say that I entirely agree with those authorities who are of opinion that the disease frequently arises *de novo*. During our investment by the Zulus in Fort Ekowe, from Jan. 23rd to April 4th, 1879, we were entirely cut off from all communication with the outer world, except that very rarely a solitary Kafir runner managed to creep through the investing Zulu army from our base of operations some forty miles away on the Natal frontier. Before the march of our column from this base of operations no case of enteric fever had been heard of there; neither was the disease known at the mission station of Ekowe before our arrival there, as I ascertained from a medical missionary who was an old resident. The earliest case of enteric fever occurred among the garrison of Ekowe about the end of the first week in March, and no runner came there from the base in Natal after the 12th of February; it was, moreover, a considerable time subsequent to that date that any case of enteric fever was heard of at the base in question. There were many cases of enteric and typho-malarial fever at Ekowe, including several deaths. Thus it will be seen that it is as nearly proved as anything of the kind can possibly be that the affection must have arisen *de novo*, unless the very dubious hypothesis is advanced that the provisions with which we were supplied contained the germs.

I believe that the cause, in these countries at least, is generally to be sought in the prolonged occupation of a camping-ground, and that the term "pythogenic" is a very happy one. I am of opinion that flies are great factors in its production; they swarm in latrines and cesspits, where the heat favours decomposition, and arise from them often with their fine hairs coated with putrescent matter, shortly to be deposited on articles of diet, or in potable fluids, in which they are often found drowned. The fine surface impurities of these camps are also wafted by the winds into the tents, covering the food and potable water, or being inhaled or swallowed with the saliva. I do not remember ever seeing a case of enteric fever which occurred in an active flying column, which is of course constantly changing its camping-grounds or perhaps merely bivouacking at night, or for some considerable time after such a column had become stationary; but whenever the disease appeared it was invariably in a camp of some permanency, where decomposition of animal matter and frequently malaria coexisted in a subtropical heat.

The colonial surgeon of the Lower Tugela Division of Natal, in which our base of operations was situated, informed me that he had never seen a case of enteric fever in his district until the advent of our troops in 1879; and he told me, a year and a quarter after the troops were withdrawn, that since their departure not a single case had been brought under his notice.

I witnessed several necropsies of cases of so-called typho-malarial fever, and, so far as the morbid appearances were concerned, they were strictly identical with those of ordinary enteric.

I am Sir, yours truly,

HENRY F. NORBURY, C.B.,
Fleet Surgeon R.N.

Plymouth, Feb. 18th, 1886.

INVERSION OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—In THE LANCET for Dec. 26th, 1885, is a very interesting case by Dr. Arbuckle of the reduction of chronic inversion of the uterus by the combined method of incision of the cervix and sustained elastic pressure. Dr. Arbuckle does me the honour to cite me as the author of the treatment by incision. Dr. Neale in a subsequent number quotes his valuable "Digest" to show that "Dr. Pratt of Fife contributed a paper to the *Medical Times and Gazette* in 1868, in which he asserts that Dr. Wasseige of Liege is the sole originator of this most effectual plan." As I should be sorry to let it appear that I could in any way wish to appropriate merit due to others, I must beg of you to give me the opportunity of presenting the following explanation. I have not been able to find the memoir of Dr. Wasseige referred to by Dr. Pratt, nor do I find "Dr. Pratt of Fife" now on the Register; so that I have no means of verifying the terms or the date of Dr. Wasseige's communication. Perhaps some of your readers may help me. But, in truth, the question of originality is not to be determined by reference to Dr. Wasseige or to Dr. Neale's "Digest." This work is almost limited to noting contributions to three medical journals, and cannot be accepted as an authority upon this or similar questions. If Dr. Neale had extended his researches beyond this range, he might have seen that I have not claimed priority in the idea of incising the cervix for the reduction of inversion. In my memoir in the Medico-Chirurgical Transactions (1869), after discussing the various methods in use, is the following passage:—"Another proceeding stands before amputation. For twenty years I have taught in my lectures that the unyielding cervix may be divided by incisions carried into its substance from above downwards at different points of its circumference. Pressure thus applied will cause it to yield more easily. Huguier, Professor Simpson, and Dr. Marion Sims have suggested the same plan. I am not aware that it had ever been carried into execution before 1868, when I treated a case in this manner with complete success." The case is narrated in the memoir. I published another successful case in the *Obstetrical Journal* (1873), and I have had since at least one more in St. George's Hospital. Other cases are recorded.

Aran's "Maladies de l'Utérus" (1858-60) has the following passage: "Reste à savoir, cependant s'il ne peut pas se trouver des cas dans lesquels la rigidité du col serait à son tour un obstacle à la réduction; je préfèrerais alors, je l'avoue, le débridement du col pratiqué avec prudence, à l'aide d'un bistouri boutonné, sur la commissure de l'orifice, voire même le débridement multiple." It is to be noted that Aran does not say he has done it, nor does he describe a case.

Thus, so far as my actual information goes, the case stands as I put it in 1869. Although I did not claim priority of publication of the plan of incising the cervix to facilitate reduction of inversion of the uterus, I did claim to have been, as I know, the first who had successfully practised it as an aid to reduction by sustained elastic pressure.

The most memorable discovery in the history of inversion of the uterus is that of Tyler Smith, who first (Medico-Chirurgical Transactions, 1858) successfully demonstrated the method of reduction by sustained elastic pressure, and who thus removed what had hitherto been an *opprobrium chirurgicorum*.

I am, Sir, yours truly,

ROBERT BARNES.

Harley-street, Feb. 1886.

THE TREATMENT OF DOG BITES.

To the Editor of THE LANCET.

SIR,—It has always seemed to me that it was beginning at the wrong end to pay so much attention to hydrophobia and entirely to overlook the treatment of dog bites. It is unnecessary now to plead the cause of the germ theory. Pasteur has shown that this disease is caused by germs, and that poisonous germs exist even in human saliva. The hydrophobia germs are inoculated by the teeth of the dog; why not, therefore, destroy the germs in the wound by some antiseptic? I do not speak against the method of counter-inoculation, or the wonderful skill and vast knowledge of the founder of the germ theory, but I advocate prevention instead of cure. The ordinary treatment of dog bites is unscientific. There is, first, the do-nothing treatment, based on the erroneous idea that free bleeding purifies the wound. Neither blood nor any other fluid could mechanically cleanse an inoculated ragged wound. I have noticed two cases treated in this way followed by hydrophobia. Secondly, applying mild caustics, as nitrate of silver. Though very fatal to the mould plant, it is not an antiseptic; moreover, as soon as it is applied to a wound there is a precipitation of the chloride, which is white, and silver, which is black, both of these being insoluble and inert. Thus, the only effect is to seal the germs in the deep part of the wound with a slight caustic action on the surface. This treatment is commonly followed by hydrophobia. Thirdly, immediate excision or application of some strong caustic, as fuming nitric acid. These being severe methods are not often resorted to.

The most rational treatment of a dog bite is to apply some germicide or antiseptic which will penetrate the tissues without coagulating them. The theory is perfect; therefore failure would only be due either to delay or insufficient

Digitized by Google

application. The antiseptic used is a matter of detail and sometimes of circumstance. I usually employ a solution of one part of carbolic acid to four or five parts of glycerine, for the following reasons: It is a reliable germicide; it is not a caustic; it penetrates the tissues, the glycerine having an attraction for water, and thereby carrying the antiseptic to the deeper parts of the wound. Probably it passes into the lymphatics, as it is sometimes followed by glandular pain; if so, it is doubly valuable as a germicide. I paint the wound every day till it is healed. By this method the wounds heal without inflammation, leaving a pale, contracted, healthy cicatrix. In 1878 I treated three children that had been bitten by a rabid dog; they were all bitten in the back of the leg; as they walked to school the dog ran in the same direction. They all did well. I inserted pellets of wool soaked in glycerine carbolic into the holes made by the canine teeth. I have noticed some dog-bite scars which have never been treated. They have been purple and bulging; as that is an unhealthy appearance, I excised with antiseptics, obtaining pale, contracted cicatrices. I saw a case of hydrophobia last year. The wound, which had been treated with nitrate of silver, had left a purple and raised scar. The dog was supposed not to be rabid. This opens up a very wide question as to whether hydrophobia can be caused by a non-rabid dog. It is interesting to observe that, in whatever part of the body the germs are inoculated, they find no resting-place till they reach the salivary glands, which form their natural soil. As no single method of treatment has ever cured hydrophobia, rational experiments are legitimate. The snake poison lately proposed seems rational. I would suggest also a rational experiment: rapid and profuse salivation by pilocarpine or jaborandi, followed up by small doses of corrosive sublimate, which latter, as well as salivating, would act as an antiseptic in the blood. If the subject of hydrophobia were ventilated in THE LANCET before the hot season begins, it might be productive of much help to those who in the coming summer may be called to treat cases.—I am, Sir, yours, truly,

Leytonstone. ALBERT WILSON, M.D.

THE TREATMENT OF PERTUSSIS.

To the Editor of THE LANCET.

SIR,—I have read the letters of Messrs. Cory and Kerr in THE LANCET with much interest, and I congratulate them upon their success in the treatment of whooping-cough by carbolic acid. Allow me, however, to point out that carbolic acid is recommended internally and by inhalation to lessen the spasm by Dr. Wm. Squire in his article upon Whooping-cough in "Quain's Dictionary of Medicine." It is difficult for one to believe that carbolic acid given in the usual medicinal doses can have any power in stopping the progress of the disease, for I believe it is now generally held that whooping-cough is caused by specific pathogenic organisms, and Koch has clearly shown by experiment that it requires from ·25 to ·5 per cent. of carbolic acid of the whole volume of blood in the body to kill bacilli and ·5 per cent. to destroy the spores. Of course this quantity present at one time in the blood would poison the patient, so that it appears carbolic acid cannot be depended on as a universal antiseptic; and until an antiseptic shall be discovered which can safely be prescribed in a sufficient quantity to act as a germicide, I fear that whooping-cough and other diseases due to bacteria will admit of the alleviation of symptoms only. I should like to add that in 1882 I took as the subject of my graduation thesis for the Dublin M.D. degree, "Whooping-cough and its Treatment by Alum," based upon a record of 200 cases which occurred in my practice in London. I showed that by the local application of alum in glycerine to the pharynx and upper part of the larynx the expiratory spasms were lessened in frequency and violence in a large percentage of recent cases. No doubt alum acts by coagulating the albumen of the mucus of the tissues, and thus shielding the parts, which are in a state of intense hyperæsthesia from irritation and consequent reflex action; also by its astringent action limiting the blood-supply, and so relieving the hyperæmia often present. The alum and glycerine is not unpleasant to take, and a little is placed on the child's tongue several times during the day and night, and if this does not seem sufficient the back of the pharynx and upper part of the larynx are carefully brushed over night and morning with the same application. This proceeding does not interfere with the treatment of complications which are generally present in cases of any duration. Everyone is aware how important it is, in rickety children especially, to stop the spasms if possible, or how quickly such patients will die of convulsions. It has occurred to me that the local application of cocaine would prove even more effectual than alum in these cases, and would not require to be so frequently applied. I should be glad to hear if this alkaloid has been tried.

I am, Sir, yours truly,

Bournemouth, Feb. 1886. A. WOODMAN-DOWDING, M.D. &c.

PROFESSORS GAUTIER AND PETERS ON ANIMAL ALKALOIDS.

(From a Correspondent.)

AT a recent *séance* of the Academy of Medicine at Paris, Professor Gautier, already well known for his researches on the subject, read a paper which bore for title "On the Alkaloids derived from the Bacterial or Physiological Destruction of Animal Tissues." This is the result of the stimulus which animal chemistry received from the discovery of ptomaines, or cadaveric alkaloids, and the subject cannot fail to be of general interest, if only from the wideness of the field of knowledge, a glimpse of which is thus afforded us in connexion with disease and morbid processes of the body. During the present reign of bacteriomania we hear a great deal of the presence of these micro-organisms in connexion with health and disease, but the subject here opened up pushes our views and reasonings still further, so that we may in the future be able to have distinct ideas as to the physiology and effect of these organisms on the tissues or pabulum where they have elected to settle; and, further, it opens up a field of research for the physiologist concerning the nutritive metabolism of each living cell.

The first part of the paper treats of the alkaloids derived from putrefaction or ptomaines, which owe their origin to the putrefactive micro-organisms, and commences with a *résumé* of the history of the subject, embodying the results obtained by Selmi and others, and then passes on to the method in which these bodies are obtained, of interest only to the chemist. The Professor concludes that these bodies are always produced in the putrefaction of animal tissues; that they are poisonous when administered to animals, and produce effects comparable to those seen when vegetable alkaloids are employed; that they are free from oxygen, and volatile or oxygenated; that they vary according to the nature of the material in which they are formed, and possibly according to the date of the putrefactive change; but one alkaloid in particular (hydrocollidine) is always found, whatever be the material used, which would seem to imply that this was the product of the bacterium possessing the most vitality in comparison with the others—the victor in the struggle for life.

The second portion of the paper deals with the leucomaines, which are alkaloids produced during the existence of the body, and which appear to be products of its ordinary metabolism. For example, five alkaloids, perfectly definite and crystallisable, have been extracted from the muscles of the higher vertebrates, having an action on the nervous centres, producing somnolence and fatigue, and some of them vomiting and purgation, but acting with less energy than the cadaveric alkaloids. These rejoice in the names of creatinine, xanthocreatinine, crusocreatinine, amphicreatine, pseudoxanthine, their names showing their similarity with the nitrogenous metabolites already known. Their existence determined, the questions arise—How are they produced? and how do we escape the evils arising from their continual reproduction and presence in the blood? The latter question is answered by saying that they are eliminated by the natural emunctories of the body, by the alimentary canal, by the kidneys, and by the skin, provided that these organs are in a condition to perform their function; but in diseases where these organs are affected the elimination of the leucomaines is incomplete, and they accumulate in the blood and tissues and give rise probably to many of the phenomena of the particular disease in question. The application of this doctrine to uræmia is so obvious that I need but to mention it, and yet its applica-

Digitized by Google

tion to many slighter ailments must quickly suggest themselves even to such a common case as that of a cold; and supposing that the doctrine be a true one we are at the same time furnished with a scientific indication for treatment—viz., to open up the emunctories and get rid of the peccant matter, which is a curious return to the doctrines of the past. The first question, Where are the leucomaines formed? the Professor answers by the remarkable statement that the higher animals are to a very large extent anaerobic—that is to say, that a portion of their tissues undergo their metabolism independently of the circumambient oxygen, and may produce this gas by the splitting up of the proteid molecule; and he quotes, in support of this statement the experiment of Pettenkofer and Voit on the respiratory changes in a dog in which there are 110 grammes of expired oxygen unaccounted for, which, according to his theory, is derived from the autonomous combustion of aliments and tissues. This is an interesting question, but rather concerns the physiologist than the practical medical man. What it behoves the latter to remember is the existence of these bodies and their method of elimination or oxidation. The former I have just mentioned, but the latter is as important. These bodies are very easily oxidised, while the supply of hæmoglobin is sufficient and good; but if from any cause this is deficient, the quantity of leucomaines and similar bodies augments, which possibly explains the nervous troubles of chlorosis, anæmia, and gestation.

The important results obtained by Prof. Gautier have been hailed with joy by the opponents of the bacterial schools of pathogeny, and already the Academy of Medicine has heard from Professor Peter the application of the discoveries of Gautier to medicine, and particularly to the views which he has for a long time taught in the amphitheatre of the Paris Faculty. In France Professor Peter is the chief antagonist of the microbian theories of disease, and he never fails to controvert and criticise their teachings. His most recent utterance was the *séance* of the Academy of Feb. 2nd, when he commenced his address with the statement that he was going to bring the support of the medicine of tradition to the medicine of the future. Briefly touching on Professor Gautier's results, which, summed up, are that the animal produces alkaloids (leucomaines) and extractive matters in the process of its nutritive changes which are endowed with toxic properties, he goes on to show how that life is but a series of deaths, how each carries with him and in him his own corpse, and by this series of deaths life is produced. Life is nothing but a partial and prolonged suicide. This being so, on what a slender thread depends the state we call health. If through defect of the emunctories or excessive production of alkaloids an accumulation takes place, the body is saturated with toxic matter, to which condition the Professor applies the term "auto-typhisation," and quotes as an example the cases where typhus arises in armies through privation and want; but when once the poison is generated in the system it can be conveyed to others, and constitutes hetero-typhisation. If this be true of typhus it is also true of typhoid, and the exact nature of the disease will vary according to the toxic material accumulated in the blood. Thus we may have true typhus, uræmic typhus (uræmia), cholæmic typhus (icterus gravis), and atheromatous typhus (ulcerative endocarditis); but the fact common to all typhic affections is the presence in the organism of an animal poison so deleterious to life that it disturbs the processes of living matter. It is infection, and the symptom common to all is τῦφος, or stupor. When the emunctories are at fault we have the accumulation of disassimilative products in the blood, which may be of the nature of alkaloids or extractive matter. The former are less toxic, and determine a hypothermia; the latter are more toxic, and produce a hyperthermia; and according to the presence of one or other of these agents the state of the temperature in uræmia can be explained, which temperature is notably subject to unaccountable variations. The Professor then briefly touched on the subject of cadaveric alkaloids, and showed how their presence may be the cause of many of the cases of poisoning by meat in a certain state of putrefaction, which conditions are accompanied by hypothermia, as in arsenic or other poisonings.

However much we may differ from Professor Gautier's views, there is no doubt that his discoveries have opened up a field of inquiry the extent of which is vast, and the application of which to processes of disease is of the easiest kind. Perhaps at present it is premature to talk of the medicine of the future; but these discoveries will doubtless have the effect of directing research to the minute details of nutritive change in connexion with this subject, and claiming some of the attention which has been directed to the research for microbes. That the microbian theory has received a severe blow is not true, as it is too well grounded in particular instances to be ever upset; but in many cases where it has failed the medical man may fall back upon the existence of leucomaines to clear his views and frame his working hypothesis, if for no other reason than his own personal satisfaction.

EDINBURGH.

(From our own Correspondent.)

SCOTTISH MEDICAL SOCIETIES.

LAST week the annual dinner of the members of the Royal Medical Society was held in Edinburgh. Dr. H. A. Thomson, the senior President, occupied the chair. Amongst the guests were the Lord Provost of Edinburgh, several of the Professors of the University, Professor Gairdner of Glasgow, and Mr. Lawson Tait of Birmingham. The chairman, in proposing the toast of the evening, "The Health of the Royal Medical Society," referred to its antiquity, this being the 150th year of its existence, and drew attention to some of the honourable names upon its roll. He specially mentioned the loss which the Society had sustained in the recent lamented death of Dr. W. B. Carpenter, F.R.S., who was senior President of the Society, and occupied the chair at its annual dinner in the centenary year of its existence, exactly fifty years ago. The Society is in a more flourishing condition than ever, its membership has steadily increased, its buildings are commodious and well arranged, and its library of 35,000 volumes is a great boon to its members. It forms an important factor in the medical training of those who are wise enough to join it in their early student days, for in its debates a facility in the public discussion and criticism of medical topics is acquired, and a familiarity with the conducting of public business is obtained—facts of great importance in the after-life of many students, as the sequel in the career of many an old member has proved. The dinner was of the usual character, enlivened with several good songs, which did credit to the musical talent of the profession, and which has always been one of its strong points in Edinburgh. It was attended by a representative gathering of present and old members, which showed that a warm interest in the Society's welfare is still maintained.

An extraordinary meeting of the Medico-Chirurgical Society was held on the 17th inst. in the hall of the Royal College of Physicians, which was specially lent for the occasion, and to which many visitors were admitted, in addition to the members of the Society. Professor T. Grainger Stewart of the chair of Practice of Physic, President of the Society, occupied the chair, and an exhaustive discussion on the subject of Abdominal Surgery occupied the whole evening. The discussion was opened by Mr. Lawson Tait, who travelled from Birmingham specially to be present on the occasion. Amongst the numerous speakers who took part in the proceedings were Professors Simpson and Annandale, Dr. John Duncan, Dr. Croom, and Dr. Byrom Bramwell.

IRELAND.

(From our own Correspondent.)

VICE-REGAL MEDICAL STAFF.

HIS Excellency the Lord-Lieutenant of Ireland has made the following appointments:—Physician-in-Ordinary: G.W. Hatchell, M.D. Surgeons-in-Ordinary: P. C. Smyly, Esq.; E. D. Mapother, Esq. Surgeon to the Household: T. Nedley, M.D. Surgeon-Oculist: A. H. Jacob, M.D. Surgeon-Dentist: D. Corbett, M.R.C.S.

ENLARGED THYROID.

At a meeting of the Surgical Section of the Academy of Medicine in Ireland, held last week, Professor Stokes exhibited an enlarged lobe of the thyroid gland, which weighed

Digitized by Google

twenty ounces. The other lobe had been removed by the same gentleman about three months since. The hæmorrhage, as is usual in these cases, was very considerable. The disease was of about two years' duration.

LUNATICS IN WORKHOUSES.

It appears from official records that on Jan. 1st, 1885, there were 3775 persons labouring under some form or other of mental disease in the various union workhouses throughout Ireland. The greater portion of these were epileptics or imbecile from birth, while aged and demented lunatics formed the remainder. As a rule, the classes thus adverted to are, as it were, indigenous to poor-houses, having been located in them in early life by the relieving officers of unions when abandoned and in a destitute state, very few of them, comparatively speaking, being transferred from district asylums. In fact, boards of guardians are for the most part strongly opposed to the detention of insane patients in workhouses, although aware that if suitable provision were made for their treatment in them, the benefits derivable from district asylums would be largely increased, their overcrowding by hopeless cases obviated, and the admission of acute and curable ones facilitated at the proper time.

SOUTH DUBLIN UNION.

The recent half-yearly report of Mr. Robinson, Local Government Board Inspector, as to the condition of this workhouse is generally of a favourable character, except as to the inadequate arrangements for the supervision of the lunatics and idiots and the insufficient accommodation provided for them. It seems that since last inspection the number of lunatics has not diminished, and both on the male and female side of the workhouse this department is so much overcrowded that many who properly belong to the insane class have to be distributed through other wards. It is expected that when the children are sent to the new schools sufficient accommodation will be found for the lunatics located in the house.

DUBLIN NATURALISTS' FIELD CLUB.

At the opening meeting of this Club, held last week, the President (Dr. E. P. Wright) stated the objects were the practical study of natural history, botany, and geology, chiefly of the province of Leinster. He reminded the members of the well-known Natural History of Birds in Ireland by Thompson, and he hoped that in time they would be able to give an equally valuable history of fishes and of the other groups of animal life. There was an equally wide field when they passed from the animal kingdom to plants, as there were whole groups of plants which were literally waiting to be collected and described. Thanks to the geological survey, the geology of the district might be said to be known, yet there was a great deal even in this branch to be done by the Club in collecting specimens of fossils, both of animals and plants, a work which did not strictly belong to the survey. Various excursions have been arranged from May to October.

HEALTH OF DUBLIN IN 1885.

The births in the Dublin registration district during last year numbered 10,144, being equal to 29 per 1000; and the deaths 10,022, or 28·4, against an average death-rate of 29·4 for the preceding ten years. A great improvement in registration was effected in 1879 by means of the burial returns then introduced in compliance with the provisions of the Public Health Act, 1878. The mortality in the Dublin district during last year was, therefore, considerably below the actual annual average for the ten years 1875-84.

By a clerical error in last week's issue it was stated that the election of a curator to the museums of the Royal College of Surgeons would take place last week. It should have been next month—viz., the 18th prox.

Dublin, Feb. 23rd.

PARIS.

(*From our own Correspondent.*)

DEATH OF DR. WILLIAM B. JOHNSTON.

THIS well-known American physician died at his residence in Paris on the 14th inst. of a chronic affection of the stomach, in the sixty-second year of his age. Dr. Johnston was a native of South America, and it was after the civil war that he came over to Europe and started as a newspaper correspondent, in which capacity he greatly distinguished himself. With his American degree he obtained permission in 1866 from the French Government to practise medicine in Paris, where he acquired great popularity and fame, not only among his countrymen, but also among the French and foreign residents of this city. He was of a handsome physique, and it is said that he bore a striking resemblance to Albert Sidney Johnston, the celebrated Southern general, who was a cousin of Dr. Johnston's father. He was officially attached to the American Legation in Paris, and always proved himself a wise counsellor on all matters coming within the scope of his profession. He rendered great service to the sick and wounded during the siege of Paris, when he was attached to an ambulance, and continued therewith to the end of the Commune, which followed the siege. In recognition of his services he was created Chevalier of the Legion of Honour, and in 1876, for further services, he was raised to the rank of Officer of the same order. He was also Officer of the Crown of Prussia. The funeral service took place at the American Church, in the midst of a large concourse of friends, the American Legation being officially represented. The remains of the lamented physician were afterwards deposited in a vaulted chamber in the church, to await removal to the United States.

PTOMAINES AND THE MICROBE THEORY.

The debate opened at the Academy of Medicine by MM. Gautier and Peter on the part played by ptomaines of disease promises to be a long one, as many members have inscribed their names to take part in it. Till now Professor Peter stands alone in his theory of auto-infection, though he cannot help conceding that some diseases are generated by microbes. The difference, however, between Professor Peter and his adversaries is that, whilst he cannot but admit the presence of microbes in certain diseases, it is yet a moot point as to whether they are the cause or the products of the disease. In any case the knowledge of bacteriology, as it is pompously termed, has thrown no light whatever on the true nature of the disease, nor has it enabled us to invalidate the teachings of the old school. The speakers who have as yet taken part in the debate seem to have forgotten all about the ptomaines, as their discussions have been confined to microbes. In an able speech, Professor Cornil endeavoured to show that the microbian theories are not really contradictory to that which is taught us by traditional medicine, but that they serve, on the contrary, to clear up many points which have till now been enveloped in obscurity. Further on, he made a sort of compromise between the old and the new doctrines by stating that the presence of micro-organisms in infectious maladies suffices to show their *rôle* in the development of disease; and without denying the influence of the soil or constitution of the individual, on which is founded the theory of the old anatomico-pathological school, it must be admitted that the modern school furnishes us with a better explanation of the specificity of different morbid states. The debate is still open, and I am afraid will remain so for some time to come, between the microbists and the non-microbists without much light being thrown upon the matter by either party, although the speakers are men of note.

THE PRIX LABORIE.

The Société de Chirurgie de Paris has awarded the Prix Laborie to Professor Lagrange, of the Faculty of Bordeaux, for his memoir on the Therapeutic Value of the Elongation of the Nerves.

ROME.

(*From our own Correspondent.*)

Solvitur acris hiems. The year has turned, and the Italian spring—or *primavera*, beautiful as its name!—has left its first imprint on meadow and mountain side. Wherever the gay world congregates, at the meet on the Campagna, on the picnic excursion to sylvan Tusculum, to the still Alban Lakes, to the headlong Anio, or with the archæological party at lonely Ostia or deserted Veii, the charm of holiday is enhanced by the exhilaration of the cloudless azure overhead, the fragrance of the wild violets under-foot, and the

Digitized by Google

gold-green haze of the woods around. Rome is looking her best, save where the city architect is trying to "improve" her! and, responsive to her attractions, visitors are trooping in with every train, till the resources of hotel and *pension* are strained to bursting, and landlord and landlady are threatened with eviction from their own rooms—not, however, without ample "compensation for disturbance." The health of the English-speaking public is good, and may till the end of the season continue so, if only they are prudent and will not cinchonise themselves, by way of precaution, into worse ailments than they would avoid.

Dr. Tommasi-Crudeli delivered before a select audience the other day a very instructive lecture on the reclamation of the Roman Campagna. Malaria, he showed, does not come from the marshes on the littoral or by the so-called winds of Africa, but is a special earth-poison, favoured in its development by the permanent humidity of the subsoil. Were the winds the importers of malaria, the breeze which prevails in Rome all summer would be pestilential, instead of which it is as health-giving as it is refreshing. That part of the city which has lately been built over or paved is thus protected from the exhaling earth-poison, and were the thorough system of drainage practised under the Antonines in the Campagna restored, that region would be as free from malaria as it was in the second century of Christ. It is no use attempting to dry up the marshes, which are of limited extent and influence; but the subsoil must be drained, saturated as it is by the percolation of water from the volcanic lakes inurned in the hills high above the sea-level. A very interesting account of the way in which the Roman engineers of the second century got rid of this subsoil water was then given, mainly from the researches of Signor Tucci, who showed that the water was collected on the hill slopes by a descending series of galleries, till in the valleys it was stored in reservoirs for legitimate uses. With the liberation of the soil from the excessive humidity one essential factor in the maturing and propagation of the malarial poison is removed.

Following up his attack on the received doctrine as to malaria, Dr. Tommasi-Crudeli has just issued a paper on the woods and their relation to that form of fever. Lancisi's theory that the low-lying belts of forest-growth between the Pomptine marshes and the Latian hills exerted a useful function in detaining and depurating the malarial poison was shown to be purely imaginary, ingeniously evolved to suit a special interest in the retention of the Cisterna thicket. Lancisi's authority was in other fields of medicine so great, so deservedly great, that his ruling in the matter has prevailed down to these days, in spite of a special commission which succeeded in showing its fallacy three years ago. The truth is that malaria resides in the soil between these forests and the city, and must be stamped out of it by removing that humidity which, when accompanied by excessive solar heat, is the main factor in its production. The thicket that Lancisi preserved has since been cut down, to the great advantage in point of health of the population in its vicinity; while had the woods high up on the mountain sides been spared (which Lancisi thought they need not be), the moisture that descends to the plain would have been reduced in quantity, and the subsoil saturation of the Campagna minimised. It is, in fact, the denuding of the Latian hills—hills, mark you, not plains—of so much of their forest-growth that makes it so difficult to revive what the engineers of the second century succeeded in doing.

"One fundamental error," says Dr. Tommasi-Crudeli, "begets an infinite series of derivatives. This idea, that trees act as a filter on the malaria, has spoiled the finest street in modern Rome. When the Via Nazionale was begun, it was planted with trees as far as the Via Quattro Fontane. But by that time a new assessor of public works appeared and argued thus: 'Foliage detains the malaria carried by the winds; in Rome malaria comes only by those winds; hence it is madness to plant those trees, which would simply act as so many condensers of malaria.' And he was as good as his word. Moreover, to prevent anyone after him from continuing the planting he had stopped at the Via Quattro Fontane, he constructed the drains of both sides of the street on the line of the plantings already begun. So all but the first few yards of the Via Nazionale is a boulevard without trees, to the increased comfort of those who have to pace it in summer, lying as it does from east to west in the greater part of its course, and therefore enfiladed by the sun, nearly all day! ..... The history of the discovery of the circulation of the blood is another striking instance in point. From Galen, who affirmed that the blood passed from the one ventricle of the heart to the other by means of foramina existing in the septum which divides the two ventricles, up to Realdo Colombo, who experimentally demonstrated that that septum was impervious, and that the blood passed from the right heart to the left heart by means of the pulmonary circulation, thirteen centuries have passed. During all these ages anatomists sought in the intra-ventricular septum for the foramina described by Galen; but they did not find them, and often confessed that they had never succeeded in seeing them—adding, however: 'They must be there, because Galen has said so.' Even the great Vesalius argued in this way up to the discovery made by Realdo Colombo. Nor, after the evident demonstrations given by Colombo, did the Galenic prejudice cease. Cesalpino himself, who passes in Italy for the discoverer of the great circulation, persisted in admitting the foramina described by Galen, when Colombo many years before had proved that no such things existed. The Lancisian prejudice will last yet awhile, but not so long as its Galenical fellow; for now the scientific world moves faster than ever, and draws along with it in its advance the lay public with more effect than formerly. Perhaps in ten or twenty years it will appear strange and unaccountable that in the year of grace 1886 I have spent so many words in combating an arbitrary assertion made in 1714, based on a physical error such as no student in our Liceo or Istituto Technico would dare to pronounce."

Dr. J. G. Van Marter is prosecuting his interesting researches in early Etruscan and Roman dentistry, and in a tomb lately disinterred near the Lago di Bolsena, belonging to the sixth century B.C., he has found a still more primitive mode of banding the teeth than in the well-known Corneto specimen, marking a distinctly earlier stage of pre-Roman dentistry. "This specimen," he says, "of early Etruscan dental work is of interest to us as the oldest yet found in Italy, and as supplying one of the missing links of the dental chain we are endeavouring to trace back to the beginning of our profession."

Rome Feb. 20th.

MEDICAL NOTES IN PARLIAMENT.

The Lunacy Laws.

IN the House of Lords, on the 19th inst., the Lord Chancellor presented two Bills for the amendment and consolidation of the Lunacy Laws. The Bills were read a first time.

The Sale of Poisons.

On the 23rd inst., the Earl of Milltown gave notice of his intention at an early date to ask Her Majesty's Government whether, considering that a Bill on the subject was read a second time in that House and referred to a Select Committee last session, it was their intention to introduce this session a Bill for regulating the sale of poisons.

The Rating of Hospitals.

In the House of Commons, on the 22nd inst., Mr. Baggallay gave notice of his intention on an early day to call attention to the unsatisfactory state of the law with regard to the rating of hospitals and other public charities in the metropolis.

The Purification of Rivers.

Leave was given to Mr. Hastings to bring in a Bill for the purification of rivers, which Bill was afterwards read a first time.

The Public Health Act.

On the 23rd inst., Mr. Chamberlain, in reply to Mr. J. E. Johnson-Ferguson, stated that his attention had been called to a prosecution by the Atherton Local Board before the Leigh (Lancashire) bench of magistrates under the Public Health Act, 1875, for the removal in a public conveyance of the dead body of a child who had died from an infectious disorder without previously notifying to the owner or driver that it had died from such a disorder; and he had no doubt whatever that the decision of the magistrates was right, and that the word "person" in the Act did not include a dead body, and that a dead body was not a thing *ejusdem generis* with bedding, clothing, or rags. Under these circumstances it was evident that there had been an omission in the Act, and if the Act came up for amendment that point would be noticed.

Obituary.

GAVIN MILROY, M.D., F.R.C.P.

DR. GAVIN MILROY was born in Edinburgh, where his father was a silversmith. He received his general education in the High School, and studied medicine in the University of his native city. A fellow-student who survives him states that he was distinguished by his indefatigable industry and intelligence, as well as by the urbanity of his manners, and that he was also known among his fellow-students as "little Milroy," a term of endearment used by them. It may be said that those characteristics of his youth lasted throughout his long career. He graduated M.D. in 1828. On the completion of his student course, he became one of the founders and active members of the Hunterian Society of Edinburgh, and in his maturity he was similarly related to the Epidemiological Society of London, founded under the late Dr. Babington in 1850. He was secretary of that Society from 1862 to 1864, and its president from 1864 to 1866. Its Transactions contain several valuable contributions by him. He was elected F.R.C.P. in 1853. It appears that he never practised medicine on his own account, but from his early manhood made choice of its literary path. Previously to doing so he availed himself of an appointment as medical officer in the Government Packet Service to the West Indies and the Mediterranean, and it is presumable that in the latter, on returning from the Ionian Islands to Malta, he must have undergone quarantine at the latter place, where the practice was rigidly enforced on all arrivals from the Levant. Although his stay in that service may not have been of long duration, he retained a predilection for the navy, which led him at a later period to contribute a paper entitled "The Health of the Navy considered." Being a young physician of medical erudition, he was retained, together with Mr. Chatto (now the esteemed librarian of the Royal College of Surgeons), on the staff of the then influential periodical, the *Medico-Chirurgical Review*, and after the death of Dr. Johnson, its proprietor, they, conjointly with the late Mr. Grainger, undertook the management of it until fused with the *British and Foreign Medico-Chirurgical Review*. In that position he made his first mark as a public writer suitable to the occasion, and competent to deal with the great medical question of special interest to Englishmen, as the chief merchant-adventurers and ocean-carriers in the world. It fell to him to review, in 1846, a report by Dr. Prus on "Plague and Quarantine" to the Academy of Medicine of Paris, the argument of which was against quarantine. He subsequently translated this report in order to place the facts and reasonings it contained within the reach of the English reader in a cheap and accessible form. His translation is entitled "Quarantine and the Plague, being a Summary of the Report on these subjects recently addressed to the Royal Academy of Medicine in Paris, with Introductory Observations, Extracts from Parliamentary Correspondence, and Notes." Dr. Milroy then came prominently into view as a publicist through the credit gained by him in performing this task, which was done with so much ability that he stood forth as an authority on all questions of epidemiology, at that time rising in public as well as in professional estimation as an important branch of medical and social science. His views were deemed the best adapted to enlarge commercial enterprise by abolition, or by great mitigation, of its chief restraint, quarantine, as well as to benefit the public health of the nation by trusting to sanitary measures alone to guard against the ravages of cholera and other foreign pestilences. Having gained the good opinion of statesmen, he obtained employment in the public service as a superintendent medical inspector of the General Board of Health, in 1849-50 and 1853-55; and when, in 1850, cholera first showed itself in our West Indies, he was sent by the Colonial Office to Jamaica to "inspect and report on the sanitary conditions of that island," which he did with promptitude to the satisfaction of the Government. He afterwards presented to the authorities the details of the origin and track of its great cholera epidemic, and of the social conditions of the natives, with recommendations of sanitary measures. In the spring of 1855 the War Office sent to the Crimea a Sanitary Commission, "with powers of entry into every hospital, infirmary, or receptacle of whatever kind for the sick and wounded, whether ashore or afloat," reporting the results of their inspection to the superior officers of the service concerned, and further "to see to the keeping of the harbour of Balaclava in a clean condition." A vacancy occurring in that Commission, Dr. Milroy was sent out to fill it, and he joined it in July. He proved himself an able coadjutor with Dr. Sutherland in the inspection of camps, hospitals ashore and afloat, of wharves and roads, wherever operations were being actively carried on from Scutari to Kertch. The recommendations of the Commission were in the right direction, and were such as would have been carried out by the Army Medical Department if it had been possessed of similar powers. There can be no doubt that their adoption contributed to the subsequent healthiness of the army, but in estimating their influence in this respect, it must be borne in mind that very marked improvement in the health of the army had manifested itself with the first advent of spring, before the presence of the Commission on the scene could have operated. The excessive strain imposed on the troops by the military exigencies and the want of adequate food and clothing during the winter had been relieved by a full supply of both, and the spirit of the troops had been aroused by the prospect of an early reopening of the batteries. When that took place the whole aspect of affairs was changed, and a good state of health was established in an army that had landed with epidemic cholera in its train, had fought and conquered with that dire foe in its ranks, and then had passed a hard-worked and half-starved winter in the trenches outside a beleagured city. After the capture another winter was passed in comfort and health; and when, in the following summer, the terms of peace were on the point of being settled, the Sanitary Commission was recalled. The report of its transactions was drawn up by Dr. Sutherland and Dr. Milroy. In 1858 the National Association for the Promotion of Social Science appointed a committee to inquire into the practice and results of quarantine in all parts of the world. The late Earl of Shaftesbury was president, and Dr. Milroy was honorary secretary of that committee. In April, 1859, a series of queries prepared by it was forwarded to the Foreign and Colonial Secretaries of State by Lord Shaftesbury for circulation among the consuls and colonial authorities. The replies were placed at the disposal of the committee, and the laborious task of examining, arranging, and digesting the information contained in them devolved on Dr. Milroy as secretary, and the results were communicated to the Board of Trade. These were published in Parliamentary Papers. The first, ordered to be printed Aug. 25th, 1860 (No. 568), was an "Abstract of Regulations in Force in Foreign Countries respecting Quarantine"; the second, ordered to be printed Aug. 21st, 1860 (No. 568-1), "Abstracts of Information Concerning the Laws of Quarantine"; and the third, ordered to be printed Aug. 6th, 1861 (No. 544), "Papers relating to Quarantine." These papers contain information not only regarding the laws and practice of quarantine, but also on the appearance and prevalence of the diseases for which it is imposed in various parts of the world. It is unnecessary to state that in them the views of the Epidemiological Society of London are fully displayed. He was a much-prized contributor to the columns of THE LANCET.

Eventually a life pension of £100 a year was granted to Dr. Milroy in recognition of his various services. From this period he devoted himself in retirement to his favourite studies, and to literature. By his influence with the Royal College of Physicians a committee was appointed to investigate the nature and imputed contagiousness of leprosy and yaws; and he was the author of the report of that committee presented to Parliament in 1873. Always abstemious and economical, he found himself in a position to present to the College of Physicians the sum of £2000 for the endowment of a Lectureship on Public Health and on Sanitation. Dr. Milroy lived to the age of eighty-one, retaining to the last his mental faculties, as well as an active interest in social matters of a beneficial tendency. He died at Richmond, in Surrey, on Jan. 11th, and was interred on the 15th in Kensal-green Cemetery, beside the remains of his beloved wife, whom he had survived about three years. He was a successful public benefactor, remarkable for his unostentatious and deferential characteristics, by which he secured the confidence and esteem of those associated with him. W. R. E. S.

PROFESSOR M. R. LEVI.

THE republic of medicine has lost an able and energetic citizen in Dr. M. R. Levi, clinical consultant in the Children's Hospital of Florence. He was but forty-five years of age, and fell a victim to one of these rapid pneumonias which, far more than fever, contribute to swell the mortality in Italy. Up to the 8th inst. he was at his post, lecturing with characteristic clearness and effect, and within a week he was "gathered to the majority."

His professional studies were commenced and carried on in the Medical School of Venice, where he had for his teacher the distinguished Professor Nahmias, whose researches in cholera have served so signally to enlighten Italian physicians and municipal bodies as to its origin and prevention. After graduation he was appointed Clinical Lecturer on the Diseases of Children in the University of Padua, in which capacity he acquired a reputation throughout the peninsula as an acute and successful consultant in that class of disorders. Having settled in practice at Venice, he did admirable work in the Hospital for Rachitic Children on the Lido; and at the International Medical Congress held in Florence in 1866 he was specially applauded for his exertions in behalf of the poor population of the lagunes, which culminated in the institution of the Ospizi Marini. He was an indefatigable coadjutor on the *Sperimentale*, the well-known organ of the Florentine Medical School, and his valuable contributions to its pages secured him in 1882 the appointment to the Clinical Professorship of the Diseases of Children in Florence, a subject he had made peculiarly his own. Year by year his clinic gained in professional repute, his success in tracheotomy, in croup especially, being attested by the statistics he published in his reports. For the last eighteen months his activity was certainly too intense, as manifested not only in his clinical and general practice, but in his scientific papers read before the various societies of Florence. At the Medical Congress held last autumn in Perugia he took a prominent part, and his friends thought they discerned in him the first foreshadowings of that physical waste that accelerated his demise. Their prevision, conveyed to him in kindly warning and remonstrance, had but little effect, for his participation in the transactions of the Florentine Medico-Physical Society and the Institute of Hygiene was more eager and extended than ever, until the fatal illness that carried him to the rear.

His loss will be keenly felt, not only by his colleagues and compatriots, but by the numerous English physicians who, first in Venice and latterly in Florence, have profited by his sound science and courteous hospitality.

ALFRED C. POST, M.D., LL.D.

DR. ALFRED POST of New York, whose death has recently occurred, was born in 1805, and, after receiving professional instruction at the New York College of Physicians and Surgeons, graduated in 1827. He afterwards studied at Paris, Berlin, and Edinburgh. In 1829 he commenced the active practice of his profession, and continued it until the week before his death. As early as 1836 Dr. Post was appointed one of the attending surgeons of the New York Hospital, and more recently was connected with the medical staffs of St. Luke's and the Presbyterian Hospitals. He was one of the founders of the medical department of the University of the city of New York, taking the chair of Surgery and Pathological Anatomy, and at the time of his death was President of the Medical Faculty and Emeritus Professor of Clinical Surgery in that institution. He was a member of the New York Academy of Medicine, serving it as vice-president; of the Pathological Society, once its president; and of many other American and foreign societies. Dr. Post was an impressive, terse, and explicit lecturer; a bold, steady, and self-reliant operator; and a lucid, logical, and classical writer. In actual practice for fifty-seven years, New York has by his death lost her oldest and one of her best known medical men.

FREDERICK ROW, M.D.

WE regret to announce the death of Dr. F. Row of Devonport, which occurred on the 20th inst. The deceased, who was born in 1811, received his early education at Devonport Grammar School, and studied for the medical profession in London, Paris, Edinburgh, and Dublin. In 1834 he became a Licentiate of the Royal College of Surgeons of Edinburgh and of the Apothecaries' Society of London, and in 1835 obtained the degree of M.D. at the Edinburgh University, afterwards commencing practice at Torpoint. Dr. Row formerly held a commission as surgeon to the 2nd Devon Rifle Volunteers, which post he resigned on being appointed a Justice of the Peace for the borough of Devonport. For many years he was a senior surgeon to the Royal Albert Hospital, and on resigning this position he was appointed consulting physician to the institution, an office which he held until his death. He took a great interest in everthing that concerned the welfare of the town in which he resided, and it was mainly due to his energy that the Devonport Free Library was first brought into existence. In 1870, at a meeting of the Social Science Congress, Dr. Row read a paper, which was afterwards published, on Prison Discipline. He was a man of genial temper, and his decease will be long regretted by a large circle of friends.

SIGISMUND SUTRO, M.D., F.R.C.P.

BY the death on the 19th inst., from apoplexy, of Dr. Sutro the German community of London have lost one of their best known and most highly esteemed medical advisers. The deceased, who was a native of Bavaria, was born in 1815, and studied at Munich and Heidelberg, taking the degree of Doctor of Medicine at the former university in 1840. In 1859 he became a Member of the Royal College of Physicians of London, and in 1873 a Fellow of that body. For many years Dr. Sutro acted as senior physician to the German Hospital, and upon resigning that office he was appointed consulting physician. He was a member of several of the Medical Societies, and the author of several works, the majority of which relate to the German mineral waters and spas and to the progress of German medical science.

Medical News.

BRITISH MEDICAL SERVICE.—The following is the list of candidates who were successful for appointments as Surgeons in the Medical Staff of H.M. Army at the competitive examination in London on Feb. 8th and following days:

	Marks.		Marks.
Fayrer, J.	3685	Garner, C.	2325
Davidson, J. S.	3030	Marks, G. F. H.	2310
Will, J.	3025	Scott, G.	2310
Fallon, J.	2980	Greig, D. M.	2300
Moir, J.	2965	Donaldson, J.	2295
Salvage, J. V.	2840	Holyoake, R.	2275
Bostock, R. A.	2835	Edye, J. S.	2270
Aldridge, A. R.	2830	Russell, J. J.	2260
Walker, C. P.	2770	Bate, L. A. F.	2230
Fowler, J. F. S.	2725	Allport, C. W.	2215
Macdonald, C. J.	2695	Barefoot, G. H.	2205
Burrows, J. R.	2650	O'Callaghan, D. M.	2180
Tatham, C. J. W.	2630	Windle, R. J.	2175
Austin, H. W.	2620	Wright, R. W.	2150
Clarkson, T. H. F.	2610	Knaggs, H. T.	2140
Kelly, R. E.	2600	Newland, T. R.	2125
Hone, H. St. G. S.	2580	Foott, R. E.	2110
Donegan, J. F.	2550	Traver-Smith, V. E.	2100
Keatly, J.	2550	Mathias, H. B.	2095
Saunders, D. M.	2550	Hosie, A.	2080
Cattell, R. J. C.	2520	Buist, R. A.	2060
Beat, G.	2490	Watson, J. J. C.	2060
Cumming, H. A.	2450	Whaite, F. D.	2060
Deacon, J. G.	2450	Smyth, N.	2040
Marder, E. S.	2400	Trotter, W. J.	2030
Hennessy, D.	2395	Dowman, W.	2020
Whilty, M. J.	2390	Kiddle, W.	2020
Eckersley, E.	2380	Browning, T.	2000
Bailey, W. F.	2360	Cronin, C. S.	1980
Hall, R. J. D.	2330	Le Quesne, F. S.	1940

INDIAN MEDICAL SERVICE.—The following candidates for this Service were successful at the competitive examination held at Burlington House on Feb. 8th:—

	Marks.		Marks.
Pisani, L. J.	3265	Dawson, A. W.	2870
Thorold, W. G.	3260	Hudson, E.	2830
Hehir, P.	3200	Fooks, H.	2810
Basu, B. K.	3105	Robinson, W. H. B.	2800
Edwards, W. R.	3015	Sheppard, H. A.	2800
Daly, J. T.	2955	Deare, A. C.	2790
Bell, G. J. H.	2950	Evans, J. F.	2745
Sinhar, N. P.	2920	Macteggart, C.	2710

Thirty-seven candidates competed for sixteen appointments; all were reported qualified.

NAVAL MEDICAL SERVICE.—At the competition for commissions in the Medical Service of the Royal Navy, held on Feb. 8th and following days in the Hall of the University of London, Burlington-gardens, the undermentioned gentlemen were the successful candidates:—

	Marks.		Marks.
Stericker, F. W.	3050	Apthorp, E.	2455
Bate, J. F....	2995	Hadden, H. J.	2380
Pryn, W. W.	2760	McDonnell, J. J.	2360
Kennedy, G. E.	2670	Webb, J. E.	2360
Barry, J.	2600	Thorpe, V. G.	2350
Pickthorn, A. J.	2535	Atock, M. H.	2345
Spiller, E. A.	2490	Meaden, E. H.	2320
Andrews, J.	2465	Dawe, J. H.	2310

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentlemen have recently been admitted Licentiates of the College:—

Pierce J. J. O'Connor, Joseph A. Scully, Patrick J. Sheridan, James G. Westlake, and Mándvivala Fakirji Kabasji.

The following has been admitted a Fellow:—

James McCloghry, Surgeon, A.M.D.

THE annual general meeting of the National Health Society was held on the 23rd inst.

DIALECTICAL SOCIETY.—At Anderton's Hotel on Wednesday next, commencing at 8 P.M., there will be a debate on the Contagious Diseases Act.

BEQUESTS.—Sir William Kellett, Bart., has left £50 to the City of Dublin Hospital, and a similar amount to the Hospital for Incurables, Donnybrook.

THE Secretary of State for War has appointed Mr. W. L. Chubb to be Visiting Surgeon for Shorncliffe, under the Contagious Diseases Acts, 1866 to 1869.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At a meeting of this Society on the 19th inst., a conjoint paper on the Protection of Milk from Contamination was read by Mr. A. Wynter Blyth and Mr. Alfred Spencer.

MEDICAL MAGISTRATE.—The Lord Chancellor has appointed Augustus Rowland Ticehurst, M.R.C.S. &c., of Silchester House, St. Leonards-on-Sea, a magistrate for the borough of Hastings.

THE St. Petersburg financiers have decided to erect a hospital of fifty beds as a memorial of the late Emperor Alexander II. The Town Council has presented a piece of ground in the Ekaterinhoff Park for the purpose.

AT the inauguration of the South-Western Sanitary Inspection Association, which took place at Putney on the 20th inst., Mr. Edwin Chadwick, C.B., delivered an address on the "Sanitation of London and the Suburbs."

YOUNG MEN'S CHRISTIAN ASSOCIATION.—Sir Joseph Fayrer, K.C.S.I., will deliver a lecture at Exeter Hall on Tuesday, March 2nd, on the subject of the "Natural History, Habits, and Diffusion of Cholera, and what may be done to prevent or mitigate it."

THE annual general meeting of the subscribers and friends of the East London Nursing Society was held on the 23rd inst. The object of this Society is to nurse the sick poor in their own homes by means of trained nurses.

ST. PANCRAS WORKHOUSE.—The guardians of the poor of the parish of St. Pancras have unanimously resolved to appoint an assistant to Dr. Dunlop, the medical officer of the workhouse of the parish. This workhouse now contains over 2000 inmates, over 1200 of whom are under medical care.

VACCINATION GRANTS.—The following gentlemen have received the Government grant for efficient vaccination: Mr. Charles Sage Ticehurst, of the No. 2 District of the Petersfield Union (second time); Mr. F. G. Stewart, of the No. 2 District of the Bodmin Union; and Dr. Gervis, Ashburton district (third time).

COUNTESS OF DUFFERIN'S FUND.—Her Majesty having signified to the Countess of Dufferin her intention of presenting medals to the most distinguished female licentiates in the medical schools of India, the central committee purpose awarding them in the following manner:—A gold medal will be offered for annual competition in each of the four Indian Universities—Bengal, Bombay, Madras and Lahore; students at the Agra medical school being allowed to compete at Lahore. The Viceroy has also placed five silver medals at the disposal of the National Association.

AT the annual meeting of the governors of the Newcastle-on-Tyne Sick Children's Hospital, on the 24th inst., Mr. Fleming intimated that, as the hospital was not in a suitable locality and was too small, he had decided to build a new one, with over double the accommodation and in a more salubrious locality, and to furnish it throughout.

WIGAN MEDICAL SOCIETY.—The annual meeting of this Society was held on Feb. 18th, 1886, and the following office-bearers and committee were elected for the ensuing year:—President: W. Berry, Esq., J.P., M.R.C.S. Vice-President: J. B. Stuart, Esq., F.R.C.S.Ed. Hon. Secretary and Treasurer: R. P. White, Esq., M.B.Ed., M.R.C.S. Committee: J. White, Esq., J.P., M.R.C.S.; W. C. Barnish, Esq., M.R.C.P.Lond.; N. Hannah, Esq., L.R.C.P.Ed.

ROYAL NORTHERN SEA-BATHING INFIRMARY, SCARBOROUGH.—The annual meeting of the supporters of this institution was held on the 20th inst. The report stated that the infirmary was open from May 1st to Dec. 12th, during which time 562 patients were admitted, being 39 more than in 1884, and the largest number that has been received in the institution in any one year since it was established. The income had amounted to £1578 and the expenditure to £1498.

KING'S COLLEGE HOSPITAL.—The report read at the annual court of the corporation of this hospital on the 24th inst. showed that during the past year the number of cases under treatment in the hospital had been 2205, and the number of attendances in the out-patient department 28,653. The deficit for the year amounted to £5032. On the 12th prox. a public meeting is to be held at the Mansion House to consider the question of the financial position of the institution.

THE HELEN PRIDEAUX MEMORIAL FUND.—At a meeting of the subscribers to this fund, presided over by Sir William Gull, on the 20th inst., it was resolved that the income derived from the sum now raised be given as a prize every second or third year to a woman who has already completed the ordinary course of medical education, to help her on to a further stage, and that it be called the "Helen Prideaux Prize." It was also resolved that the Dowager Lady Stanley of Alderley, Mrs. Garrett Anderson, and Mrs. Stanley Boyd be made trustees of the fund, and that the duty of awarding the prize be left absolutely in their hands.

THE SEAMEN'S HOSPITAL.—The fifty-sixth annual meeting in connexion with this hospital was held on the 24th inst., when the report showed that during the year 1551 patients had been under treatment, against 1751 in 1884; and the number of out-patients relieved was 5874, against 5329. The building has been rearranged, and now accommodates 258 patients, instead of 243 as formerly; the system of drainage has also been remodelled. Since the foundation of the institution 133,397 patients have been admitted, and of these 106,023 were discharged as cured and 7515 died.

HYDROPHOBIA IN PARIS.—There were, according to Dr. Dujardin-Beaumetz, 19 deaths from hydrophobia in Paris last year—a number higher than in previous years; and yet the number of stray dogs destroyed was also higher—viz., 5060. Of these 19 persons, 15 were males and 4 females. The time of incubation varied from 19 months (in the case of a young man of twenty-six) to 29 days (a child of eleven.) In only one case was the time of the bite unknown. Excluding that, and the exceptional case of 19 months, an average of about 2 months is arrived at for the time of incubation. As to duration of the disease, the extreme limits were 1 day and 8 days; average 3½ days. In no case were the lower limbs bitten.

THE DALRYMPLE HOME FOR INEBRIATES.—At a meeting of the British Medical Temperance Association, held on Feb. 24th, Dr. B. W. Richardson in the chair, Dr. Norman Kerr, consulting physician to this Home, gave a *résumé* of the results of his second year's experience. Seventy-eight cases had been admitted, thirty-seven under the Act and forty-one as private patients; of these, seven were doctors and five lawyers. There were also merchants, men of fortune, stockbrokers, farmers, clerks, military officers, &c. Of the sixty discharged, and whose after-history was known, one-half had been so much improved as to be able to fulfil the duties of their station in life. The success of the Home had exceeded Dr. Kerr's expectations.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ARMSTRONG, BENJAMIN, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Hainton District of the Louth Union.

BAKEWELL, R. H., M.D., has been appointed Visiting Physician to the Christchurch Hospital, New Zealand.

BRAUND, JAMES M., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Marhamchurch District of the Stratton Union.

CAPE, JOSEPH T., M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer for the Halwell District of the Totnes Union.

COLTART, W. WILSON, L.R.C.P.Lond., M.R.C.S., has been reappointed Medical Officer for the Headley District of the Epsom Union.

COX, WILLIAM A., M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer for the Banstead District of the Epsom Union.

DODSON, ARTHUR E., L.R.C.P., M.R.C.S., has been appointed Medical Officer to the Wandsworth and Clapham Union Workhouse.

HAINS, L. J. C., L.R.C.P.Ed., L.R.C.S., has been appointed Medical Officer for the Harberton District of the Totnes Union, vice Hains, resigned.

JOHNSON, H. SANDFORD, L.F.P.S.Glas., L.K.Q.C.P.I., has been re-appointed Medical Officer for the South Brent District of the Totnes Union.

OSBURNE, C. A. P., L.R.C.P.Ed., L.R.C.S., has been appointed Medical Officer for the Fourth District of the Church Stretton Union.

PIZEY, G. P., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Ninth District of the Bedminster Union.

RANDLE, J. MAYNE, L.R.C.P.Lond., M.R.C.S., has been reappointed Medical Officer for the Ugborough District of the Totnes Union.

UBSDELL, HENRY, M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer for the Staverton and Rattery District of the Totnes Union.

WELLS, Sir T. SPENCER, Bart., F.R.C.S., &c., has been appointed Consulting Surgeon to the Hampstead Home Hospital and Nursing Institute, vice John Gay, F.R.C.S., deceased.

WILSON, J. E. C., L.R.C.P.Ed., L.R.C.S., has been appointed Medical Officer for the Clowance and St. John's District of the Parish of Stoke Damerel Union.

WILSON, S. M. W., M.R.C.S., L.S.A.Lond., has been appointed Consulting Surgeon to the West Norfolk and Lynn Hospital, vice Lowe, resigned.

Births, Marriages, and Deaths.

BIRTHS.

APPLEBE.—On the 22nd inst., at Pemberton House, Hay, Breconshire, the wife of E. A. Applebe, L.R.C.P., of a son.

BURN.—On the 21st inst., at Ecclesbourne, Bedford-hill, Balham, the wife of W. Barnet Burn, M.D.Lond., of a son.

DAVY.—On the 12th inst., at Woodland-road, Upper Norwood, the wife of Surgeon-Major F. Arthur Davy, M.D., Medical Staff, of a daughter.

JACKSON.—On the 17th inst., at 64, Cambridge-terrace, Hyde-park, W., the wife of Herbert F. Vaughan Jackson, M.R.C.S.Eng., L.R.C.P.Lond., of a daughter.

LAMB.—On the 21st inst., at Kensington-park-gardens, the wife of W. H. Lamb., M.B.Lond., of a daughter.

LEACROFT.—On the 21st inst., at Hartington-street, Derby, the wife of J. W. Leacroft, M.B.Aber., L.S.A.Lond., of a daughter (stillborn).

MATCHAM.—On the 11th inst., at Gladstone-street, Southwark, the wife of Alfred Matcham, M.R.C.S., L.R.C.P.Ed., of a son.

SWEETING.—On the 23rd inst., at 40, Charleville-road, West Kensington, the wife of R. D. R. Sweeting, M.R.C.S.Eng., and S.Sc.Cert.Cantab., of a daughter.

MARRIAGES.

DAUNT—GODDEN.—On the 20th inst., at the Parish Church, Croydon, George Daunt, L.R.C.P.Ed., L.R.C.S.Ed., fourth son of Nicholas Daunt, co. Cork, to Lilian Alice A., fourth daughter of Wm. Godden, of Hollington, South Norwood-park, Surrey.

LEY—NORRIS.—On the 17th inst., at Holy Trinity Church, Birchfield, by the Rev. Pelham Maitland, M.A., Henry James Ley, M.B.Edin., youngest son of the late Richard Ley, M.R.C.S., of Ringmore, Teignmouth, to Nellie Pratt, second daughter of Richard Norris, M.D., of Birchfield. No cards.

LYONS—CRUX.—On the 18th inst., at St. Luke's, Oseney-crescent, Surgeon-Major Frederick Lyons, Medical Staff, to Emily Pickering, only surviving daughter of the late Frederick Crux.

PEARSE—HEYLAND.—On the 27th ult., at St. George's, Hanover-square, Francis J. Pearse, younger son of Dr. Pearse, of St. George's-square, S.W., to Agnes, youngest daughter of the late Captain Langford Heyland, formerly 17th Lancers.

DEATHS.

HATCHETT.—On October 21st, at Blantyre, Lake Nyassa, East Africa, of fever, Frederick William Hatchett, L.S.A.Lond., youngest son of the late John Charles Hatchett, formerly of Newtown Lodge, Hungerford, Berks, and Preswylfa, Neath, aged 26.

HOUNSELL.—On the 22nd inst., at Woodlands, Torquay, Henry Strangway Hounsell, M.D.

LIVESEY.—On the 1st inst., of exhaustion, following rheumatic fever, Ernest Livesey, M.R.C.S.

MASSY.—On the 17th inst., at Powis-road, Brighton, Richard Tuthill Massy, M.D.

ORD.—On the 18th inst., at Paragon-place, Brixton-hill, S.W., George Ord, F.R.C.S., aged 84.

SUTRO.—On the 19th inst., at Finsbury-square, Sigismund Sutro, M.D., F.R.C.P., in his 71st year.

WORDSWORTH.—On the 22nd inst., at his residence, Harley-street, W., John Cawood Wordsworth, F.R.C.S., late Senior Surgeon to the Royal London Ophthalmic Hospital, Moorfields, second son of the Rev. Wm. Wordsworth, of Monk Bretton, Yorkshire, in his 63rd year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

EXAMINATION OF CANDIDATES FOR HER MAJESTY'S ARMY, INDIAN, AND NAVAL MEDICAL SERVICES.

Medicine.

Tuesday, February 9th, 1886, from 10 A.M to 1 P.M.

1. A case for Critical Analysis and Commentary:—"A young man whose breath was not short generally, and who had always been used to active exercise, began to observe that on running long or fast the breathing would become noisy like that of a 'roaring' horse. For twelve months he had been in the habit of riding fast for several hours daily, believing he would thereby improve his breathing powers. On one occasion, having put his horse to full speed, he brought on a severe fit of palpitation, and his breath had been shorter ever since. During the past three months he had an occasional dry cough, and frequently a pain in the centre of the chest. He nevertheless persevered with his active exercise, but now chiefly walking; and one day when making some exertion with his arms in fencing, he was suddenly seized with extreme oppression of breathing, spasm, and panting. On recovering from this condition there followed frequent cough and shortness of breath, especially on any increased exertion, with occasional attacks of increased difficulty of breathing in the morning. He had lost strength and colour. Pulse 80 (weak and unsteady). On careful examination of the chest, the breath sounds were found distinct in every part, especially inspiration, which was louder and harsher than usual. No prolonged expiration, wheeze, or crepitus. Above the left scapula the breath and voice sounds were tubular. The heart sounds were very weak; and a slight venous murmur was heard in the neck. The movements of the chest, its shape, and percussion sounds were normal. Night attacks of difficult breathing continued, described as being in the throat and of a choking character. About a week after the first examination of the patient, and when the more severe symptoms had existed three months, there occurred a bad attack of breathing in the morning. For two days before that he had walked continuously for three hours and a half (endeavouring to improve his breath), and was so much exhausted that he could eat no food. Next morning, on awaking, he had the 'bad attack of breathing,' which almost suffocated him. He had felt exhausted and weak ever since, and could take very little solid food. On listening to the chest, the inspiratory sound was heard loud in every part, and somewhat harsh in tone, especially at the upper parts of the chest; but no laryngeal stridor or hoarseness such as is present in laryngitis. The tubular sounds were still distinct above and within the left shoulder blade; but abnormal pulsation could neither be heard nor felt in any part. Inability to take solid food added to the increasing weakness of the patient; and two days later he had fallen on the floor unconscious after a fit of difficult breathing with laryngeal spasm. On recovering consciousness, he remained free from cough and spasm; the pulse was steady and breathing tranquil, but accompanied with a laryngeal sound; and laryngeal spasms continuing to recur at shorter intervals tracheotomy was had recourse to; but the breathing was not relieved thereby, and death followed one hour and twenty minutes after the operation." State your views regarding the probable origin, the progress and development of the symptoms and physical signs in this case, with their mutual relationship, if any; lastly, give some explanation as to why tracheotomy failed to give relief.

2. A case for Critical Analysis and Commentary:—"Elizabeth R——, aged forty, was admitted into St. Thomas's Hospital, September 11th, 1876; married, with five living children, ages varying from five to sixteen years; three miscariages, first twelve months after marriage—a three months' fœtus; the last four months before admission. General ichthyosis, but no history of syphilis. Habits not very temperate; ordered a pint and a half of beer daily, besides some spirits; patient had suffered from morning sickness independently of pregnancies. Nine months before admission vomiting became more frequent; had great pain across the stomach and in the back, with persistent diarrhœa, cough, loss of appetite and flesh. With these symptoms the abdomen began to swell. She remained in hospital until October 25th, and during this time her condition was as follows:—Emaciated; venous stigmata on cheeks; jaundiced tint of conjunctivæ; abdomen enlarged, measuring thirty-nine inches at umbilicus; liver much enlarged, measuring nine inches in right mammary line; and lower margin felt hard, sharp, and even below umbilicus; surface smooth; moderate ascites; frequent vomiting and constant diarrhœa; no sign of cardiac disease, but slight dulness and tubular breathing at apex of right lung; temperature at night usually 101° F.; occasional attacks of profuse epistaxis; no albuminuria. On leaving hospital she seemed better; no ascites, and no diarrhœa. One month after leaving hospital the abdomen began to swell again. Towards the end of January, 1877, diarrhœa returned; and on Feb. 29th, the patient was readmitted into hospital, her condition being as follows:—Very weak and emaciated; girth of abdomen thirty-seven inches and a half; liver still very large, measuring in the right mammary line nine inches and a half, and extending from nipple to below umbilicus; surface hard and slightly tender, generally smooth, but a large projecting mass felt in epigastrium; spleen enlarged; moderate ascites; constant diarrhœa (eight to ten watery motions, without pain, daily); no vomiting;

Digitized by Google

tongue unnaturally red and clean; appetite bad. Skin sallow and anæmic; no decided jaundice, but urine contained bile-pigment and one-eighth albumen. Almost constant epistaxis and greater fetor of breath; pulse 120; heart healthy. She became daily worse, and on March 2nd she vomited about a pint of dark blood; the ascites diminished slightly, but diarrhœa and epistaxis persisted, and on March 15th she died from exhaustion." Discuss the pathology and probable morbid anatomy of this case, and in doing so state, first, in inches, the ordinary extent of hepatic dulness in the right mammary line, and define the anatomical limits of the upper and lower margins of the liver in health in the same line; second, explain in detail the origin and development of the symptoms, physical signs, and your conclusions as to diagnosis; third, describe how you would treat such a case; and, lastly, in your account of what you expect to find (post mortem), give some explanation as to the possible or probable nature of the projecting mass felt during life in the epigastrium.

3. Describe the characteristic lesions in a typical case of enteric (typhoid) fever when death has taken place towards the end of the second week, and give an account of the stages through which the lesions may pass.

4. Finding a patient comatose and stertorous of whom you can obtain no history, you are required to diagnose as between narcotic and alcoholic poisoning, uræmia, epilepsy, or external injury on the one hand, and from apoplexy on the other. State the main points on which you would rely in distinguishing between these conditions.

5. What do you understand by "cardiac tonics"? Name the medicines used as such. Describe their action on the heart in full and in poisonous doses (defining such doses); and mention the kind of cases and the conditions of the heart in which cardiac tonics may be of use; and also the risks attending the administration of them.

Chemistry.

Tuesday, February 9th, 1886, from 2 P.M. to 4 P.M.

1. What is ammonia? Give its symbol. Describe some process by which it may be prepared.

2. Describe the action of chlorine as a bleaching and a disinfectant agent.

3. By what common properties are chlorine, bromine, iodine, and fluorine distinguished from the other elements?

4. To what extent may carbonic acid accumulate in the air of a room beyond the normal amount in the atmosphere without rendering the air of the room unfit for human respiration?

Zoology.

Tuesday, February 9th, 1886, from 4 P.M. to 6 P.M. (Not more than one question in each subject to be answered.)

1. Refer to its subkingdom, class and order the red coral of commerce.

2. Contrast the respiratory system of the whelk (*buccinum*) with that of the snail (*helix*).

3. What are the most important modifications presented by the sternum in birds? Give examples.

Botany.

4. Describe a typical vegetable cell and cite an example of a plant whose grade of differentiation never passes beyond that of a simple cell.

5. What is the most characteristic action of the leaves of plants on the atmosphere? How is this modified by the presence or absence of sunlight.

6. Point out the difference between a syncarpous and an apocarpous ovary. Give an example of each from genera contained in the Pharmacopœia.

Physics.

7. What is electrical induction? Describe the changes in which this phenomenon essentially consists.

8. Explain the formation of dew.

9. What is the law which expresses the loss of weight of a solid body when immersed in a liquid?

Surgery.

Monday, February 8th, 1886, from 2 P.M. to 5 P.M.

1. Describe the various conditions of an artery which may give rise to an aneurysm. Under what circumstances, in a case of popliteal aneurysm, would ligature of the femoral artery be imperative without waiting to test the effect of other measures?

2. What are the general external characteristics of the following calculi:—1. Uric acid. 2. Oxalate of lime. 3. Phosphate of lime. What is the explanation when two of these form a single calculus? Describe the microscopical appearance of crystals of oxalate of lime and uric acid.

3. What tissues does enchondroma most commonly affect? What are its general and microscopical characteristics?

4. Describe the causes, symptoms, and usual results of acute periostitis, and the treatment under each condition?

5. Describe the fractures to which the neck of the femur is liable, in what direction the force must be applied to produce either variety, and the treatment to be adopted in each.

6. What are the conditions known as "concussion of the brain," and in what respect do they differ from that of "compression"? What treatment should be adopted in "concussion of the brain"?

Anatomy and Physiology.

Monday, February 8th, 1886, from 10 A.M. to 1 P.M.

1. Certain bones enter into the formation of the orbit, describe the share which each bone takes in the construction of that cavity. Give a brief account of its contents, describing the relative positions of all the parts you name. (This does not include the anatomy of the eye.)

2. Describe the origin, distribution, and anatomical relations of the arteries and their branches which supply the foot with blood.

3. Describe the anatomical relations, connexions, and structure of the large intestine, giving also an account of its functions and of the processes carried on in that portion of the intestinal canal.

4. What are the origin, anatomical relations, distribution, and functions of the glosso-pharyngeal nerve and its branches?

5. Describe the dissection by which you would expose the lingual artery, giving an account of the relative position of neighbouring parts.

Medical Diary for the ensuing Week.

Monday, March 1.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Alex. Hill: On the Brain Mechanism of Smell and Sight.

ROYAL INSTITUTION OF GREAT BRITAIN.—5 P.M. General Monthly Meeting.

SOCIETY OF ARTS.—8 P.M. Prof. F. Guthrie: Science Teaching (Cantor Lecture).

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Casual communications by Drs. W. St. George Elliott and J. C. Foran.—Dr. Dudley Buxton: Physiology of Nitrous Oxide.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. A. Hughes-Bennett: Spastic Paralysis. Election of Officers and Council at 8 P.M.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Annual Meeting. Election of Officers and Council for 1886-87. President's Address.

Tuesday, March 2.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. Charles T. Newton: The Unexhibited Portion of the Greek and Roman Sculptures in the British Museum.

SOCIETY OF ARTS.—8 P.M. Mr. John Mackenzie: Bechuanaland and Austral Africa.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Shattock: Congenital Cystic Kidney.—Mr. Lockwood: Pistol-shot Wound of Cranium, &c.—Sir W. MacCormac: Tumour of Palate.—Mr. Bilton Pollard: Villous Tumour of Accessory Thyroid.—Dr. Gulliver: Malignant Disease of Thyroid in Myxœdema.—Mr. Pitts: Ossifying Sarcoma of Radius.—Dr. F. Taylor: Aneurysm of Septum Ventriculorum.—Dr. S. West: Cases of Aortic Aneurysm.—Mr. Clutton (for Dr. Floyer): Congenital Skin Tumour of Sigmoid Flexure. Card Specimens:—Dr. Payne (for Dr. Jacob of Leeds): Tumour of Finger.—Mr. Pollard: Dermoid Cyst of Testicle.—Dr. Lediard: Senile Ovarian Blood-cyst and other specimens.—Dr. Turner: Hepatic Cells in Blood of Portal Vein.—Dr. Carrington: Mitral and Tricuspid Stenosis.—Mr. E. H. Fenwick: (1) Fibro-sarcomatous Polypi from Bladder; (2) Papilloma of Bladder.—Mr. Mekins: (1) Dislocation of Cervical Spine; (2) Carcinoma involving both Superior Maxillæ.—Dr. Drewitt: Heart and Pericardium from a case of Rheumatic Nodules.

Wednesday, March 3.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Alex. Hill: On the Brain Mechanism of Smell and Sight.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Dr. Lewers: Case of Circumscribed Sarcoma of Uterus and Vagina.—Dr. Matthews Duncan: On Contraction, Inhibition, and Expansion of the Uterus.—Dr. George Coates: A case of Labour in a Primipara suffering from Mitral Disease.—Dr. Amand Routh: A case of Serous Perimetritis.

SOCIETY OF ARTS.—8 P.M. Mr. C. V. Boys: Calculating Machines.

Thursday, March 4.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. W. Boyd Dawkins: The Ancient Geography of Britain.

PARKES MUSEUM OF HYGIENE.—8 P.M. Mr. Shirley Murphy: Metropolitan Defences against Infectious Diseases.

HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Mr. R. Sisley: Retro-peritoneal Sarcoma.—Mr. A. L. Silcock: Cystic Sarcoma of Mesentery simulating an Ovarian Cystic Tumour.—Mr. W. Adams: Chronic Rheumatic Arthritis especially affecting the Hip-joint.

Friday, March 5.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Alex. Hill: On the Brain Mechanism of Smell and Sight.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Mr. Percy Dunn will show (1) Large Pulmonary Infarct; (2) Sarcoma of Testes and Cord; (3) Congenital Mitral Stenosis with General Cardiac Hypertrophy, weight of heart 27 oz.—Brigade-Surgeon Curran: Collection of Drawings and Photographs illustrative of Venereal Disease and Goitre in the Himalayas.—Mr. Swinford Edwards: On Urethral Fever, with Records of Three Fatal Cases.—Mr. Hurry Fenwick: On the Precautions to be adopted in the withdrawal of Residual Urine.

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Dr. Alexander Macalister: Anatomical and Medical Knowledge of Ancient Egypt.

Saturday, March 6.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Rev. C. Taylor: The History of Geometry.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

MEDICAL SECRETS AND LAW COURTS.

P. E. J.—A medical man may be compelled in a court of law to divulge secrets communicated to him in his professional capacity. This is a matter beyond his choice or control, and involves no discredit to him, as the divulgence of secrets in vulgar ways of gossip, or short of the demands of the law, certainly would. In the particular case mentioned, and in the mental condition of the patient, the statements made to the medical man have very little value in themselves as evidence.

Dispenser.—1. We do not think any risk would be incurred by so doing.—2. Yes.

THE ARMY MEDICAL STAFF.

To the Editor of THE LANCET.

SIR,—In an annotation in your issue of the 6th inst. (p. 273), entitled "Medical Education in Russia," the burden laid on medical men by the State is commented on. I do not think the conditions so hard as those imposed by the British Government on officers of the Army Medical Staff, who voluntarily retire after ten years' service, with what they are pleased to call a "gratuity." These officers are liable to serve again in case of "national emergency" (i.e., whenever the Army Reserve is called out), until they complete the age of fifty-five years; so that a medical officer joining at the age of twenty-one and retiring at the age of thirty-one forfeits his liberty for twenty-four years for £1000, for which he has served ten years. While he is re-serving, he receives the pay of the rank in which he retired; but such fresh service only counts towards the period required for increased gratuity or for pension, five and ten additional years respectively. Is it likely a national emergency would continue for five years, or that such a series of emergencies would occur as would enable a medical officer, from time to time, to complete the additional periods required? A retired medical officer who has purchased a practice with his "gratuity" may be called on to re-serve. He must sell his practice, probably at a heavy loss, and rejoin with the foregoing glowing prospects before him! The State does not incur any expense in the education of Army Medical Staff officers, except that involved in the Netley course. Surely, ten years' service repays them for that outlay. I do not suppose they would give medical men the "gratuity" could they now secure their services without that inducement. I remain, Sir, yours faithfully,

W. J. LE GRAND,
Late Surgeon, Medical Staff.

Rudworth-street, S.E., Feb. 10th, 1886.

"PSORIASIS ECZEMATOSUS."

To the Editor of THE LANCET.

SIR,—Allow me to suggest to your correspondent, "Sans Succès," the chrysophanic ointment, spread on muslin, prepared by P. Beiersdorf, Apotheker, Altona, Wohlers Allee, No. 40.

I am, Sir, yours truly,
J. S. GRUBB.

Ealing, W., Feb. 20th, 1886.

INSURANCE OFFICES AND INADEQUATE MEDICAL FEES.

Dr. Fred. E. Pearse of Frome forwards us a correspondence which he has had with the 'Sickness and Accidental Assurance Association, Limited,' including eleven or twelve letters, in which he had to fight, inch by inch, for a proper fee of one guinea, and at length got it only by the determined threat of the County Court. The office at first sent him 7*s.* 6*d.*, and justified itself by saying that this had been stated at the outset to be the fee given by the office. Dr. Pearse denied having received any such statement at the outset, and with proper dignity declined the successive advances of the office by half-crowns or more. His example is one to be followed.

Mr. George A. Hawkins-Ambler.—We are afraid the publication of the letter might give rise to a discussion on a matter which is scarcely within our province.

ATTENDANCE BY UNQUALIFIED ASSISTANTS.

To the Editor of THE LANCET.

SIR,—Allow me to state that Mr. Bowell of Hunslet is not a raw student from the Medical School working for a low salary, or for nothing but his board and lodgings, as are a large number of the assistants employed in Leeds, but is a gentleman forty-six years of age, of twenty-seven years' practical experience, who has attended 10,000 cases of midwifery, and has conducted solely two large practices in Hunslet for his uncle and cousin, the late Drs. Gisburn. I pay Mr. Bowell a salary of £150 per annum. It is true he lives in his own house (the property of his wife); but I fail to see any harm in that. He lived in it when he was conducting the practices named above, and had his name on the house, just the same as he has now. Since I obtained his services no alteration has been made, and it is well known in Hunslet that he is unqualified. He is, however, respected thoroughly by every class of the community. With one or two exceptions, he is on friendly terms with the medical men of the locality; and I can assure you that for years the leading consultants of Leeds have met him when he was in sole charge of critical cases. He always acts under my advice, and has less of his own way than when he was acting for his cousin, the late Dr. Gisburn. Dr. Gisburn, for certain reasons, was unable to see his patients frequently, and so most of the work fell upon Mr. Bowell, who was the means of saving his cousin's practice from being lost. In fact he was better known in Hunslet than was his employer. This is not so now. Where Dr. Gisburn went once to see a patient, I go thirty times or more, and everything is under my complete control. The people at Hunslet are very angry at the way Mr. Bowell and I have been treated in this matter, and it would certainly go hard with one or two professional parties if I mentioned their names in connexion with getting up this petty persecution. How many unqualified students in Leeds are entrusted with important cases whilst their masters are elsewhere? How many branch practices are carried on by unqualified gentlemen for miserable salaries? Let the profession at Leeds answer these questions; and then, if the majority are not guilty of illegal practices by employing unqualified assistants, let them put down one who does employ an unqualified gentleman.

In justice to myself, I ask the insertion of this letter in your valuable journal. I may also add that I can give all names, if necessary.

I am, Sir, yours faithfully,
H. ARTHUR ALLBUTT, M.R.C.P., &c.

Leeds, Feb. 18th, 1886.

THE CASE OF H. P. FREUND.

To the Editor of THE LANCET.

SIR,—The case of Herbert Percy Freund has on several occasions been alluded to in THE LANCET, and once more is specially mentioned in an annotation in your issue of the 20th inst. It may not be generally known that this unfortunate man, who has been repeatedly brought before the London magistrates for religious monomania, and has been by them sentenced to various terms of imprisonment, owes his breakdown to overstrain whilst working for the Bachelorship in Medicine of the London University. At the City of London School, where he was a schoolfellow of mine, he was remarkable for his jovial good humour and geniality. Whilst holding a good position in the sixth form he won the St. Thomas's Hospital Scholarship, which covered the cost of the fees of his medical curriculum on the condition of his successfully passing his examination when due. He was consequently most anxious not to fail from the fear that he might thus lose his scholarship. The fact that in spite of his anxiety he passed the First M.B. Lond. in 1874 within a year and three-quarters of the date of the commencement of his medical study was sufficient proof of his ability, more especially as he secured Honours in the Preliminary Scientific Examination at the end of his first year. The strain, however, told, and shortly after the First M.B. Examination he became eccentric and depressed, took to ascetic habits and a solitary life, and was unable to continue study, becoming later on a confirmed religious monomaniac. May I ask whether something could not be done for him, at least, by old members of the City School (I believe he belonged to the "John Carpenter Club") or of St. Thomas's Hospital, if only in the way of placing him in an asylum, so as to prevent the scandal of his frequent appearances in the police courts. I for one would be very glad to help or to hear of others similarly disposed. I am, Sir, yours faithfully,

W. P. MEARS, M.D.

University of Durham College of Medicine, Newcastle-on-Tyne, Feb. 20th, 1886.

INDISCRIMINATE SALE OF NARCOTIC POISONS TO THE PUBLIC.

To the Editor of THE LANCET.

SIR,—So many cases of poisoning have been reported of late in the medical and daily papers, that it is high time something was done to put a stop to the indiscriminate way in which chemists supply narcotic and other poisons to the public at large without medical order or prescription.

Two cases have within the past three months come prominently before my notice on board ship, which tend to prove how easy a thing it is for a layman to become possessed of dangerous and subtle poisons. Both cases occurred on board one of the Cape mail steamers. The first was a woman (a third-class passenger) who was proceeding to the Cape. Having occasion to visit her in her cabin, I was astonished to find a quart bottle full of laudanum, which she took twice daily in tablespoonful doses. She told me she never had the least difficulty in getting the laudanum at the chemist's, and as soon as the bottle was finished she had it refilled. This woman was undoubtedly afflicted with that terrible opium craving, but she was able to purchase, only too easily, the drug which will so surely cause her complete dissolution. The other case was a young gentleman of considerable fortune, who was taking a voyage to the Cape for the benefit of his health. He had with him two large bottles of solution of morphia, which he procured at a chemist's before leaving England, and he was in the habit of taking about sixty drops of this nearly every night at bedtime, to induce sleep, as he told me. This young man was strongly addicted to drink, and frequently retired to bed in a half intoxicated condition; whilst in this state he would pour out the morphia solution into a tumbler, add some water and drink it off, afterwards retiring to bed. Fortunately for him no ill-effects followed; but how different might have been the result!

These are two cases only out of many which I have observed on board ship, and they go far towards showing that we are not likely to see our mortality list from poisoning diminished so long as the public are supplied wholesale with these narcotic and dangerous poisons. Now that our profession, numerically speaking, is so much better represented in Parliament, let us hope that at least one of our medical brethren in Parliament will find time to turn his attention to this most important subject. I am, Sir, yours very truly,

HERBERT E. WRIGHT, L.R.C.P., &c.,
Feb. 17th, 1886. Senior Surgeon, Castle Mail Packets Co.

Physician and Surgeon.—A medical and a surgical qualification from any of the Royal Colleges will entitle their possessor to the privilege mentioned. These diplomas can be obtained in either division of the United Kingdom.

G. P. is the best judge of the proper fee to be charged. There is no rule that would apply, apart from the circumstances of the special case.

A QUESTION IN MEDICAL ETHICS.

To the Editor of THE LANCET.

SIR,—Your decision in the following case would be valued:—

A is called in to see B's wife, prescribes for her, and gives directions notifying that the symptoms will probably not completely subside within a month. Right days afterwards, at the third visit, A is understood to consider the patient so much better that his visits are then discontinued. Within a week or so, the sickness returning as bad as at first, B sends for C, without saying anything to A or C. When A discovered this he waxed wroth, but B justified himself on the grounds that A had ceased to attend. Is this justification sufficient, or does B owe A an apology? It may be mentioned that no fees have passed, and that B had been on occasions a patient of both A and C, but that Mrs. B, being a bride recently arrived, had not been a patient of either before.

I am, Sir, yours truly,
Feb. 23rd, 1886. ALPHA.

*** B did not act with candour and consideration to A. He is not to be justified on the plea that A's attendance had ceased. He owes an apology to A. C owes it to A to say as much to B as we have said of his conduct.—ED. L.

A Subscriber.—Supposing the case to be as stated, A is very badly used by B, and would be justified in seeking some legal redress if he cannot prevail on him to submit the questions in dispute to friendly arbitration.

H. W. H.—Dr. Weir Mitchell of the United States has published a book on the subject.

"MUMPS."

To the Editor of THE LANCET.

SIR,—Allow me, in answer to Dr. Hutchinson's request for information on the above subject (THE LANCET, Feb. 20th, p. 382), to say that, in my opinion, the rule referred to is a good one, and should be enforced against all infectious diseases. The initial stage both of mumps and of measles is highly infectious. School officials should not allow children to attend when any members of that family are ill, even with sore throat, until the nature of the illness is ascertained, and never while there is infectious illness at home. I wish this was the rule in all schools. I am, Sir, your obedient servant,

Feb. 23rd, 1886. WILLIAM SQUIRE, M.D.

MEDICAL STRIKE AND THE MEDICAL INSTITUTION AT LIVERPOOL.

We learn from a paragraph in the *Liverpool Mercury* of Feb. 5th, that at a meeting of the Medical Institution a committee of the leading medical gentlemen of the city was chosen to investigate charges brought against a medical officer of one of the charities of performing reckless operations without consultation with his colleagues, whose name and eminent position lend confidence to any charity with which they are associated. This is a serious paragraph to appear in a daily paper, and we should like to know more of the facts which constitute its explanation.

Vindiciæ.—1. There is no absolute rule of co-operation between a principal and his assistant, except such as is implied in their essential relationship. A principal is always entitled and expected to supervise cases, however competent his assistant may be. The only thing necessary in such relations is mutual respect and consideration.—2. We cannot give the composition of the tincture referred to.

W. H. O. has not enclosed his card.

"FRIENDLY SOCIETIES' MEDICAL INSTITUTIONS."

To the Editor of THE LANCET.

SIR,—There is sure to turn up some opponent to almost every reformer; and I cannot conceive anyone writing in support of the above institutions. Your correspondent, "Medical Officer (F.S.M.I.)," who writes in your issue of to-day, has not had much experience of the working man, or he would not be so ready to uphold this system of hard labour for our profession. I have been connected with two of the largest amalgamated societies in England, as one of their medical officers; and I can safely pledge myself that so long as I can support myself in any other employment I will never accept office under them again. The work is hard, unthankful, unprofitable; insults, abuse, and inconsiderateness abound. As to members being qualified to receive the benefits of such institutions, there is a shameful disregard as to conditions of admission. New members are almost forced upon the doctor; because if they are not passed, or receive certificates of any kind when they want them, there is sure to be a "row" and some fault-finding, either in the club or committee, with the medical officer. Besides, many outsiders who are well able to pay for private medical attendance join as dispensary members, paying very limited charges, having equally as much benefit as club members, and certainly swallowing more physic than they could obtain for twenty times the amount from a private practitioner. I believe that the club system has done more to ruin our profession than enough. I do not say that the profession is not to blame; but this degrading and "lumbago" sick-certificate work is becoming a working-man's privilege, and as a result bringing contempt on us. No one can deny that there are some decent working-men who are averse to taking advantage of our cloth; they are exceptional. Lastly, the persons who are reaping a rich reward out of our labour are the representatives of these associations. There is a secretary, treasurer, president, vice-president, and committee, all of whom are paid out of the subscriptions. Hence the doctor has to do more work to support these gentlemen.

I am, Sir, yours faithfully,
Feb. 20th, 1886. A RETIRED CLUB-ASSOCIATION DOCTOR.

L.S.A.—Not in the present state of the law.

Dr. Lewers.—In an early number.

"SYMPATHETIC IRRITATION OF THE PNEUMOGASTRIC."

To the Editor of THE LANCET.

SIR,—Upon the principle that giving tone to the nervous system lessens its irritability generally, and believing as I do that this is best and most speedily accomplished by full doses of quinine, especially if good sleep be procured at the same time, I would advise your correspondent, Dr. Towers-Smith, to give to his patient the third part in a wineglass of water of the following mixture every night:—℞ Disulphate of quinine, ʒss.; dilute hydrobromic acid, ʒiss.; hydrate of chloral, ʒii.; syrup of oranges, ʒvi.; to three ounces of water. If after giving the above three doses there should still be irritability, an addition may be made of ten minims of the solution of morphia to each dose, and the three doses repeated. I am, Sir, yours truly,

Feb. 22nd, 1886. A READER OF "THE LANCET."

Mr. Dyer.—The qualifications named are undoubtedly high, but qualifications only in medicine.

USE OF IODIDE OF POTASSIUM IN ANEURYSM.

To the Editor of THE LANCET.

SIR,—The use of this drug in heroic doses for the treatment of aneurysm is somewhat older than Dr. Burney Yeo seems to be aware of. In the wards of the Royal Infirmary of Edinburgh Dr. Warburton Begbie had a number of cases treated in this way, some of the details of which I remember very well, as early as 1861–62. Many of my fellow-students of that time undoubtedly will remember the Highland packman, Macalpin, who had a large aneurysm perforating his sternum, and who yet was able to do the hard work of his business so long as he was under the influence of iodide of potassium without any progress of the disease. I do not know if the treatment was originated by Dr. Warburton Begbie, but certainly he had it in habitual employment, and was extremely successful with it. I am, Sir, yours faithfully,

Birmingham, Feb. 7th, 1886. LAWSON TAIT.

INTERMITTENT ALBUMINURIA WITH OXALURIA.

To the Editor of THE LANCET.

SIR,—May I say in your valuable columns regarding the coincidence of intermittent albuminuria with oxaluria that I have often found these symptoms follow the repeated ingestion of sauces or pies made of the stalks of common rhubarb, sold at the greengrocers' after January in each year. It was the practice of students at Yale Medical School in former days to secure fine large crystals of oxalate of lime for microscopy by eating these foods and collecting the crystals from their own urine subsequently. The practice was attended with discomfort to many from prolonged backache and irritable bladder, and in these cases I have found albuminuria coincide with the oxalates, lasting while the rhubarb was indulged in. I have good reason for thinking that cider, drunk freely, is competent to induce similar symptoms.

I am, Sir, very respectfully yours,

Ilford, Feb. 22nd, 1886. H. W. JONES, M.A., M.D. (Yale, U.S.A.).

Mr. H. Martin, M.B.—This being the first examination of surgeons of medical staff for promotion to surgeon-major, the questions for examination have not yet been published. Many years ago, when the examination was in force, the questions were published in the departmental Blue Books.

Dr. James Adam.—Yes, shortly.

LONDON FEVER HOSPITAL.

To the Editor of THE LANCET.

SIR,—In the report of the annual meeting of the governors of this institution, which appeared in THE LANCET of last week, the paragraph beginning—"The expenditure amounted to £8543, which was an increase of £1842 over that of the preceding year," should read was a *decrease*. I am, Sir, your obedient servant,

Feb. 23rd, 1886. E. BURN CALLANDER, Sec.

SCARLET HOSIERY.

To the Editor of THE LANCET.

SIR,—Will you allow me to draw the attention of the medical profession to the presence of arsenic in scarlet socks and stockings? A friend of mine suffered rather severely last year by wearing such a pair; and only last week I extracted two decigrammes of the poison from one pair, and a decigramme and a half from another. Surely, manufacturers should be compelled to send out their goods worn next to the skin free from a poison so easily absorbed.—I am, Sir, yours obediently,

Marylebone-road, N.W., Feb. 17th, 1886. JOHN WOODLAND.

Mr. A—— (Cheapside) is thanked for forwarding the cards.

Dr. Blenkinsop.—Yes, if not too long.

E. W. B.—No.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

A Clinical Illustration OF CERTAIN PHASES OF THE RHEUMATIC DIATHESIS.

By W. B. CHEADLE, M.D., F.R.C.P.,
PHYSICIAN TO ST. MARY'S HOSPITAL, SENIOR PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE collection of patients in my wards at the Hospital for Sick Children at the present time affords such an excellent illustration of certain points raised in my lectures on Diseases of the Heart in Children, published in THE LANCET of Oct. 17th and 31st last, that I venture to give a brief account of them. The points in question are more especially the connexion of the slighter degrees of rheumatic arthritis and of other and less common phases of true rheumatism with organic disease of the heart and with chorea, and the influence of hereditary or constitutional tendency as a predisposing cause. The collection of patients, I may add, is a fortuitous one—a pure chance medley of cases admitted in the ordinary way without selection or design. They number in all twenty-two, and each has been examined (1) as to the occurrence in the patient of any distinct acute or subacute joint affection which could be classed as rheumatic—i.e., evidenced by swelling, stiffness, tenderness, and pain, and by the existence of subcutaneous tendinous nodules, of erythema, or other sign judged to be indicative of the rheumatic tendency; and (2) as to the occurrence of any similar manifestations in near blood-relatives. In this investigation I have had the valuable assistance of the registrar, Dr. Chaffey; and we have not been content with mere routine and general questions as to the occurrence of rheumatism or rheumatic fever, but have made minute specific detailed inquiries as to clinical symptoms, so as to verify statements and identify the affections with which the patients or their relatives might be credited. Similarly, we have not been content with a general inquiry as to whether such and such a disease was in the family, but have inquired into the medical history of the various members and relatives of the family as far as possible individually. It has been most instructive and suggestive to find how, in many instances, the original clinical history, taken in the ordinary way, has been modified by the closer examination of the further special inquiry.

In order that the significance of the following synopsis may be more readily understood, I have marked as Class A all cases in which rheumatic manifestations occurred in the patient; those in which rheumatic affection could be traced in blood-relatives of the first degree (i.e., father, mother, brothers, or sisters) as Class B; and those in which like affections occurred in relatives of the second degree only (i.e., grandfather, grandmother, uncles, aunts, or cousins) as Class C; those in which no rheumatic history of any kind could be found being left unmarked.

Synopsis of Cases.

CASE 1.—Henry S——, aged eleven. Purpura hæmorrhagica. No rheumatic affection in the patient. No rheumatic affection can be traced in any relative on either the father's or mother's side.

CASE 2.—William M——, aged five. Cerebral tumour. No rheumatic affection of any kind in the patient. No rheumatic affection in any relative on either side.

CASE 3. Classes A, B (?), C (?).—Isaac H——, aged ten. Heart disease (mitral stenosis and regurgitation, with advanced hypertrophy and dilatation). Three attacks of slight arthritis; knees, elbows, wrists, and knuckles red, painful, and stiff. The last attack occurred a fortnight ago, and was attributed to chill from sitting outside an omnibus in a cold wind. There are several subcutaneous nodules on each elbow. The boy's father died young of heart disease, from which he had suffered since childhood (probably rheumatic). The patient's aunt—the mother's sister—had chorea when a child; her mother had chronic rheumatism (not definite).

CASE 4. Charles H——, aged six. Xeroderma and eczema. No rheumatic affection in the patient. No rheumatic affection in any relative on either side.

CASE 5. Edward C——, aged seven. Late rickets. No rheumatic affection in the patient. No rheumatic affection in any relative on either side.

CASE 6. Class A.—Ernest W. M——, aged five. Chorea For the last three weeks the fingers of both hands were swollen, tender, and stiff, so that he had difficulty in closing them; pain, stiffness, and tenderness of right knee. Over the great vessels at the base of the heart the second sound is replaced by a well-marked bruit (aortic regurgitation). No rheumatic affection in any relative on either side.

CASE 7.—Frederick H——, aged four. Empyema. No rheumatic affection in patient. No rheumatic affection in any relative on either side.

CASE 8. Class B (?).—Arthur J. P——, aged eleven. Hydatid of liver. No rheumatic affection in patient. A sister has had pain and stiffness of the joints; never laid up with it, but probably rheumatic.

CASE 9.—Walter C——, aged ten. Eczema. No rheumatic affection in patient. No rheumatic affection in any relative on either side.

CASE 10. Class C (?).—Francis W——, aged three. Infantile paralysis. No rheumatic affection in patient. Maternal grandfather and uncle had rheumatic fever (doubtful).

CASE 11. Classes B, C.—Joseph M——, aged ten. Chorea. The patient has had no attack of arthritis; no erythema. Has no affection of the heart, or any condition which could be deemed rheumatic, unless it be the chorea. But the father has had rheumatic fever; the mother's brother had rheumatic fever and chorea as a child, and heart disease, of which he died. The mother has "rheumatism," her father and mother likewise. The father's mother had "rheumatism," and his brother, but the exact nature of these affections is not with certainty ascertained.

CASE 12. Walter H——, aged seven months. Rickets. No rheumatic affection in patient. None in any relative on either side.

CASE 13. Matilda Jane S——, aged eight. Hemiplegia. No rheumatic affection in patient. The family history could not be obtained.

CASE 14. Class C (?).—Harry C——, aged nine. Acute nephritis. No rheumatic affection in the patient. The paternal grandmother had "chronic rheumatism"; the aunt on the mother's side had chorea as a child.

CASE 15. Classes A, B.—James H——, aged eight. Heart disease (mitral stenosis and regurgitation, with marked hypertrophy and dilatation). Two attacks of slight pain, stiffness, and swelling of knees and ankles; the first eighteen months ago; the heart said to have been affected then. One attack of rheumatic fever six months ago. The mother has had rheumatic fever.

CASE 16. Class B (?).—Harry B——, aged four. Bronchitis. No rheumatic affection in patient. A brother has "rheumatics," a sister "rheumatism, heart disease, and consumption." The exact nature of these affections could not be satisfactorily ascertained.

CASE 17. Class A.—Charles G——, aged ten. Chorea. Six weeks ago had slight pain, stiffness, tenderness, swelling of wrists, fingers, and knees, lasting fourteen days. Presystolic murmur and thrill. Marked erythema; raised purple blotches; urticarious wheals. No history of rheumatic affection in any relative on either side.

CASE 18. Class C.—Albert H——, aged five. Empyema. No rheumatic affection in the patient. Mother's brother had rheumatic fever and heart disease.

CASE 19. Classes A, B, C.—Ernest Q——, aged nine. Mitral disease of heart.[1] Pain and stiffness of joints off and on for the last six months. For the last four days, elbows, knees, and ankles stiff and tender. The patient's sister is now in Victoria ward of this hospital with acute rheumatism and heart disease. The father's sister has had rheumatic fever; the mother's father had rheumatic fever.

[1] This patient has since developed chorea in hospital.

Digitized by Google

CASE 20. Class C.—William J——, aged four. Rickets; otorrhœa. No history of rheumatism in patient. Mother's mother had rheumatic fever.

CASE 21. Classes A, C.—Rose W——, aged eight. Chorea. Mitral disease of heart, hypertrophy, and dilatation. Subacute rheumatism six weeks ago. Ankles, knees, and wrists red, stiff, swollen, and tender; nodules on the elbows. The mother's sister had rheumatic fever.

CASE 22. Class A.—George W——, aged six. Mitral disease of heart (systolic and presystolic murmurs, and some dilatation). No joint affection. Subcutaneous nodules on both elbows and both knees. No history of rheumatic affection in any member of the family on either side.

It will be seen that in the whole 22 cases there are 4 of organic heart disease and 4 of chorea, the remaining 14 being made up of very varied forms of children's diseases. Now, of the 4 cases of heart-disease all are included in Class A, and 3 out of the 4 cases of chorea; but no case of any other disease out of the remaining 14. In Class B are included 2 of these 4 cases of heart-disease and the remaining case of chorea; also probably, but not certainly, the case of bronchitis, and that of hydatid of the liver—i.e., 2 out of the 14 heterogeneous cases. In Class C come also 2 of the 4 cases of heart affection, 2 of the 4 cases of chorea, while of the 14 heterogeneous cases only one case of empyema, with probably, but not certainly, the case of infantile paralysis and that of acute nephritis. Moreover, it will be seen that 1 case of heart disease appears in all three classes; another in Class A, and probably in Classes B and C also; and a third in Classes A and B. Again, 1 case of chorea appears in both Classes A and B, and 1 in both Classes A and C. Not one of the 14 heterogeneous cases occurs in Class A at all, and, including even doubtful cases, 2 only in Class B and 2 in Class C, but not one in the two Classes B and C together. In other words, in all 4 cases of organic disease of the heart, and in 3 out of 4 cases of chorea, there is a certain history of rheumatic affection in the patient. In one of these cases of heart disease there is, in addition to personal rheumatism, evidence of rheumatic affection in blood-relatives of both first and second degree; in another, in addition to personal rheumatism, probably in relatives of both first and second degree also; and in a third, again in relatives of the first degree, in addition to personal rheumatism. In two of the cases of chorea, in addition to the rheumatism in the patient, there is evidence of rheumatic affections in blood-relatives, in one case of the first and in another of the second degree; while the case of chorea, in which there is no evidence of any rheumatism in the individual, there is double history of rheumatic affection in blood-relatives of the first and second degree. The contrast between these cases of heart disease and of chorea and the remaining cases in respect to rheumatic connexion is most striking. In not a single instance could any phase of rheumatism be traced in the individuals themselves; in two instances only, including even doubtful cases, in blood-relatives of the first degree; in two more in blood-relatives of the second degree; but in none was there evidence of rheumatic taint in relatives of both the first and second degree together. It is not to be inferred that the incidence of the rheumatic connexion exhibited in the present tenants of the wards is exactly representative. The proportion in chorea, for example, is beyond the average, and the frequency of rheumatic taint in the general cases is probably somewhat below it. The picture is too small, but as far as it goes it is accurate and true; the general lesson it teaches is trustworthy, and is, I think, very striking and suggestive.

ROYAL ALBERT ASYLUM, LANCASTER.—On Feb. 26th Lord Winmarleigh, Chairman of the Central Committee, presented certificates of proficiency in "first aid to the injured," awarded by the St. John Ambulance Association, to thirty-three of the officers, attendants, and nurses of the asylum. His lordship drew attention to the extent and value of the work of the Association, and expressed gratification that the scheme of instruction, which had proved so serviceable in many centres of industry, had been utilised, through the lectures of Dr. Shuttleworth, the medical superintendent, as a means of improving the qualifications of those on whom devolved the personal care of the afflicted inmates. It may be mentioned that no less than sixty-seven of the institution staff joined the classes for instruction and thirty-four entered for examination.

Clinical Lecture
ON
CATARACT.

Delivered at the Eye Infirmary, Newcastle-on-Tyne.

BY C. S. JEAFFRESON, F.R.C.S. ED.,
SURGEON TO THE INFIRMARY.

(*Continued from p. 388.*)

HAVING spoken of the symptoms of cataract as they present themselves in elderly persons, let us say a few words upon those attending lamellar and some other forms of congenital cataract which are usually first noticed in children and young persons. Lamellar or laminar cataract not infrequently occurs in children of impaired constitutional vigour. In not a few cases a history of inherited specific taint may be obtained, and not infrequently the subjects of them are liable to convulsive attacks in infancy. There may be evidence of changes in the nervous centres, with amblyopia and nystagmus. If the cataract is not marked and giving rise to unmistakable objective symptoms, its existence is usually overlooked till the time of life arrives when children commence to use their vision for amusement or educational purposes. It is then noticed that the child has difficulty in seeing as clearly as his fellows. He not infrequently stumbles over things in broad daylight, and at dusk his vision improves. Small objects he wishes to look at he places close to his eyes like a myopic person, and the complaint usually made by the parents is that he is very short-sighted. Sometimes objects are placed laterally to get a clearer view of them. The explanation of all these symptoms is simple. It is clear that when the pupil dilates at night a larger piece of the lens is uncovered, and some of the transparent margin being uncovered allows a clearer view of objects to be observed. The patient puts objects nearer to him because he sees them under a larger angle, and holding them laterally enables the rays to pass through the marginal and clear parts of the lens. Although when the pupil is contracted it is not always easy to recognise this form of cataract with the naked eye in ordinary daylight, owing to a transparent layer of the lens intervening between the cataractous portion and the observer, oblique illumination with dilatation of the pupil immediately reveals the true state of matters. I need not tell you that the symptoms will vary in intensity in accordance with the amount of lens structure which is affected, and its density and both these circumstances are liable to very great variation. Some patients manage to struggle through life with the affection when it is slight and stationary. In others some operative treatment soon becomes necessary. I fear, however, that the time at my command will scarcely enable me to deal with these to-day.

Now, gentlemen, I will pass rapidly in review the different methods of treatment cataract necessitates. I need not tell you that it is a malady which admits of no medical treatment. Changes in the transparency of the lens once effected, its original condition is never restored. I must make an exception to this rule in the case of diabetic cataract, if certain cases which have been reported lately are correct. It is possible for very considerable degrees of opacity to clear away and vision to be restored. Personally, I have seen many cases of diabetic cataract in all stages, and I never have seen any such changes as those to which I refer, even when the elimination of sugar had been almost completely checked. I have always found the lens unchanged, and I confess to a certain amount of incredulity, although I cannot pass the matter over. I am inclined to think, in some of these cases at least, that a mistake has occurred. In diabetes scotomata frequently occur, producing great amblyopia, and if in conjunction with these symptoms the greenish reflex from the lens which is so frequent in age and some other conditions were present, a mistaken diagnosis of cataract might easily be made by an inexperienced person unassisted by oblique illumination or the ophthalmoscope. Then, if the scotoma cleared away and vision were restored, an impression that the lens had regained its transparency

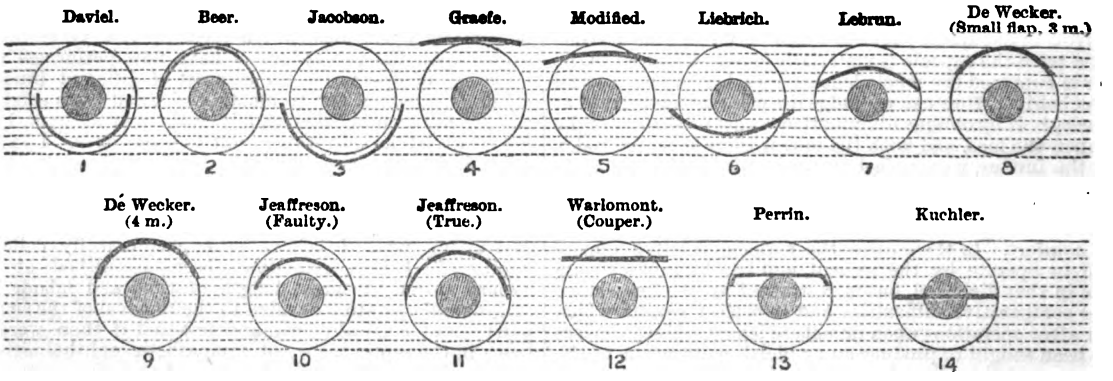
Digitized by Google

would be produced. Of course proper medical treatment in a general way is useful in many cases of cataract. It is a disease of degeneration, and not infrequently there is evidence of some flaw or crack in the constitution, proper attention to which may delay the advance of the malady. Not a few suffer from albuminuria, atheromatous degeneration of the vessels, or gout, and it is well in all cases to institute a careful examination of the urine, the heart, and the great vessels. You may discard, too, all the nostra which savour of quackery, in the shape of the local use of ammoniacal solutions, phosphorised oil, and electricity; they are absolutely of no avail. When the cataract is already considerably advanced, and in nuclear cataract sometimes at a comparatively early stage, artificial mydriasis induced by atropine is often of service in improving sight, but it should be used with caution, and not without first having ascertained that no glaucomatous tendencies exist. Half a grain of sulphate of atropia dissolved in one ounce of water is usually quite sufficiently strong, or you may use the hydrobromate of homatropia in the form of one grain to the ounce. Its effect is not so prolonged as atropine, and it requires to be more frequently applied; but it is less likely to induce glaucomatous affection, though not absolutely free from this danger. Having fulfilled these temporary indications, we must be patient and wait till the time comes for operative treatment.

What is the proper time for surgical treatment? That is a question which has been debated for years without being satisfactorily answered, and indeed it is a question which is not open to any categorical reply. An infinite number of circumstances must influence it in each individual case. In most cases it is advisable to wait till the cataract is what we call mature. That occurs when the whole of the lens matter has become degenerated. The lens then lies like a ripe fruit in its capsule; it is not absolutely loose, but its connexion with the capsule is materially loosened, and when the latter is ruptured the whole lens escapes, leaving no cortical matter behind. How can we judge if a cataract has arrived at maturity? If by oblique illumination we get no shadow of the iris upon the lens, and with the mirror there is no red reflex from the fundus, we may feel pretty certain that the cataract is mature. Now there are many cases in which this condition of maturity is most tardy in occurring; a degree of opacity is reached which prevents all useful occupation being followed with comfort. In these cases the surgeon is often opportuned to operate by the patient, and has himself a strong desire in that direction, but is restrained by the knowledge of the comparative difficulties and imperfect results which occur after operations upon immature lenses. Many devices have been sought to produce an artificial maturation of the cataracts and thus diminish the painful period of suspense in which these patients are kept. Massage of the globe has been much vaunted. It may be performed alone, or a primary iridectomy may first be performed and the massage applied direct to the lens by stroking it with a blunt instrument. This operation requires much care and delicacy in its performance, as there is danger of detaching the lens from its zonula. An iridectomy alone is very efficacious sometimes. I have very frequently adopted it with advantage, and it has this to recommend it, that it facilitates the steps of the subsequent extraction when it becomes necessary, although many patients object to it because it makes two operations necessary instead of one. Puncturing the lens is another method of producing artificial maturation, but it is not unattended with danger, and is not always so successful as one would *à priori* suppose. In nuclear and cortico-nuclear cataracts the sclerosis of the lens fibres renders them inapt to imbibe the aqueous humour. We see this sometimes where an attempt has been made to perform the old operation of couching, and after some forms of accident, when the lens may be seen to lie for years in the anterior chamber without undergoing any alteration.

As a cataract may be immature, so also it may become if left to itself hyper-mature. This is a condition which is also less favourable for operation. The lens becomes small and contracted, it may even become loose in its capsule, its ligamentous attachments become less firm, and there is danger of detachment; the iris is more sluggish and less elastic, and the lens has difficulty in passing through it; the vitreous becomes softened, and altogether the immediate dangers of an operation are much greater than when the lens is immature. Hyper-mature cataracts are not infrequently seen in patients coming from distant country districts. They are the outcome of a popular and widespread fallacy—for which, I regret to say, the profession are in no small degree responsible—that in cataractous patients no operation should be performed until the patient is practically blind. The degree of blindness is not always in direct proportion to the maturity of the cataract. Some persons with mature cataracts can see fairly well; nevertheless, they should be operated upon, and any delay after that period gives opportunities for regressive changes to develop themselves.

What rule should we adopt with regard to operations in cases of persons suffering from monocular cataract, or in those in which the cataract is very unequally developed in each eye? In cases of monocular cataract, the result of disease or traumatism, I usually explain the circumstances of the case to the patient, pointing out the advantages he may gain in the event of success from the assistance of the operated eye in binocular vision, its cosmetic advantages, and the chances, remote though they may be, of accident or disease some day affecting the good eye at a time when, from disuse and regressive changes having set in, an operation upon the other would be too late to be attended with the same measure of success, if any. When both eyes are cataractous, but one in advance of the other, I always advise and urge an operation to be performed when the first lens arrives at maturity. The infinitely small risk of sympathetic ophthalmitis developing in the unoperated eye is not, to my mind, worth taking into consideration; at all events, it in no way counterbalances the advantages of the proceeding, which when successful saves the patient from being withdrawn for any lengthy period from occupations which may have great importance for him. But, gentlemen, as I said before, in all these matters no hard and fast line can be laid down; each case must be judged upon its merits. I have not that dread of sympathetic inflammation occurring as the result of cataract operations which seem of late years to have grown upon the profession. I have now performed many hundreds of operations for cataract of different kinds, including congenital and traumatic cases, and I can safely say that, to my own knowledge, either direct or indirect, I have not seen such an untoward result to occur once. I have no doubt it does occur sometimes, and more frequently in some clinics than others,—notably where the so-called peripheral operations are performed, and the wound is subjected to a process of pulling about and unnecessary manipulation in performing what I believe is euphemistically called its "toilette." I have sometimes been astonished at what seemed to me the great length of time and labour some continental operators devoted to the removal of the smallest particles of cortical débris, and felt that if there were any truth in the septic theory of sympathetic ophthalmitis, the danger of so much manipulation and such frequent introduction of instruments within the eyeball must be much greater than that of leaving small pieces of cortex untouched. But I shall refer to this matter again.



Now, gentlemen, having made up your mind that an operation is necessary, what method are you to choose? Perhaps no operative procedure in the whole range of surgery offers such an *embarras de richesse* as that of removing a cataract. The cornea, corneo-scleral junction, and sclerotic margin have been divided in almost every conceivable direction and extent by instruments of innumerable shape and form. The names of inventors of cataract operations and cataract instruments would, I verily believe, fill a column of *The Times* newspaper, and some of these inventors, I am uncharitable enough to think, would be well pleased to see such a list in print. There is, at all events, one satisfaction in all this: there is no scope left for any inventors in the future, and the mental energies of the succeeding race of practitioners cannot be better employed than in coming to a conclusion as to which is the best, or of sifting the wheat from the chaff, as far as all the different operations are concerned. All this diversity of opinion upon cataract operation can by careful analysis be reduced within certain limits. We may roughly arrange cataract operations into three principal divisions:—1. Operations without incision: displacement; solution or discission. 2. Operations with incision and laceration of capsule: flap; linear; median. 3. Operations with incision without lacerating the capsule: flap; linear. In the first class we may say that displacement is now obsolete, and discission is reserved for rare cases. The second class contains all those groups of operation which are usually performed for the extraction of senile cataract. The third class, containing the operation for the removal of the cataract within its capsule, is not much practised

Digitized by Google

in this country, although everyone must occasionally perform it. Within certain limits every surgeon should follow the method in which he feels confidence, or in which personal experience has given him peculiar facilities of execution. The performance of a cataract operation is to the surgeon what the execution of a difficult and intricate piece of music is to a musician. It looks simple, but it requires a certain amount of muscular and mental co-ordination. If the musician were frequently performing his difficult piece in one key, and were suddenly asked to play it in another, he would probably fail, or at all events would succeed indifferently. So a change in performing a cataract is usually at first attended with some indifferent success, and operators should not rashly change their mode of procedure unless they are sure that the change is for the better.

There are certain fundamental principles which should guide us in the choice of a cataract operation. 1. That the lens should have an easy and free delivery. 2. That the wound should be in a favourable place for apposition of its edges. 3. That the wound should lie in structures which best resist traumatic influences. 4. That the optical properties of the cornea should be as little interfered with as possible. 5. That no unnecessary mutilation should be practised upon the organ of vision.

Now, gentlemen, I have placed upon a diagram fourteen different plans of sections which have been adopted by various operators. (See illustration.) Time, I fear, will not allow me to enter at length upon all the points connected with them, but I will briefly examine their bearings as regards the principles I have laid down. We shall find that, as in other things so with cataract operations, we cannot attain

an ideal standard of perfection. Every operation violates one or more of these principles in a greater or less degree. The selection of an operation is a question of carefully balancing its advantages and disadvantages and applying it to the individual case upon which we are going to operate. A careful operator will therefore occasionally modify his procedure according to circumstances, and exercise a certain amount of eclecticism.

For nearly a century Daviel's operation was the classic operation for extraction. It occupied the inferior half of the corneal circumference and lay well within the cornea; it was subsequently modified by Beer, who removed the incision to the upper segment and brought it close to the sclero-corneal margin; as such it is now usually known as the "flap operation." Now, there can be no question that the merits of this operation are very great indeed. Personally I performed it for very many years after others had abandoned it. Ultimately I was induced to give it up; I did so with difficulty and regret; it was my first love, and, like all first loves, occupies a reverential place in my memory and my affections. Its merits are that it is easy of performance and can be done without an assistant—a matter in country practice of great importance. (An assistant who is not trained to a surgeon is worse than useless to him). It gives ample room for the escape of the lens, does not interfere with the pupil, and leaves an eye, when successfully performed, which leaves nothing to be desired as far as cosmetic conditions are concerned, and with regard to optical conditions may be said to be perfect. Now, what are its alleged disadvantages? Suppuration of the cornea, prolapse of the iris, loss of vitreous, iritis, tedious healing, and subsequent astigmatism from alterations of the curvature of the cornea. These accidents do occasionally occur after this operation; but, as you will see, they are dangers which are in a greater or less degree incident upon all cataract operations; and it is to obviate or minimise the one or the other that so many different operations have been introduced. Suppuration of the cornea is unquestionably the most prominent of its disadvantages. A large area of the cornea is cut off from its base of nutrition, and is apt in consequence to suppurate and necrose rapidly. Now, personally, I did not find this occurrence was so frequent as many other operators had done; it did not exceed 7 per cent. in close upon 400 cases. But on the Continent and in some of our large cities, where the constitutional conditions of patients are either below par or perverted by over-stimulation and excesses of all kind, no doubt the percentage would be much higher in the most skilful hands. Skill in operating has but little bearing upon the question; it is a question more of hygiene, both personal and as regards surroundings after the operation. The introduction of antiseptics into ophthalmic surgery—or perhaps I should rather say of the care and cleanliness which the antiseptic system necessitates—has done much to reduce the dangers of suppuration. Still there are risks in a large clinic over which it is absolutely impossible the surgeon can exert his immediate and constant control, and there always will be in this, as in other operations, a higher percentage of cases of failure in hospital than in private practice.

Another objection which with me was of considerable influence was the difficulty in some cases of keeping the flap in apposition. Occasionally the cornea was found thin or had lost its elasticity, and wrinkled easily. The movements of the lid would turn the flap back upon itself, and even after the most careful dressing this would sometimes occur, favouring suppuration and leading to hernia of the iris. Loss of vitreous is a complication which I think is a little more liable to occur, owing to the size of the wound and the consequent weakening of the support of the zonula. On the other hand, the free exit of the lens necessitates but little after-manipulation, which is not an infrequent cause of escape in some more modern operations. In properly selected cases I am still inclined to think that this operation is one which in its entirety is still deserving of a place. In France, which is the country of its birth, it still has staunch and able advocates. Holding these views, you may ask, Why have I abandoned it? When I commenced ophthalmic work fifteen or sixteen years ago, I had to practise at considerable disadvantages. The inconveniences and sanitary defects of our hospital were very great; we had no skilled nursing; and many of the patients could only remain a few days under our care, and had to journey long distances to their homes, where they often remained considerable periods without being seen. For patients so situated I came to the conclusion that flap extraction was not the best operation. I have still occasionally performed it in private cases, and now that I have a well-appointed and perfect hospital, with skilled nursing at my command, I should feel disposed to give it again a more extended trial in properly selected cases, but, as you will see by and bye, the latest development of peripheral extraction approaches so closely to it that I should have to do little more than change the knife with which I operate.

The feeling of dissatisfaction with the flap operation led

Digitized by Google

to the development of the so-called linear extraction. This operation, which originated with Messrs. Bowman and Critchett, was performed with a large triangular knife resembling a keratome, which was introduced perpendicularly with the sclero-corneal junction and pushed home. The base of the knife was large enough to make a wound through which, after the capsule had been lacerated, the lens could be extracted by means of a scoop or small spoon. In this way the formation of a flap was avoided and the dangers of suppuration much diminished, but the bruising of the iris and the frequent introduction of instruments into the anterior chamber were the cause of frequent iritis and irido-choroiditis. I will not dwell further upon this operation. I am not aware that anyone practises it in the present day except under special circumstances—for instance, in soft cataracts occurring in early life. Occasionally I make use of it under these circumstances, but instead of making the section upwards I generally make it on the nasal side of the cornea.

(To be concluded.)

A FURTHER CONTRIBUTION ON

CYCLIC ALBUMINURIA;

WITH OBSERVATIONS ON THE EFFECT OF VARIOUS CONDITIONS UPON THE DIURNAL APPEARANCE OF ALBUMEN.

BY F. W. PAVY, M.D., F.R.S.

I DREW attention at the Cardiff meeting of the British Medical Association to a form of albuminuria which occurs in persons otherwise presenting an appearance of being in a healthy state. Cases were narrated which showed that a diurnal variation of a more or less regular nature was to be noticed in the condition of the urine, and that what was observed one day was repeated with more or less closeness day after day for weeks, months, and even years. On account of the existence of this character I applied the term "cyclic" to the class of case under consideration, and in its vindication the following remarks may be offer ed. In reality, the term simply expresses a fact observed in connexion with the case. Necessarily there must be some determining cause for every round of events, whether it is apparent to us or not, and in the instance before us, whatever the explanation, whether from an influence arising within or operating from without, the fact stands that under the ordinary round of daily life a cyclic train of phenomena as regards the condition of the urine is observable. But there is a point of greater importance than the mere question of nomenclature, which is that the actual cyclic character susceptible of recognition may afford the means of distinguishing the class of case which is admittedly spoken of as "albuminuria in the apparently healthy" from the class falling within the category of albuminuria from Bright's disease. If subsequent experience should sustain the conclusion deducible at the present time, the distinction of the one class of case from the other is a matter of no inconsiderable importance in the interests of the public. To be regarded unnecessarily in the light of a person the subject of ordinary Bright's disease may entail a serious hardship through the effect exerted upon the future position in life. At the same time the uneasiness created in the minds of the relatives and friends must not be lost sight of. Looking at the number of cases that have come to light, and the incidental way in which the discovery has been made of the presence of albumen—for it does not usually start from the person himself being conscious of the existence of anything wrong,—it may be inferred that there is a large number of persons going about at the present time in the state in question without having a knowledge of it. Such being the position in which these cases stand, we, as members of the medical profession, incur a responsibility in determining the manner in which they should be viewed, and it behoves us, in justice to those who are guided by our precepts, to make ourselves fully and rightly informed with regard to them.

Concurrently with the insertion of my Cardiff communication in the columns of THE LANCET, a leading article was given upon the subject. Therein is cited the case of a young lady suffering from what was supposed to be "adolescent albuminuria," where it was observed that the urine passed shortly after rising was always highly albuminous. If she got up for breakfast, the urine, it is stated, was albuminous in the forenoon; if she got up after lunch, in the afternoon; and if after dinner, in the evening. Observations that I have recently made give a forcible significance to this remark, and apparently show that it has a wide bearing in connexion with the cases to which I am drawing attention. The following suitable case presenting itself, I noted the condition of the urine after (1) fasting till late in the forenoon, (2) remaining in bed till the middle of the day, and (3) taking a cold bath in the early morning and afterwards returning to bed.

E. M. B——, aged twenty, came to me in November last by the advice of Mr. Harcourt Coates of Salisbury. He belongs to a healthy family, presents a healthy appearance, and has not suffered from scarlatina. He has been engaged as a probationary clerk in the Bank of England for four years, during which time he has not missed more than ten days' attendance at the office from sickness, and this only at different periods in consequence simply of a "cold or biliousness." He did not know that anything wrong about him existed till he presented himself six months back for undergoing the medical examination to which the probationary clerks are subjected before being accepted for the permanent staff. The examination was conducted in May, and he was informed afterwards that he had not passed. He subsequently learnt that it was on account of his urine containing albumen that he had been rejected. Discordant opinions were afterwards given regarding his case by those who saw him, evidently due to the different periods of the day at which the urine was passed that was examined. When he underwent examination at the Bank, it was about 11 A.M. that the urine was passed for analysis. Investigation of the state of the urine, conducted upon several days, showed that in the early morning it was always entirely free from albumen, whilst at 10 A.M. and 11 A.M. albumen was to be found, sometimes in larger quantity than at others. Towards the latter part of the afternoon there was less, and almost invariably at bedtime it was again entirely free. The specific gravity was usually high, sometimes as high as 1034, and many specimens were turbid from a deposit of lithates. Microscopic examination revealed crystals of oxalate of lime, and upon some occasions uric acid. There were no casts or blood-corpuscles. The case being a marked one of cyclic albuminuria, and willingness having been expressed by the subject of it to try the effect of fasting, remaining in bed, and the employment of a cold sponge-bath, the following observations were conducted. In two of the three sets of observations it will be seen that no effect was witnessed, whilst in the other a decided influence was found to be exerted.

Fasting during the morning.—Dec. 9th: E. M. B—— got up at 7.30 A.M., and took nothing to eat or drink till 11 A.M., when he breakfasted. The urine passed at 7.30 A.M. presented the following characters: sp. gr. 1031; no albumen; acidity 7·947 per 1000; turbid from lithates. The urine passed at 11 A.M. (before breakfast) threw down, on testing, a decided precipitate of albumen. At 4 P.M. the quantity is recorded as a trace. On Dec. 12th the urine passed on rising between 7 A.M. and 8 A.M. was free from albumen. Nothing was taken till 12.30 P.M., and just before this time urine was voided. The specimen contained a moderate amount of albumen. At 4 P.M. the albumen had become reduced to a trace, and at bedtime there was none. Thus, with the absence of food, albumen showed itself as under ordinary circumstances.

Keeping in bed during the morning.—On Sunday, Dec. 6th, E. M. B—— kept in bed till 12.30 P.M., not rising even for passing the specimens of urine which were collected. Breakfast was taken at 8.30 A.M. Urine was passed at 8 A.M., 11 A.M., and at 12.30 P.M., the time of rising. All three specimens were free from albumen. At 2.30 P.M. there was no albumen, at 6 P.M. there was a questionable trace present, and at bedtime (11 P.M.) the record is a trace. On the following morning at rising it was, as usual, free. On the 13th the morning was passed in bed till 11 A.M. Urine was collected at 8.30 A.M. and again at 11 A.M. Both specimens were free from albumen. At 4 P.M. there was a faint trace, and at bedtime a decided amount present. Thus keeping in bed led to the urine remaining free from albumen throughout the morning. The appearance of albumen was thrown on till later in the day, and then only an insignificant amount was found in comparison with that ordinarily observed.

Digitized by Google

Cold bath in the early morning, and return into bed afterwards.—The object of this observation was to see if exposure of the surface to cold contributed to occasion the passage of albumen. For determining this point the bath required obviously to be employed under circumstances when albumen might not be expected otherwise to show itself. On Dec. 15th, E. M. B—— rose at 8 A.M., took a cold sponge bath, returned into bed, had breakfast, and remained in bed till 11 A.M. Urine was voided at 8 and 11 A.M., and both specimens were free from albumen. The urine passed at 4 P.M. contained a faint trace of albumen. That passed on going to bed was free, as was likewise that passed on rising the next morning, whilst the 11 A.M. specimen contained albumen as ordinarily observed. It was for the purpose of strengthening the information supplied that the examination of the urine was thus extended into the following day. On Dec. 17th the observation of the 15th was repeated, and I desired that the bath should be prolonged as far as convenient in order that a decided impression might be exerted upon the surface. The 8 A.M. urine was free from albumen. The 11 A.M. specimen gave a doubtful indication of the presence of the merest trace. The 4 P.M. specimen contained a faint trace, and that passed at bedtime a trace. On the following day the urine passed on rising was free, whilst that passed at 11.30 A.M. contained the usual amount for this period of the day under exposure to ordinary circumstances. The bath, therefore, did not produce any effect upon the urine. The condition observed was practically the same as after simply remaining in bed.

In two other cases I have obtained information, and it corresponds in nature regarding the influence of keeping in bed beyond the usual hour of rising. Both these cases were first seen by me some time ago, but I did not include them in my original communication, as I desired to have them under observation for a longer period before I made use of them.

Miss S. O—— was brought to me in February, 1885. She was then eleven years of age, and I was told that albumen had been noticed since the previous Whitsuntide. It was then looked for on account of a slight illness which there was some suspicion might be scarlatina, although there were no definite symptoms of it. The discovery of albumen, however, led to the conclusion, rightly or wrongly, that an attack of scarlatina had been passed through. When falling under my observation the case presented the characters of cyclic albuminuria, and has since continued to do so. In December last I wrote to the mother and asked her to keep her daughter in bed till the middle of the day, and to let me have specimens of urine sent for examination. It had been usual for albumen to become visible about 9 or 10 A.M.—Dec. 15th: The hour of rising was postponed till noon. The urine passed at this time was free from albumen. That passed at 9 P.M. contained a large quantity. The observation was repeated at the end of January, and upon this occasion specimens for the day prior were also sent to me.—Jan. 27th: The urine passed at 7.30 A.M. was free from albumen, whilst that passed at noon and also at 9.15 P.M. contained a notable amount.—Jan. 28th: The hour of rising was delayed till noon, breakfast, however, being taken as usual. Urine was collected at 8 A.M. and noon, and both specimens were free from albumen. The urine passed on going to bed at 9 P.M. contained a large amount.

The other case consisted of a boy whom I first saw in July, 1884; he was then thirteen years of age. The mother had been instructed in testing for albumen, and for some time the urine had been tested daily for days together at different periods of the day. The albuminous condition had been known to exist for two years. The mother told me that what she had generally noticed was that, whilst in the early part of the morning the urine was free from albumen, it contained a notable amount about 10 or 11 A.M., and that during the afternoon it usually disappeared. She regarded it as a bad day for the boy if the albumen did not disappear during the early part of the afternoon. At this time the condition excited grave apprehensions, and was watched with great anxiety from day to day, keeping both mother and son in a constant state of uneasiness, and acting in a decidedly prejudicial way upon the boy's progress in life. I advised that the testing should be abandoned and the boy dealt with as though he had something more than the prospect of an invalid life before him. I saw him in January, 1885, and then not again until the middle of December. It occurred to me at this visit to ask the mother if, when she was undertaking the daily examination of the urine, she had noticed any variation in relation to getting up and keeping in bed. She immediately replied that she had always noticed that the albumen did not appear till the boy had been on his feet for about an hour. These were the words she made use of, and the circumstance, she remarked, had struck her forcibly. As long as he remained in bed there was no albumen; and upon one occasion he was in bed for a fortnight with an attack of jaundice, and all this time the urine was quite free from albumen. Directly he got up it returned as before. She thought it strange, also, that when suffering from a cold, if she kept him in bed, there was no albumen. I had said nothing to prompt these remarks, and the evidence therefore may be accepted as strikingly corroborative of that otherwise obtained. Moreover, an explanatory idea had been framed in her mind upon the matter. It appeared to her, she said, as though getting up caused the albumen to filter from the kidney.

Taking it as accepted that there are certain cases of albuminuria of the kind that has been referred to standing distinct from those falling under the category of Bright's disease, the object presenting itself to be attained is to acquire information which will give us a full knowledge of their history and enable us to recognise them when they may happen to fall under view. The cyclic character noticeable in the condition of the urine under the ordinary round of daily life constitutes a valuable feature in the case from a diagnostic point of view; and the influence exerted by keeping in bed throws an important light, certainly from one aspect, upon the origin of the daily revolution observed.

Grosvenor-street, W.

ON THE

CAUSATION AND NATURE OF HYPERTROPHY OF THE PROSTATE.

BY REGINALD HARRISON, F.R.C.S.,
SURGEON TO THE LIVERPOOL ROYAL INFIRMARY, AND LECTURER ON CLINICAL SURGERY IN VICTORIA UNIVERSITY.

IN a paper recently published[1] on some Changes in Form of the Prostate and Floor of the Bladder I have shown that the inter-ureteral bar of muscular fibres so frequently met with in cases of enlarged prostate is to be regarded as the outcome of efforts, by the development of extraordinary agents of micturition, to expel urine from a part where it is apt to lodge and cause inconvenience. In connexion with these investigations, I have met with instances where an unusually depressed state of the floor of the bladder, or trigone, appeared to me to have existed previously to an enlarged prostate; in fact, that a condition of residual urine preceded, and was not the sequence of, enlargement of the gland. The trigone, or floor of the bladder, in addition to being a highly sensitive part, is peculiar in that it contains but few muscular fibres in its composition; muscle in abundance may be found as low as a line corresponding with the openings of the ureters, and marking the superior boundary of the trigone, and below in the prostate; between these two points the power of muscular contraction can hardly be said to exist. Assuming that, from any cause, such as long retention of urine, habit, position of the body, or the weakness connected with advancing years, the trigone, or non-contractile part of the bladder, becomes permanently depressed or altered in form, so that the person finds himself unable to get rid of the last half-ounce or so of urine, the effect will be frequently repeated expulsive efforts in all the muscles immediately adjacent to a part which, by reason of its connexions and structure, has no power of exercising contractility. This will eventually lead, as I have shown, to the hypertrophy of the muscular fibres between the orifices of the ureters—the inter-ureteral bar—as well as, I believe, to that of the muscular fibres so largely entering into the composition of the prostate. In this, I submit, will be found the immediate cause of prostatic hypertrophy. The change being an example of an hypertrophy, its production by conditions favouring the formation of over-growths observed in the body seems to be reasonable. Such a view, as applied to the large prostate, is strengthened by certain clinical observations. A frequent desire to empty the bladder is constantly met with in what is regarded as the earliest stage of

[1] Liverpool Medico-Chirurgical Journal, July, 1885.

Digitized by Google

prostatic hypertrophy, and long before the gland has assumed any considerable size; the more frequent the calls are to urinate, the more rapidly does the prostate grow, and all circumstances which tend to increase irritability of the bladder may be said to favour the development of this condition. Lastly, the only means which are known to have caused the opposite state—namely, that of atrophy, to be engrafted on the hypertrophied gland—are those which for a considerable time converted a muscular and physiological act into a purely mechanical one; for instance, the case I published[2] some years ago (since repeated with equally satisfactory results), where by the wearing of a cannula inserted through the perineum the process of micturition was reduced to the mechanical act of turning a tap on the part of the patient. Though regarding senile enlargement of the prostate as an hypertrophic change, I was at a loss to explain how it was induced until I met with instances where, from the conformation of the bladder, an irritating condition of residual urine seems to have preceded, and not to have been the consequence of, an enlarged prostate. Instances in practice are not uncommon in elderly males where all the symptoms usually assigned to prostatic enlargement are present, without there being evidence, beyond the presence of some residual urine, that any physical change in the gland has taken place.

I have frequently noticed that condition of unnatural contractility about the muscles connected with micturition, to which Sir James Paget's expression of "stammering with the urinary organs" may be applied, precede prostatic hypertrophy. I have a case under observation, where a locomotive engine-driver, aged fifty-three, has, owing it is believed, to the constant concussion connected with his occupation, been a stammerer of this kind. Rectal examination now shows that his prostate is commencing to enlarge, as not only is it increasing in breadth, but a distinct band of what I take to be muscular tissue is to be felt stretching across and filling it up. I was able to demonstrate this to my house-surgeon, Dr. Collins, and my clinical class, who had no doubt about the facts, whatever the construction placed on them might be. The sequence of events in this case appears to have been enforced retention by reason of the man's employment, incomplete emptying of the bladder, irregular and spasmodic efforts to expel residual urine, terminating in commencing hypertrophy of the muscles principally involved—namely, those associated with the expulsive action of the bladder. The frequency with which the floor of the gland is the first to show the hypertrophic change seems to strengthen the inference I have drawn from the development of the inter-ureteral bar, and to indicate that both conditions are the direct result of straining and an excess in the expulsive action of the bladder and associated parts. Structurally, the inter-ureteral bar and the hypertrophied prostate are identical, with the exception that in the latter will be found the follicles which have led to it being regarded as a glandular body. It is impossible to examine some of the commoner forms of advanced prostatic hypertrophy without being struck with their resemblance to what I would describe as growing casts of the interior of a frequently contracting bladder.

But it may be urged that if repeated expulsive action on the part of the bladder causes enlargement of the prostate to follow, how is it that stone and urethral stricture do not in like manner occasion it as a uniform consequence? To this I would reply that stone and stricture as excitants of expulsion are general or varying in their operations, and do not, as a rule, merely involve a limited area of the bladder wall; consequently the hypertrophy following stricture is universal so far as the viscus is concerned. In the same way, the whole bladder is involved when a growing prostate becomes in addition an obstacle to micturition. When a stone is fixed to the bladder, it is, I believe, subjected to precisely similar influences on the part of the bladder wall immediately adjacent to it as those described in connexion with the trigone, and may result, as I have seen, in a circumferential development of muscular tissue sufficient in some instances to produce sacculation. This is not an uncommon process, and may be studied with advantage in those cases where secondary calculi are developed as a consequence of surface irregularities produced by a large prostate, and which I have referred to elsewhere as fixed or stationary stones.[3] Further, it may be urged that such an explanation cannot be held to cover those instances where persons with more or less enlarged prostates do not suffer from them. I have investigated cases of this kind generally with the result of finding out that, at some period in their history, considerable urinary irritation was present and persistent. That an hypertrophy may prove to be *a precise compensation*, without, on the one hand, falling short, or, on the other, overlapping, I think we have evidence of here as in other parts of the body. It has been objected that enlargement of the prostate cannot be regarded as a mere muscular hypertrophy, as it does not occur during those periods of life which are most remarkable for muscular activity and development. On the other hand, it is hardly necessary to remark that, though an hypertrophic act in which muscular tissue is principally involved, it is really prompted by alterations in the form or function of a contiguous part which are the products of advancing years.

It may not be out of place to observe in connexion with analogous processes of hypertrophy, which in general terms have been referred to, that the best marked are those where structural defects are remedied, not in the part itself at fault, but in that which is adjacent. In the heart it is not the valve that is reproduced, but the ventricle or auricle which is augmented. Nor does the analogy cease here, for as the hypertrophied heart in turn occasions symptoms peculiar to itself, in like manner does the large prostate produce its own derangements. In conclusion, it should be remembered that the changes and diseases to which the hypertrophied gland is liable, and about which there is much to be said of great practical value, must not be confounded with the primary lesion it is desired here to refer to.

In addition to the valuable paper and plates by Sir Charles Bell, on the Muscles of the Ureters,[4] mention must be made of Mr. Viner Ellis's communication on the Muscular Arrangements of the Genito-urinary Apparatus.[5] In reference to the impossibility of dissociating the functions of the bladder and prostate, the latter author remarks: "I would propose the name 'orbicularis vel sphincter urethræ' for both the prostate and the prolongation around the membranous urethra; whilst I would confine the old term, 'prostate' (without the word 'gland') to the thickened and more powerful part near the neck of the bladder. This orbicularis may be considered as only an advanced portion of the circular layer of the bladder, though it must have the power of acting independently of the vesical fibres." The truth of this I never fully realised until I had practised, and watched the result of, a considerable number of operations, undertaken with the view of permanently relieving urgent symptoms attendant upon the large prostate.

THE EARLY TREATMENT OF RHEUMATOID ARTHRITIS.

BY JOHN KENT SPENDER, M.D. LOND.,
PHYSICIAN TO THE MINERAL WATER HOSPITAL, BATH.

EVERYONE who writes about rheumatoid arthritis is expected to begin with an apology for not calling it "osteo-arthritis," according to the precept of the College of Physicians. The apology is needed. An unscientific nomenclature condemns itself. An old writer says that "syllables govern the world";[1] and our conceptions of a scientific fact are governed by the terminology which represents it. A word or a phrase has teaching power, and moulds our belief even against our will. An old doctrine may have almost passed away; but the verbal symbol, if unchanged, recalls the doctrine, and the bond of logical association is too strong for us. Hence, as there are many reasons for rejecting the term "rheumatoid arthritis," there ought to be some potential reason for retaining it; and the fact is that no other term expresses with such graphic force a special group of clinical symptoms and anatomical changes. When fully developed no clinical picture is more easy to recognise; but the difficulty is to recognise it in the early stage when its outlines are only feebly marked. To study the evolution of a chronic disease is not a mere "pathological exercise,"

[4] Med. Chir. Trans., London, vol. lii. [5] Ibid., vol. xxi.
[1] Selden's Table Talk.

Digitized by Google

but is associated with the distinction and the success of therapeutic art.

I put, then, in the very foreground of my paper these postulates of chronic rheumatoid arthritis. Firstly, it is a disease which, though often springing out of ambush on a person in seemingly fair health, is an epilogue (or epiphenomenon) in the sense of being always preceded by a period of anæmia or defective nerve tone. Secondly, the natural tendency of the disease is almost always from bad to worse. Thirdly, the disease must be grappled with in the earliest possible stage if the medical battle is to be fought with any hope of victory. There is a point beyond which there is no hope of doing anything at all. Now, what can be predicated of a disease which bears these characters? One writer asserts that it is a nutritive disturbance of the joints peculiar to old age or premature old age, and that it is analogous to the atheromatous process which occurs in the internal tunic of the arteries at this time of life.[2] It is a sufficient answer to recall the fact that young people (even before puberty) are occasionally crippled by rheumatoid arthritis—people, I mean, whose youth is untinctured with the least trace of senility. The disease was considered by the late Dr. H. W. Fuller to be closely allied to struma, although he always called it by the misleading title "rheumatic gout." There can be no doubt that in a large number of cases there is a history of pulmonary or cerebral tubercle in the same family, or among kindred closely allied to the patient. Many high authorities might be quoted to the effect that the disease may come on as the treacherous sequel of repeated hæmorrhage (whether as menorrhagia or otherwise), of prolonged lactation or frequent childbearing, and especially of profuse leucorrhœa. Dr. Garrod says that excessive mental anxiety, and that kind of bodily fatigue which is the effect of night-watching, are potential elements in the etiology of rheumatoid arthritis. A note ought to be made of that curious pathological bias which associates nearly every form of chronic joint disease with something wrong in the nervous system. M. Charcot tells us that he has seen, coincident with nodular arthritis, certain nervous affections, such as shaking palsy and locomotor ataxy; but Trousseau remarks, with a touch of humour, that there is really no proof of any correlation in the pathogeny of these nerve diseases and nodular rheumatism.

Now, as a sort of bracket to bind together many stray phenomena, are we to forge a new thing and call it by the grand name of an "arthritic diathesis"? Fond and vain inventions are some of these so-called diatheses; spurious coin to hide the penury of genuine metal. As provisional schemes, or as stepping-stones to a wider pathological economy, a humoral or a neural diathesis has its value. Otherwise it is a mere empiric swing of the pendulum from blood to nerves, and then from nerves to blood again. But the phrase "arthritic diathesis," when rigorously examined, seems to mean this: Bone displays at different epochs of life a susceptibility to diathetic and enthetic influences, which renders it a delicate index of physiological vigour. If there be anything bad in the system, bone catches it up and tells the tale. Bones are not metaphysical abstractions, because they are out of sight; nor are they on a lower dynamic level than the soft tissues. Now, as the ends of bones are their *working* part, they are more exposed to the disintegrating forces which all work implies. Gout and rheumatism go to joints, not as such, but because they contain much of those structures which gout and rheumatism love to fasten upon. There may be plenty of rheumatism and gout in a body without any joint affection at all; but rheumatoid arthritis is a textural degeneration of joints *as such*, the outcome of wear and waste, though not the special property of any rank or age. That the degeneration is arthritic instead of being anything else does not make it a "diathesis," for any decay may spring out of some inherited or acquired weakness.

Is not our way now a little clearer? Is it not time to abandon utterly the untrue title "rheumatic gout"? Wherever this phrase is current, sounds of salicin and colchicum float in the air. In spite of discomfiture, again and again the routine and useless prescriptions are written, because salicin is "good for rheumatism," and colchicum is "good for gout."[3] The duty is done, and if the diseases will not obey the traditions, so much the worse for the diseases. Some natures are crushed by constant defeat, but others are roused to the necessity of better generalship, and ask, "Where does the therapeutic fault lie?" Is rheumatoid arthritis to be put in the same catalogue as cancer and all the other incurables? Verily not. It is a question of clinical insight and tact. Grapple with rheumatoid arthritis in its earliest manifestation; let us disengage ourselves from all scholastic theories of its origin and nature; and let our therapeutic aims be clear and easy to be carried out. It does not help us one morsel to repeat what Haygarth, Cruveilhier, and Heberden thought and taught in this matter. A procession of these honoured masters is the merest pageantry of old physic. They came, they saw, and in many things they conquered; they did wonders, but they could not conquer in everything; much seed which they flung about bore no fruit. We know more than they without being necessarily their betters; and if our finer therapeutic harvest does not enable us to do more good, so much the greater discredit to ourselves.

To cure a disease, or even to substantially relieve it, we must understand its beginnings and trace it from its germ. The earliest symptoms of rheumatoid arthritis are subtle, and easily confounded with other things. If rheumatism be uppermost in our minds, and if we see a great deal of it, we shall call all pains "rheumatic" which infest joints and muscles. Weakness and spanæmia are the natural allies and sequels of rheumatism; and if we hear a history (however remote) of rheumatic pyrexia, we shall probably conclude that our patient's aches and stiffness are only renewals of old troubles. Thus is the veil woven which blinds the clinical vision, and we ourselves are the artificers who weave it. How, then, are we to identify rheumatoid arthritis in its early simple phase, so that we may steal a march upon it and prevent its development? Putting aside for a while the academic distinctions of the acute, chronic, and irregular forms, we search for the ideal picture. A woman (rich or poor, it matters not) has gone through much childbearing, or has endured a long lactation and perhaps more leucorrhœa, or has been the victim of bodily privation and mental anxiety. One morning she awakes and feels a pain in her wrist; she thinks that she must have twisted or overworked it; she blames the weather or a hundred trivial things, and she winds up her random meditations by calling it "only a little rheumatism." Or there is pain in and among the carpal bones; there is effusion in the synovial sheath which surrounds and guards these bones; the hand looks thicker when held up and viewed sideways, and it cannot be easily opened and closed. Or there are tenderness and tightness in the palm, so that the hand involuntarily shuts when left to itself to relieve tension of the palmar fascia. Perhaps the lower limb suffers first, and the patient cries, "I have something wrong in the hollow of my foot; there is pain every time I bend the instep when walking up and down stairs." Next the ankle swells, and the difficulty of walking increases. An unwary doctor says that the ankle "has been sprained," and he may order cold douches with other very inappropriate remedies. But the supposed injury does not get well, and presently there is a puffiness around and above the malleoli, with an increasing lameness and weakness in the limb. Then, strange to say, instead of going straight to the knee, the disease may fly to an upper limb, crippling in rapid succession fingers, wrist, and elbow. Sometimes the fingers are swollen, reminding us of erythema or chilblain; and more often the first and second metacarpo-phalangeal articulations are early and severely affected. A very characteristic feature is the quick and obstinate flexion of the elbows; and now and then we see cases in which a shoulder or hip is the single joint involved and permanently injured. But there is a group, not numerically small, in which the ruin of joints is subordinate to an intense and cruel neuralgia, flitting about over nerve-threads and nerve-centres, murdering sleep, crushing the functions, creating a misery and a weakness which smother all the joy of life, and even overthrowing the intellectual and emotional faculties, so that the issue thereof may be insanity and suicide.[4]

It is quite true that the arthritis we are considering may

[2] Dr. Althaus: British Medical Journal, Sept. 28th, 1872.

[3] The term "rheumatic gout" may be appropriately given to certain hybrid forms of rheumatism and gout together, and to these only; they are not uncommon, and are not always easily diagnosed.

[4] A little monograph might be written on the early neural symptoms (not causes) of rheumatoid arthritis. Vaso-motor phenomena are quite common in the form of coldness or purple blushing of the skin. Sensorial aberrations are recognised in the various grades of dysæsthesia, from the feeling of numbness or "pins and needles" to severe aching and sudden pain. Muscular cramp or spasm is often complained of. The spinal phenomenon of shivering is now and then exactly synchronous with the earliest outward signs of rheumatoid arthritis. It is remarkable how little this subject has been examined.

Digitized by Google

be the sequel of an injury; such an injury, I mean, as may occur in the routine duties of domestic life, and be deemed hardly worthy, perhaps, of medical care. The accident is forgotten by lapse of time, but the weakened joint structures are more vulnerable to pathological storms. When disease comes, its effects may not be separable in outward guise from the injury which went before; and it must be remembered that a joint which has been once dislocated is an easy prey to rheumatoid arthritis. Then this disease so often follows rheumatic pyrexia that the one may seem only a postscript or appendix to the other; but this postscript is different in substance and in form, although its gross physical result is merely an increment of previous shock and damage. In our Mineral Water Hospital we see many mixed forms of this kind, in which true gout or true rheumatism began the sequence of morbid changes; and it has been only after years of privation and toil that the later degenerative changes have set in, ruining finally and completely those joints which were partially spoiled before. Another matter of interest is this: The joints which have been most actively engaged by the special craft of the patient, whether this be husbandry or carpentry, needlework or washing, are usually the first to show signs of arthritic deterioration. The complementary forces of hypertrophy and atrophy have been stirred; synovial secretion becomes muddy, cartilage is torn to shreds, bone is ground down to its primitive elements, and all because the mill so seldom stops; the mangle, the spade, and the needle go drudging on without that rest which is not less physiological than moral. Once more. The etiological alliances of rheumatoid arthritis are many and far-reaching. The disease may have for its companions nearly every form of degradation which can beset animal tissues. In the dulness of a clinical fog we sometimes drift about, and can get no further than a provisional guess of "arthritis"—a guess which almost anyone can make; and then it is that the textural behaviour of eyes, hair, skin, and teeth becomes a valuable landmark, and offers material for a safe diagnosis. Nor are the important viscera less worthy of attention than the dermal appendages. So that although the arthritic phenomena may appear mixed and intertwined beyond all unravelling, there are generally some salient features which proclaim that the "rheumatoid" type of disease is the dominating one, giving a case a distinctive name and determining our views of its prognosis and treatment.

I have tried to enumerate the various points which help us to identify a disease which for obstinacy and intensity has its analogues among the malignant nosologies. But even a so-called cancer has one comparatively benign aspect, which is this: if totally rooted out in a stage which has been called local, in so far that there is no apparent poisoning of the fluids of the body, there may be a positive end to it, and neither itself nor anything like itself may ever return. On the other hand, a disease which is multiple almost from the beginning, by reason of many bones and many joints, creeps and lurks about we hardly know where; if ousted from one ground of vantage, it retreats to another only a little further away: the cunning marches of a vegetable parasite are not more difficult to follow. Here, then, is our plea for early battle with a merciless enemy. Pure rheumatism and pure gout differ from that enemy profoundly in their susceptibility of control by therapeutic effort. Even when joints are badly injured by erratic gout and repeated rheumatismal attacks, there is a wide scope for recovery if bony ankylosis and adhesions among the soft structures have not gone beyond a certain degree. But a joint, big or small, wrecked by this rheumatoid disease, is the despair of medical art according to our present knowledge. It is very pitiable when the vertebræ are so mortared together that the trunk moves like a rigid machine, when the head cannot nod or turn to either side, and when the lower jaw is so nearly motionless that food cannot be properly received and masticated. And if, in addition, the lower limbs are crippled so that support and the power of locomotion are destroyed, the general health suffers from lack of exercise, and the nervous system is prostrated by the sense of incurable helplessness.[5]

(To be concluded.)

[5] I have a copy of Dr. Robert Adams' "Illustrations of Rheumatic Gout," published in 1857. There is a plate exhibiting the havoc made by the disease on a large flat bone like the scapula; and several plates depict the "cartilaginous and bony foreign bodies" in different joints. Compare an excellent account in Mr. Barwell's treatise on Diseases of the Joints; and there are plates in Mr. Quain's Clinical Lectures. Dr. Garrod's medical survey of the subject should also be studied in Reynolds' System of Medicine.

CASE OF

PELVIC ABSCESS IN AN UNUSUAL POSITION, SIMULATING SOFT FIBROID TUMOUR OF THE UTERUS.

BY A. H. N. LEWERS, M.D. LOND., M.R.C.P. LOND.,
ASSISTANT OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

E.M——, aged thirty-six, married, having had eight children and three miscarriages (all before the fourth child was born), was admitted into the London Hospital on June 23rd, 1885, complaining of a swelling in the abdomen and of a red discharge from the vagina. Her last labour (four weeks previously) was a quick one; she lost a good deal of blood after the child was born, but otherwise the labour was quite normal, and she seemed to recover as usual, getting up on the tenth day, without having had any pain, shivering, or feverishness since her confinement. On the tenth day, when she got up she noticed the swelling in the abdomen for the first time; it was then much smaller than it was on admission, but had gradually increased to its present size. On the day she got up she felt so weak that she was obliged to return to bed. When she moved, even in bed, she had a dragging pain in the hypogastrium, but she had no pain so long as she lay still. She had had a red discharge from the vagina ever since her confinement.

On admission, the patient was thin and anæmic. The abdomen was somewhat distended. A smooth, elastic swelling was felt rising up from the pelvis to the level of the umbilicus; it was not tender. The swelling was symmetrically situated with regard to the middle line. It was dull on percussion; laterally, beyond the limits of the swelling, the abdomen was resonant. Nothing could be heard on auscultation over the tumour. The patient was put under the influence of ether in order that the relations of the swelling might be the more thoroughly determined. Through the speculum the sanious discharge was seen to be issuing from the os externum. A catheter having been passed to make certain that the bladder was empty, a swelling was felt in front of the cervix depressing the anterior fornix. Bimanually, this swelling was found continuous with that already noted in the hypogastric region. The uterus was movable; every upward impulse given to the cervix moved the tumour with it. The body of the uterus could not be made out distinct from the tumour. It was thought that the latter extended rather further towards the left than to the right. The sound was not used on this occasion. The temperature was 101·4° on admission, and varied for some six weeks subsequently from 102° at night (on one occasion 103·5°) to 99° in the morning.

On July 13th Dr. John Williams very kindly saw the case with me, and was of opinion that, while the case was an obscure one, the probability lay in favour of the tumour being a soft fibroid. The sound was passed; it reached a depth of three inches and a half, and passed towards the right.

Aug. 13th.—The patient has been treated since the last note with ergot, at first by the mouth and afterwards hypodermically, without any alteration taking place in the size of the tumour. A catheter being passed into the bladder, it was found per vaginam that it would be impossible to puncture the tumour in that situation without puncturing the bladder. An aspirator needle was therefore put into the swelling in the middle line, about midway between the umbilicus and the pubes, and a pint of extremely offensive pus drawn off, the tumour entirely disappearing.

Five days afterwards the swelling was as large as at first; it was tapped again on Aug. 22nd, and 22 oz. of pus were drawn off similar in character to the last. After each tapping the abdomen was firmly bandaged.

29th.—The swelling has filled up again, and is, if anything, larger than ever. To-day an opening was made under antiseptic precautions into the swelling, the edges of the abscess wall stitched to the skin, and a large drainage-tube five inches long inserted.

From this time to Sept. 15th the patient went on without a bad symptom, the temperature only once reaching 100°. The wound was dressed about every other day, the cavity of the abscess being washed out at each dressing with iodine-water and some iodoform placed in the deep end of the drainage-tube before reinserting it. The discharge, which had at first been very offensive, became quite sweet. The abdomen was

Digitized by Google

firmly bandaged after each dressing, large pads of lint being placed on each side of the wound.

On Sept. 15th, at 9 A.M., the patient had a rigor lasting seven minutes, the temperature rising to 101°. She complained of pain in her limbs and sore-throat; the pulse was very small and frequent (148). There was no pain in the abdomen, and the wound was looking well. There was a slight erythematous rash on the chest and arms. In the absence of any other discoverable cause, it was thought that these symptoms were due to absorption of iodoform, which had been very freely introduced into the abscess cavity. The cavity was therefore washed out with carbolic lotion, and the iodoform and iodine-water omitted. The next day the temperature was normal, and all the symptoms had disappeared.

Nov. 9th.—The temperature has remained normal since last note. The drainage-tube (which has been shortened from time to time and replaced by narrower ones) was left off altogether to-day. Since Oct. 5th the patient has gained 11 lb. in weight; she feels and looks very well. On Nov. 4th the catamenia came on, and ceased to-day, no red discharge having previously taken place from the uterus for more than three months. The uterus is freely movable, the body of it being drawn to the left side. The sound passes two inches and a half. There is still a small sinus an inch and a half deep in the abdominal wall, but there is little or no discharge from it. A fine probe coated with nitrate of silver was passed into it.

Dec. 31st.—The patient has been a fortnight at Eastbourne. The sinus is the same length as before, but only admits a very fine probe. She says the last menstrual period lasted a fortnight, but otherwise she has been quite well, and has maintained her weight.

Remarks.—It will be seen that considerable doubt existed for some time as to the nature of the abdominal swelling. It might have been a case of super-fœtation, the swelling being explained by the presence of a second less advanced ovum in the uterus, or in one horn of a double uterus; and it was on this account that the sound was not used when the case was first seen. The tumour did not, however, harden under manipulation, nor were there any physical signs of the presence of a fœtus, and the size of the tumour remained stationary. Other conditions the possible existence of which had to be considered were: soft fibroid of the uterus, suppurating fibroid, ovarian cyst, pyo-salpinx, and suppurative perimetritis or parametritis. "Soft fibroid" was the diagnosis provisionally made, and in favour of it there was the close attachment of the tumour to the uterus, the two moving together when an impulse was given to either, and the increased length of the uterine cavity—three inches and a half. Even the aspiration and resulting disappearance of the tumour did not absolutely exclude fibroid, as it might have been a fibroid that had undergone suppuration. But the small size of the tumour when first noticed by the patient on the tenth day after delivery, and its increase in size from that time up to the twenty-eighth day, was against the tumour being a fibroid. A pyo-salpinx is not commonly so large as this swelling, and the woman having been recently confined, the probability was against pyo-salpinx, which, if single, diminishes the chance of pregnancy occurring, and if double, as it usually is when it exists at all, is an absolute bar to conception. The absence of acute pain at any time was strongly against the supposition that the tumour was a suppurating ovarian cyst, and equally against a suppurative perimetritis. On the whole, it seems most probable that the tumour was due to a parametritis in the connective tissue between the uterus and bladder, which went on to suppuration. It is certain that the lower half of the abscess was bounded below and behind by the anterior surface of the uterus, below and in front by the bladder. It should have been said that at the time when the abscess was drained the general cavity of the peritoneum, so far as could be ascertained, was not opened.

Wimpole-street, W.

ST. PETERSBURG MEDICAL SOCIETY.—The election by this Society of the following office-bearers for the year now commencing has recently taken place:—President: Dr. Sutugintsum. Vice-President: Dr. J. Gribovski. Secretaries: Drs. Rabinovich and Dembo. The Society has also conferred the distinction of its honorary membership on Prof. Hyrtl and Dr. Péan.

CASE OF SCARLET FEVER ARISING OUT OF THE LATE MILK EPIDEMIC IN MARYLEBONE;

WITH UNUSUAL SYMPTOMS.

BY JULIUS POLLOCK, M.D., F.R.C.P.

I HAVE lately seen three cases of scarlet fever due to the contaminated milk that was lately distributed in Marylebone, and one of them presented features so unusual that it may be worth recording.

On the 9th of last December I was asked to see a young lady, Miss A. B——, aged nine, who, it was said, had come out in a rash. On calling, I was told that the child had been taken unwell rather suddenly the day before, and had been sick. Upon examining the rash, I had no doubt that the disease was scarlet fever; indeed, it was quite a typical case, with the bright scarlet rash, the sore-throat, the tongue, the fever, and the rapid pulse, as described in books. The child did not appear to be very ill, and as the rash was well out and the throat affection mild, I gave a favourable prognosis as to the issue of the case. The patient was at once isolated in an upper room, and a skilled nurse from St. John's House obtained. There was much speculation as to the source of the disorder, and, as nothing was then known about the milk, it was put down to accidental contagion. I ordered a mixture containing some carbonate of ammonia and citrate of potash, and the child was put to bed and kept on suitable diet. Every means was used to prevent the spread of the fever to the other children, five in number. The case progressed very favourably, and on the 14th the rash was nearly gone and the child practically convalescent. The next day, after some previous indisposition, her elder sister, aged eleven, came out with a bright-red rash, sore-throat, &c., and joined Miss A. B—— in the isolated room. All went well with both the patients until Dec. 29th, when I found the glands on each side of Miss A. B——'s neck a good deal swollen, a temperature of 103°, pulse 112 (at 10 A.M.), and another rash beginning to come out about the ankles and wrists. Both the children had had a warm bath with carbolic soap the day before, and Miss A. B—— warm linseed-meal poultices to both sides of the neck. Next day, the 30th, the glands had much gone down and gave no further trouble, but the rash had largely developed itself, was out thickly upon both thighs and legs, and thinly scattered about the rest of the body, a few spots appearing on the face. It looked to me more like psoriasis than any other eruption I had seen, but without the silvery scale. There was no rash at all on the other child. On the 31st the rash was still more marked, and of a dark-red colour with rather a coppery hue. In the course of this afternoon symptoms of acute cystitis came on, with painful and frequent micturition, the urine being loaded with blood, but containing no more albumen than the blood would account for. The next day I had the advantage of a consultation with Dr. Gee, to whom, however, the rash was as strange as to me. It occurred to both of us that the eruption and the cystitis might be due in some way to the use of the carbolic soap. I ordered some citrate of potash besides the old mixture, and some extract of belladonna (a quarter of a grain) as a suppository twice a day. I may mention here that the cystitis went on for about a week or ten days, getting gradually better, and finally disappearing, leaving no untoward results. On Jan. 2nd the left leg was observed to be rather swollen about the calf, which was very tender. The rash was fainter, but well out. In a day or two the whole of the left leg was much swollen and very tender along the track of the vessels. On the 5th Mr. George Pollock saw the child with me, and we were agreed as to there being probably some thrombosis of the femoral vein. The leg was wrapped in wool and kept absolutely at rest. On Jan. 11th the leg was still much swollen, especially high up, and the rash was still quite visible, though the general health was very good. On Jan. 15th the leg was a good deal smaller. From this time the leg slowly diminished in size, and the patient rapidly gained health and strength. At present (Jan. 21st) the left leg is still somewhat larger than the right, and there are faint traces of the rash left. The general health is very good.

I have very little comment to make upon this somewhat curious case. It would be very interesting to know what

Digitized by Google

part (if any) the use of the carbolic soap played in producing the rash, and what relation the cystitis had to the scarlet fever or the carbolic soap. Was the block in the veins of the leg a part of the original disease, or in any way related to the second rash or the cystitis?

HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

SEAMEN'S HOSPITAL, GREENWICH.
SURGICAL CASES, WITH REMARKS.
(Under the care of Mr. TURNER.)

IN the following cases, all of which present some points of interest, two—namely, the varicose condition of the veins of the lower extremity, and the injury to the shoulder—are specially worthy of note. Obstruction to the return of blood through the inferior cava is a rare condition, and in most of the cases recorded has followed parturition and been rapidly fatal, there being a septic thrombosis of the vessel. Some disease of the liver (occasionally malignant), the presence of tumours, or even simple thrombosis, dependent possibly on constitutional disease, will cause it. The last is a very rare condition, and most of the cases which have lived beyond a year or two have been due to this cause, and it is probable that to some such state was due the blocking in this case. The superficial veins appear to have adapted themselves fully to the altered condition. Fracture of the scapula is not common, though there are several cases on record. Here the acromion would appear to have been broken, as well as the outer extremity of the clavicle. The acromion is the part of the clavicle most exposed to injury, and the part most frequently broken.

CASE 1. *Extensive Varix, probably due to blocking of the inferior Vena Cava.*—Patrick G——, aged thirty, a sailor, was admitted into the hospital with a recent chancre and amygdaloid glands. With the exception of ague he had had no previous illness. His bowels were habitually constipated, acting only once in from five to eight days; defecation was often accompanied by pain in the hypogastric region. He looked a well-nourished, muscular man. The veins of both lower extremities were dilated and varicose, more especially on the right side. Over the front of the abdomen all the veins were dilated, one being especially prominent and varicose, extending from the pubes to the upper part of the chest. The current of blood was upward in these veins. There was a very marked right varicocele and dilatation of the veins of the back, especially on the right side. Nothing abnormal was discovered in the heart or lungs, and there was no evidence of any tumour anywhere. The patient said the veins had been enlarged "as long as he could recollect," and that he remembered the large vein on the chest and abdomen since he was ten years old. He could not account for them in any way.

CASE 2. *Large Bursal Tumours.*—Henry G——, aged fifty-two, blind for the last twenty years, had made his living by letting lodgings. He had done all the scrubbing of the floors himself. He first noticed a swelling on his right knee seven years ago, and a second one formed in front of the left two years ago. Both swellings gradually increased in size; that in front of the right knee had been discharging matter for two years. On admission the patient was a healthy-looking man. From the front of the right leg, immediately below the patella, projected a hard rounded tumour eleven inches and a half in circumference. On its outer side was a sinus discharging thin pus. Over the left patella was a fibrous tumour rather more than two inches in diameter. The tumours were removed with antiseptic precautions, and the wounds healed by first intention, with no constitutional symptoms. The tumours consisted of fibrous tissue concentrically arranged round a small central cavity, and were evidently bursal in their origin.

CASE 3. *Old Fracture of Spine of Scapula and of Acromial end of Clavicle.*—Daniel C——, aged fifty-two, a sailor, was admitted into the hospital on June 24th, 1885. Three months previously he was knocked down by a heavy sea and became insensible. He soon recovered his consciousness, and his right shoulder was then found to be injured. The captain pulled at his arm and something "went in with a jerk." He had been unable to use the arm since. On admission, the outer end of the clavicle projected upwards, and could be felt lying on the acromion process of the scapula. Below and to the inner side of this was a small piece of movable bone—apparently the tip of the acromial end of the clavicle slightly enlarged by callus. Upon carrying the finger along the spine of the scapula, there was found a notch about two inches and a half internal to the tip of the acromion. On each side of the notch was a little irregular callus. The acromion process was tilted downwards, and its upper surface looked more backward than on the sound side. This displaced acromion limited outward rotation of the humerus, the great tuberosity coming into contact with it when this movement was attempted. The deltoid was wasted, and there was considerable impairment of the movements of the arm, owing probably to injury to the muscles, which from the man's account had been much bruised and hurt by the accident.

CASE 4. *Necrosis of Upper Jaw following Scurvy.*—James F——, sailor, aged fifty-one, suffered from scurvy in April, 1884. His gums were spongy and tender, and an Italian doctor removed some teeth and dead bone from his mouth. The necrosis gradually extended, and he came to this hospital in December. The greater part of the palatal process of the superior maxilla was exposed, the gums had receded, the teeth had fallen out, the breath was very foul, and the patient generally ill. There was a sinus just below the inner canthus leading down to exposed bone. On Dec. 18th the greater part of the hard palate on the affected side was removed by the mouth, also a portion of the anterior wall of the antrum. There still remained a large amount of exposed bone, which was fixed and immovable. He was much improved by the operation, and began to gain flesh and strength. On Jan. 16th, 1885, two more pieces of dead bone were removed by the mouth. The remainder of the exposed bone gradually became covered, the sinus by the inner canthus healed by April, and the man was discharged with little if any deformity. The opening in the mouth leading into the antrum had contracted so as hardly to admit the tip of the little finger. It should have been noted above that for some considerable time after his admission into the hospital he suffered from effusion into the knee-joints.

CASE 5.—*Abscess in the course of the Spermatic Cord, simulating Hernia.*—Arthur H——, aged three, was admitted on June 5th, 1885, with a tense, hard, non-fluctuating swelling in the inguinal region, not extending into the scrotum. There was no impulse on coughing. Both testes were present in the scrotum. The child was very restless, continually crying; any examination of the tumour apparently gave much pain. The mother had first noticed the swelling the day before admission, and the child was said to have vomited during the night; the bowels were confined; tongue slightly coated. Temperature between 101° and 102°. The child was carefully watched, but after admission there was nothing like sickness. Ice was applied to the swelling, which on June 9th (the fourth day) presented at one spot well-marked fluctuation. The bowels acted naturally on this day. On the following day (June 10th) the signs of abscess were well marked. A small incision was made with antiseptic precautions, and about half an ounce of laudable pus evacuated. The wound had quite healed two days afterwards, and the patient was discharged on June 13th. It was discovered after his admission that he had struck himself in the scrotum with a sharp stick about a fortnight previously, and that he had again injured himself by a fall the day before—i.e., on the day his mother first noticed the swelling. There was no trace of any injury of the scrotum.

Remarks by Mr. TURNER.—The cause of the blocking of the inferior vena cava in Case 1 could not be made out; nor could it be ascertained why the varicosity should be greater on the right side of the body than on the left. There was no enlargement of the spleen accompanying the ague; and but for chronic constipation and the syphilis he had only just acquired, the man seemed a healthy subject. He was examined most carefully on more than one occasion, but no

Digitized by Google

evidence of tumour or swelling could be detected. Case 2 is of interest only on account of the size of the tumours, and that they occurred in a man from the usual cause—kneeling. Case 3 is an illustration of a somewhat rare injury—fracture of the spine of the scapula. The acromion process had been tilted to such an extent as to seriously interfere with the rotation of the humerus. Such a small piece had been broken off the acromial end of the clavicle that the upward displacement of the inner fragment resembled a dislocation of the acromio-clavicular joint. Case 4 shows how little deformity may follow necrosis of the upper jaw, provided the dead bone be removed or come away by the mouth. In Case 5 the inguinal swelling closely resembled a hernia, and but for the absence of vomiting might easily have been mistaken for it. The history given was very confused and untrustworthy.

KIMBERLEY HOSPITAL, CAPE COLONY.

SUCCESSFUL LIGATURE OF COMMON ILIAC ARTERY FOR ANEURYSM OF EXTERNAL ILIAC; REMARKS.

(Under the care of Mr. L. S. JAMESON, Senior Consulting Surgeon.)

Mrs. M——, aged twenty-eight, a thin Dutchwoman, was admitted on April 20th, 1885. Eleven months ago she first noticed a small swelling, the size of a nut, in the right groin. This gradually enlarged during the next six months to the size of an apple, occasioning no pain. The patient then felt a "beating" sensation in the swelling, with pain and numbness down the leg, the tumour enlarging more rapidly and becoming much softer. No specific history.

On admission she was a spare woman, all of whose organs were fairly healthy. Immediately above Poupart's ligament there was an oval swelling about the size of the head of a new-born child, with marked pulsation, extending outwards to within half an inch from the iliac spine, inwards to the middle line, and upwards to the level of the umbilicus. On deep pressure the tumour appeared still larger. The upper portion of the tumour was solid; the lower portion soft and of a deep purple colour, appearing as if the slightest pressure would rupture the skin. There was marked swelling of the whole of the right limb; no œdema; practically imperceptible pulsation in the posterior tibial artery. Morphia was given frequently during the next twenty-four hours, to relieve pain, until the consent of the patient and her friends to an operation could be obtained.

April 21st.—The bowels having been thoroughly opened by a large enema, chloroform followed by ether was administered. From the extent of the tumour it seemed impossible to expose the common iliac artery by operating on the right side; so Mr. Jameson determined to make the incision on the opposite side, afterwards crossing over the pelvis to the right common iliac artery. A curved incision was made on the left side of the abdomen from an inch above the level of the umbilicus to within an inch and a half of the middle of Poupart's ligament. The transversalis fascia having been divided to full extent of incision on a director, the peritoneum was stripped up with the fingers from the iliac fossa forwards and inwards till the left common iliac was exposed. This was followed up to the aorta and then down the common iliac, the latter being well overlapped by the tumour, the aneurysm evidently springing from the external iliac lower down. A previously prepared stout carbolised silk ligature was then placed about the middle part of the common iliac; all pulsation in the aneurysm at once ceased on the application of the ligature. Some slight hæmorrhage from a small vessel in front of the sacrum was checked by pressure of the finger for a couple of minutes without the necessity of using ligature. The external wound was then closed by deep and superficial sutures, and dry dressing applied. The pulse was fair on recovery from the anæsthetic. The patient was placed on her right side to permit the leg to remain horizontal, as the hip-joint was considerably contracted by the tumour. The limb was wrapped in cotton-wool and surrounded by hot bottles placed at a moderate distance. No stimulants were given, and milk was taken in small quantities, one-third of a grain of morphia being administered hypodermically every four hours.

22nd.—Morning temperature 101°; evening temperature 101·6°. Slight pain and restlessness. Morphia increased to five minims (one grain equal twelve minims) every four hours. No return of pulsation, but the wound is a little more discoloured in its lower part.

23rd.—Morning temperature 100·8°; evening temperature 101·4°. Slight oozing of bloody serum from the lower part of the wound. Morphia increased to one-third of a grain every three hours. Pulse 120, weak. No distension of the abdomen during the night; one liquid motion.

24th.—Morning temperature 100·6°. Had several hours' sleep; no pain. Brand's essence of beef added to milk diet, also to have three ounces of brandy in the twenty-four hours. Slight bloody serum still oozing from wound. Dry boracic lint changed twice a day. During the next three days no change worthy of note.

28th.—Temperature 99·2°. No pain; deep and superficial stitches removed. A moderate discharge of bloody serum. Gaping of the external parts at the lower end and in the middle of the wound. Evidently deep union throughout.

29th.—Temperature normal. Pain in the leg. Morphia reduced to half a grain every six hours.

May 1st.—Remaining superficial stitches removed; free discharge of healthy pus. From this period the external wound rapidly healed, also a large bed-sore over the sacrum, the size of the palm of the hand, from which she was suffering on admission. Patient remained in hospital three months longer, the tumour diminishing slowly in size.

Oct. 15th.—Dimensions of tumour on deep pressure were still two inches and a half by three inches, but quite solid. Both knee and hip-joints were considerably contracted, but the patient was able to get about with some difficulty. Otherwise she was in perfect health.

Remarks by Mr. JAMESON.—The great difficulty of the operation appeared to be at first sight to get at the artery at all from the extent of the tumour, but as no other treatment, such as compression of the aorta, seemed to give any chance of success, and as the aneurysm must prove fatal by rupture within a few days at the most, it was determined to attempt it. It was only when the patient was on the table under anæsthesia that considering it impossible to get at the artery from the same side Mr. Jameson determined on operation from the other side, though without any data of such an expedient having been adopted before. However, in this case necessity and success must justify what would otherwise have appeared foolhardy.

ANEURYSM OF THE AORTA SIMULATING ANEURYSM OF THE INNOMINATE TREATED BY SIMULTANEOUS LIGATURE OF THE COMMON CAROTID AND SUBCLAVIAN; REMARKS.

Samuel M——, aged fifty-nine, was admitted under the care of Mr. Jameson with a pulsating tumour the size of an orange at the lower part of the neck on the right side, extending upwards to the lower border of the thyroid cartilage, outwards to the junction of the outer and middle third of the clavicle, and inwards a quarter of an inch beyond the middle line. The sternal end of the right clavicle was about half an inch more prominent than the left. A faint systolic bruit was heard all over the tumour. The patient complained of continuous agonising pain in the right arm and right side of the chest. There was extensive bronchitis, and he could only sleep in a sitting posture.

Mr. Jameson ligatured the right common carotid and right subclavian arteries. The day after the operation there was no pain. Both wounds healed by first intention. Temperature normal throughout. The tumour became harder and pulsation diminished during the next two months; after that pain in the left arm came on. At this time Mr. Jameson was compelled to leave Kimberley, and on his return, six weeks later, Dr. Wolffe, the resident surgeon, informed him that the patient had died a week previously; and at the post-mortem examination he had found that the aneurysm had existed in the commencement of the arch of the aorta; that there was a thick fibrous laminated wall on the right side; and that to the left there was an enormous thin-walled sac which had eroded the spinal column pretty deeply.

Remarks.—There can be no doubt that a partial cure was effected by the operation, and certainly it enabled the patient to enjoy three months of comparative health free from pain. No antiseptics, further than strict cleanliness and boracic lint dressings, were used in either of the foregoing cases. When Mr. Jameson first went out to Cape Colony, seven years ago, he asked Mr. John Marshall as to the advisability of providing himself with the parapher-

Digitized by Google

nalia for strict antiseptics. He remarked: "You are going to an antiseptic climate, and don't require them." This opinion had since been fully justified. Going there direct from some years' residence in a large London hospital, the difference, Mr. Jameson states, was astonishing; grave injuries, such as compound fractures of the limbs, where amputation would appear imperative, healing in a marvellously short time under some simple dressing, such as wet boracic lint.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Annual General Meeting.—President's Address.

THE annual general meeting of this Society was held on Monday last, Dr. George Johnson, F.R.S., President, in the chair.

The report of the Council was read by the hon. secretary, Mr. Howard Marsh. Thirty new Fellows have been elected, and twenty-one Fellows have been lost by death. The total number of Fellows is now 736. The report of the hon. librarians states that the additions to the library during the year 1885 consist of 422 works. The number of volumes in the library is about 36,000. During the past year the Society's collection of portraits of members of the medical profession has been enriched by the addition of sixty-three new portraits. The adoption of the report was proposed by Dr. C. West, seconded by Mr. R. W. Parker, and carried.

The President then read his address, which contained very interesting matter. Speaking of Henle, by whose death the Society had lost one of its foreign honorary Fellows, Dr. Johnson said that one of the most interesting and important of Henle's anatomical discoveries was that of the muscularity of the middle coat of the arteries, which he clearly described and figured in his "Allgemeine Anatomie," 1841, p. 498, plate iii., figs. 8, 9, and 10. This discovery formed the anatomical basis for the experiments and conclusions of Brown-Séquard and Bernard, which led to our present knowledge of the regulating function of the muscular arterioles and of the vaso-motor nerves. And assuredly until this knowledge had been acquired we were but imperfectly acquainted with the forces which are concerned in effecting and regulating the circulation of the blood. It has now been proved to demonstration that the muscular force possessed by these Lilliputian canals is so great that the united forcible contraction of the pulmonary or of the systemic arterioles is more than equal to the propulsive power of the corresponding right and left ventricles of the heart, and in consequence the onward movement of the blood may be thereby arrested. This arrest of the circulation by the contraction of the muscular arterioles is most easily demonstrated in the lungs. Physiologists all agree in teaching that the function of the arterioles is to regulate the blood-supply to the tissues, and to exert, in short, what he had ventured to call a "stopcock" action upon the blood-stream. In reply to Dr. Goodhart's objection to the "stopcock" theory that there is no such antagonism in nature as it would imply, he said he need only refer to the notorious fact that muscular antagonism in the case of both voluntary and involuntary muscle, with resulting physiological harmony, is of constant occurrence. Referring to the discussion on cholera, Dr. Johnson said that if it did not increase our knowledge, it served to bring into view the very contradictory opinions which are held, not only with regard to the etiology, the infectiousness, the pathology, and the treatment of the disease, but also with reference to such easily and often demonstrated anatomical facts as to the relative amount of blood in the two sides of the heart during the stage of collapse when the chest is opened soon after death.—A vote of thanks was proposed by Dr. Grailly Hewitt, and seconded by Dr. Symes Thompson, for the President's address. The vote of thanks to the retiring members of Council was proposed by Dr. Althaus, seconded by Dr. B. O'Connor, and acknowledged by Dr. C. T. Williams. The vote of thanks to the retiring secretary, Dr. Douglas Powell, was moved by Dr. Church, seconded by Dr. Buzzard, and carried with acclamation. The President declared that the result of the ballot was the unanimous election of the gentlemen nominated by the Council, and published in THE LANCET last week.

PATHOLOGICAL SOCIETY OF LONDON.

Congenital Cystic Kidney. — Pistol-shot Wound of Cranium.—Villous Tumour of Accessory Thyroid.—Cancer of Thyroid in Myxœdema. — Ossifying Sarcoma of Radius.—Aneurysm of Septum Ventriculorum.—Congenital Skin-tumour of Sigmoid Flexure.

Dr. J. S. BRISTOWE, F.R.S., President, was in the chair at the ordinary meeting of this Society, held on Tuesday last.

Mr. SHATTOCK read a paper on Bilateral Cystic Disease of the Kidneys in the New-born. The specimen shown proved beyond all doubt that the cysts are retention-cysts, since all transitions were traceable from long dilated passages to the more definitely circumscribed cysts; and the smaller cysts, as well as the dilatations, were lined with similar well-formed cubical epithelium. It was possible that the cystic disease might arise from a histological mal-development of the kidney, and that the spaces were retention-cysts originating in the tubules of the mesonephros or Wolffian body. The frequent association of other malformations with congenital cystic disease of the kidney, pointed out by Virchow, was worthy of remembrance in this regard. In the specimen shown there were no other abnormalities; the ureter was normal and pervious, as also the renal pelvis and calyces. The kidney was smooth externally, presented traces of lobulation, and the capsule could easily be separated. The organ measured three inches long and two inches broad. Since the discovery of widely distributed remains of the Wolffian body in the ovarian stroma, increasing interest has attached to cystic ovarian disease; similar remains of Wolffian bodies were to be found in the testicle. The metanephros, which forms the permanent kidney, is only a specially differentiated posterior portion of the primitive mesonephros or Wolffian body. Adopting Kölliker's view that the renal tissue is formed by tubular extension from the branching upper end of the ureter, it may be conceived that the congenital cystic kidney results from a want of differentiation of the metanephric blastema from that of the mesonephros or Wolffian body. The existence of two or three ureters could be understood embryologically when we remembered that in the mesonephros of the amphibia there were as many ureters as there were segments of the mesonephric kidney.—Dr. NORMAN MOORE considered that if the glomeruli were normal, the cystic disease was most probably congenital, and not due to interstitial nephritis.—Mr. J. B. SUTTON had seen examples of congenital cystic disease of the kidneys in many mammals. He had detected frequently the remains of the mesonephros in the ovary and testicle. The anterior end of the kidney of teleostean fishes was admitted to be of mesonephric origin.—Dr. QUARRY SILCOCK referred to the large amount of well-formed fibrous tissue in Mr. Shattock's specimen. He had seen cases of cystic disease of the kidneys associated with cysts in the liver.—Mr. SHATTOCK replied that the arteries were healthy in his specimen. Klein had figured cells in the stroma of the human kidney, indistinguishable from those lining the tubules, and so mesonephric remains in the kidney might be ound to be not unfrequent. Congenital cysts differed from all those acquired after birth, both in their mode of origin and anatomical characters. The fibrosis he explained as secondary to the tension exercised by distension of the cysts in the manner that cirrhosis of the liver ensued after experimental ligature of the bile duct.

Mr. C. B. LOCKWOOD exhibited a specimen to show the effects of a Pistol-shot Wound of the Brain. It was a case of attempted suicide; the bullet passed through the hard palate, orbit, ethmoid, and frontal part of the brain, and made its exit in front of the coronal suture. There were signs of intra-cranial inflammation. At the end of twenty days an abscess developed, was opened, and the bullet with some bony débris removed. The bullet had not entered the lateral ventricles. There were no signs of meningitis. The patient lived one month after the receipt of the injury, and died from septic poisoning. Stupor was the chief symptom, though he could be roused and could remember recent events. In reply to Mr. Marmaduke Sheild, Mr. Lockwood said that it was not certain until the abscess was opened whether the bullet lay beneath the scalp or within the skull. The aperture of exit in the calvaria was larger than that of entry.

Mr. BILTON POLLARD showed a Tumour which he considered had been developed in an accessory Thyroid Gland

Digitized by Google

When first noticed the growth was about the size of a pea, and was situate in the right anterior triangle, about two inches from the middle line at the level of the upper border of the thyroid cartilage. The tumour grew gradually, and attained the size of a hen's egg in a year and eight months; during the next four months it grew rapidly, and when the patient was admitted to University College Hospital it nearly filled the right anterior triangle of the neck. It was freely movable, but did not alter in position during deglutition. It was so deeply placed that during its removal it was found necessary to excise along with it the middle third of the scalenus anticus muscle and two inches of the internal jugular vein. Two enlarged glands were removed from the lower part of the posterior triangle, but they were not examined microscopically. The tumour consisted, in the main, of a cyst about the size of an orange; it was lined with a smooth membrane, and into its interior several villous growths projected. The solid portion of the growth was divided by fibrous septa into compartments, which were closely packed with a granular substance, which microscopical examination proved to be composed of delicate villous processes lined with short columnar epithelial cells. In some parts the growth was composed of small spaces and tubes lined with cubical epithelium and filled with a colloid substance, The structure of this portion bore close resemblance to that of the thyroid gland. The origin of the tumour was open to doubt, but Mr. Pollard thought its appearances were fully explained by supposing that it grew from an accessory thyroid gland, that cysts had first been formed, and that subsequently they had become filled with delicate papillary growths. In reply to the President, Mr. Pollard said that the growth was of benign character and had not infiltrated, though it was adherent to the scalenus anticus muscle.—Dr. NORMAN MOORE had seen a villous growth in a large cyst of the thyroid gland. Accessory thyroids were very rare. If there were a new growth in an accessory gland he would expect the thyroid itself to be enlarged.—Mr. J. B. SUTTON considered that the tumour might have developed about the lower end of the thyroid canal, and said that a German author had described accessory thyroids in a situation which would correspond to this.—Mr. POLLARD said there was no perceptible enlargement of the thyroid body.

Dr. GULLIVER showed a specimen of Cancer of the Thyroid Gland associated with the symptoms of Myxœdema. It came from a woman aged forty-four. The cancer had grown round the trachea and compressed the œsophagus slightly. On the right side the sterno-thyroid muscle was adherent and infiltrated, and the lymphatic glands on this side were much enlarged. During life there were all the features of myxœdema of four years' duration. There was some stridor towards the end, but no dysphagia, and the patient died from asthenia. The specimen was interesting and rare; such a combination of disease had hitherto not been recorded. Myxœdema had been seen in association with tubercle. The partiality that cancer had for atrophied organs or for organs whose functional activity had ceased was illustrated by this specimen. In a case of Mr. Shattock's of sporadic cretinism (patient aged thirteen) the thyroid gland also showed a typical form of cancer, which was of course of more recent date than the atrophy of the organ.—Dr. HADDEN asked whether Dr. Gulliver regarded the cancer as in any way causative of the myxœdema. In thirty fatal cases of myxœdema of which he had notes no cancer had been found. In myxœdema the thyroid showed interstitial changes together with proliferation of the epithelial cells.—In reply, Dr. GULLIVER said he regarded the cancer as an epi-phenomenon.

Mr. BERNARD PITTS read notes of a case of Ossifying Sarcoma that occurred in a young man aged twenty-one, who was first seen on June 24th, 1885, with a swelling of the right wrist, over which the skin was reddened, hot, and tender, but the joint was not involved. There was a history of a sprain two years previously. Iodide of potassium led to no improvement. A large gland developed at the bend of the elbow. On July 14th an operation was performed, when new bone was found about the wrist and regarded as of inflammatory origin. Later on, a pedunculated exostosis appeared at the upper part of the left fibula and another below the right great trochanter. At the site of the wound there developed a large nodulated mass, which extended from the wrist upwards. On August 26th pleuritic effusion had developed, and death took place on September 29th. At the necropsy the left pleura was found to be infiltrated with the ossifying sarcoma, and formed an almost perfect cast of the thorax on that side. The growth infiltrated many parts of the lung, and could be traced distinctly along the branches of the pulmonary artery. The primary and secondary growths were composed of large round cells bounded by alveolar walls, which were calcified. The primary growth was a sub-periosteal ossifying sarcoma. A point of interest was the entire absence of soft structure in the line of operation and the consequent mistake in the early diagnosis. The lymphatic glands were directly infected, being very much ossified.

Dr. FREDERICK TAYLOR showed an Aneurysm of the Septum Ventriculorum, which came from a man aged fifty-five, who died from cerebral hæmorrhage. The aneurysm developed at the site of the undefended space; it was a globular sac, with an opening of triangular shape, measuring half an inch by five-eighths of an inch; the sac was about five-eighths of an inch in depth. It bulged into the right auricle and right ventricle. There was no evidence of endocarditis, and this absence, with the smooth character and site of the aneurysm, led him to regard the specimen as of congenital origin. A soft systolic murmur was heard at the apex during life. Another similar specimen, dating from 1858, was also shown from the museum of Guy's Hospital.—Mr. STANLEY BOYD exhibited a specimen in which there had been endocarditis of some duration; there was an aneurysm projecting from the right side of the aortic cusp beneath the left coronary artery; it was divided by a septum. —Dr. ANGEL MONEY related the case of an idiotic girl, aged seven, who had pyrexia and a systolic murmur, which was loudest over the septum. There was an aneurysm of the undefended space that opened up the layers of the septal cusp of the tricuspid valve. All the cardiac valves were in a peculiarly "pouched" condition, probably due to syphilis, and there was a large gumma in the brain.—Dr. PERCY KIDD referred to specimens of aneurysm of this region which he had exhibited last session; one occurred on the posterior aspect of the undefended space, and was an aneurysm due to endocarditis; this was a very rare condition.—Dr. S. COUPLAND referred to a remarkable specimen deposited in the Middlesex Hospital Museum. It came from a man aged twenty-four: there was a cavity in the septum ventriculorum, and the two ventricles communicated through it; it was situate below the undefended space, and each orifice was small as compared with the cavity which lay between them, which was lined by very tough membrane; one orifice was surrounded by tough vegetations. Probably a laceration of muscular fibres had taken place as the result of hæmorrhage, and the aneurysm had eventually burst into both ventricles. The specimen was almost unique.

Mr. CLUTTON showed for Dr. Floyer a specimen of Congenital Cutaneous Polypus, which had been removed from the sigmoid flexure. The patient, a girl of eight or nine years of age, was taken suddenly ill in October, 1884, with pain, rigors, high temperature, and diarrhœa, and in the course of three weeks passed a large quantity of very offensive matter and blood, and in another week after this discharge a tress of hair of considerable size was removed from the anus. The acute symptoms subsided in four or five weeks, but she still continued to suffer from very distressing symptoms of tenesmus, which had been a source of great discomfort throughout her illness. About Easter, 1885, a tumour was noticed, during these attacks of tenesmus, to protrude at the anus, and was returned as often as it appeared, with relief to the patient's symptoms. In August, 1885, she came under the care of Dr. Floyer, who, whilst treating her for chronic constipation, found, on examination of the abdomen, a swelling in the left iliac fossa. Shortly after this, in examining the rectum, Dr. Floyer thought he felt a polypus attached by a double pedicle to the mucous membrane at a considerable distance from the anus. Mr. Clutton was then asked to see the case. Under chloroform it was easily demonstrated that the tumour in the iliac fossa was the polypus, which could in efforts of straining be forced down into the rectum. The pedicles were tied with silk, and the tumour removed. The specimen exhibited to the Society was shown to possess a perfect cutaneous envelope covered with fine short hairs. At a spot near the pedicles there was a bald shining patch, with a sinus in its centre, which was thought to have been the seat of the abscess described in the history of the illness in October, 1884. A long tress of hair was also shown, which was believed to have been attached to the tumour over the surface of this abscess. The central parts of the polypus were composed of fat and fibrous tissue with a little

Digitized by Google

bone. Allusion was made to a similar case recorded by Dr. Port in the Pathological Society's Transactions, vol. xxxi., the only difference being in the exact seat of the growth in the two cases. Dr. Port's specimen was removed from the mucous membrane of the rectum, at about two inches and a half from the anus; whereas in the case now recorded there was evidence to show that it was seated at the juncture of the sigmoid flexure with the rectum.—Dr. FLOYER regarded the lump, which was still present in the iliac fossa, as the remains of the pedicle.—Dr. CHARLEWOOD TURNER suggested that an ovarian tumour might have penetrated the sigmoid flexure and become inverted there.—Mr. J. B. SUTTON believed that the tumour originated about the neurenteric canal, and was an example of a very rare tumour. In reply to Mr. Boyd, he said the epiblast at the anus only invaginated for about half an inch to three-quarters of an inch.—Mr. CLUTTON felt sure that the residual lump was the remains of the pedicle, and said that the centre of the tumour contained bone.

The following card specimens were exhibited:—Dr. Payne for Dr. Jacob of Leeds: Tumour of Finger. Mr. Pollard: Dermoid Cyst of Testicle. Dr. Lediard of Carlisle: (1) Senile Ovarian Blood-cyst; (2) Hernia Reduced *en masse;* (3) Cancer of Rectum—Excision; (4) Cancer of Œsophagus—Gastrostomy. Dr. Turner: Hepatic Cells in Blood of Portal Vein. Dr. Carrington: Mitral and Tricuspid Stenosis. Mr. E. H. Fenwick: (1) Fibro-sarcomatous Polypi from Bladder; (2) Papilloma of Bladder. Mr. Makins: (1) Diastasis of Cervical Spine; (2) Carcinoma of both Superior Maxillæ. Dr. Drewitt: Heart and Pericardium from a case of Rheumatic Nodules. Mr. Lunn and Mr. Larder: Aortic Aneurysm.

CLINICAL SOCIETY OF LONDON.

Traumatic Inguinal Aneurysm; Rupture of Sac; Ligature of Arteries.—Aneurysm occurring in Stump.—Intussusception of Upper Part of Jejunum.—Acute Intestinal Obstruction with Acute Peritonitis; Abdominal Section; Rapid Recovery.

AN ordinary meeting of this Society was held on the 26th ult., Mr. Thomas Bryant, F.R.C.S., in the chair.

Mr. C. MANSELL MOULLIN read a paper on a case of Traumatic Inguinal Aneurysm; Rupture of Sac; Ligature of the Common Femoral and External Iliac Arteries. The patient, a man aged thirty-four, had received a severe blow in the groin from the edge of a flat piece of iron about four weeks before admission. There was a good deal of swelling and discolouration about the part for some days. Three weeks after receiving the blow the swelling reappeared, and continued to increase in size until the morning of admission, when, during an effort, he was seized with violent pain, and a large pulsating tumour made its appearance in the groin, extending into the scrotum and perineum. The foot and leg were not much swollen, but the skin in the groin was red and œdematous, and the scrotum much discoloured. An incision was made into the swelling over the femoral artery (after an abdominal tourniquet had been applied), and a longitudinal slit found in the wall of the vessel, immediately under Poupart's ligament. A director was passed down it, the artery separated and tied below the injured part with catgut. A fresh incision was then made above Poupart's ligament, for the purpose of securing the external iliac above the rupture. No other vessel was tied. The blood-clot, some of which was old and very adherent, some quite recent, was turned out as far as possible, a large drainage-tube inserted, and the limb carefully wrapped up in cotton-wool. The subsequent course was perfectly simple, except that the wound suppurated freely, and, until a side opening was made, remained full of decomposing clots. The limb wasted exceedingly, and a small slough formed on the side of the heel, but the gangrenous patch was only the size of a shilling. Four months after, pulsation could just be detected in the posterior tibial, and perhaps in the anterior.

Mr. SYMONDS read a paper on a case of Aneurysm occurring in a Stump. A man aged forty-six sustained a compound fracture of both bones of the leg in the site of an old syphilitic ulcer, on the floor of which the tibia was exposed; he was admitted into Guy's Hospital on Aug. 7th, 1883. Gritti's amputation was performed under full antiseptic precautions. The man was cachectic, and had lost a good deal of blood. Suppuration, with a foul discharge, occurred, and, later, two abscesses were opened on the outer side of the stump, and one on the inner. Healing took place very slowly, and when discharged, nine weeks after the operation, the stump was somewhat swollen and hard, especially on the inner side. Five days later he returned with blood oozing from a pin-like opening in the original cicatrix, and two days afterwards, when admitted, the bleeding was severe, and a large pulsating swelling was observed on the inner side. The skin over it was red and œdematous. There was thought to be an abscess communicating with the femoral artery. Before laying open the swelling the superficial femoral was ligatured, the whole thigh being œdematous. When cut into, blood alone escaped. The incision was enlarged, the clots turned out, when alarming hæmorrhage occurred from the femoral. This was found to come from a small aneurysm which had ruptured. This was laid open and the vessel tied above and below. The artery was isolated by passing a catheter into it. The man ultimately recovered, though slowly, and had a sound and useful stump. In his remarks, Mr. Symonds said the aneurysm had formed on the vessel two inches above the amputation site, and existed previous to the man's first discharge, and had ruptured soon afterwards. He referred to the rarity of the case, and to the general belief that aneurysm does not follow ligature of a healthy vessel from pressure, nor embolism of an artery unless the embolus be in a state of active change, and sets up a similar inflammatory and softening process in the wall of the vessel itself, which then yields to the ordinary blood-pressure. Admitting these facts, Mr. Symonds thought that a condition similar to that found in embolism must be looked for to explain the present case. It was suggested that the explanation of the cause of the aneurysm lay in the inflammatory state of the stump, and Mr. Symonds thought it best explained by supposing the vessel to have been involved in the acute inflammatory process which ended in other parts in the formation of pus, but in the vessel in softening only. He supposed that a peri-arteritis existed, reducing the vessel wall to an embryonic state, just as was seen to occur in the floor of ulcers, and in inflamed connective tissue. The localisation was explained by supposing that at the point affected the vessel formed part of the wall of an abscess or sinus. In support of this suggestion, the condition of the vessels in the walls of phthisical cavities, from which hæmorrhage occurred, was cited. Here, either an aperture in the wall of the vessel was found or an aneurysm. The latter change, he believed, was not uncommon in phthisis, and Mr. Symonds suggested that aneurismal dilatation will be found to precede secondary hæmorrhage in stumps more frequently than is now supposed. A paper which he published in the Transactions of the Pathological Society, vol. xxxv., page 146, was referred to as illustrating the case. In this paper two vessels affected with acute arteritis were described and figured, on one of which several aneurysms also had formed, secondary hæmorrhage resulting from the rupture of one of these. Referring to his suggestion in the above paper, that in secondary hæmorrhage an unhealthy condition of the wound and vessel existed, and that the bleeding was determined not so much by failure of clot formation as by suppurative arteritis, Mr. Symonds said that the present case gave support to that view, and brought into harmony hæmoptysis and secondary hæmorrhage. He suggested that in both the processes, so far as regards the vessel, are identical, and result sometimes in the formation of an aperture, and sometimes of an aneurysm.

Mr. T. BRYANT was disposed to agree with Mr. Symonds' views, and believed that secondary hæmorrhages usually resulted from an arteritis originating about the seat of injury of the vessel. Reference was made to the case of a man with compound fracture of the thigh, for which amputation was performed; so rapid was the healing that only one sinus discharged purulent fluid at the end of two weeks; but fatal hæmorrhage occurred at the end of the fifth week. The femoral artery was found to be diseased by suppuration that had destroyed the coagulum. At the time it was suggested that the arteritis was due to torsion of the vessel, but Mr. Bryant did not adopt that suggestion. He asked why Mr. Moullin laid open the traumatic aneurysm in the first instance, instead of ligaturing the external iliac artery.—Mr. MOULLIN said the skin was so œdematous and red that it appeared as though suppuration had occurred.—Dr. GOODHART agreed with Mr. Symonds that cases of aneurysm from embolism and hæmoptysis from aneurysms in pulmonary

Digitized by Google

cavities supported his views of surgical secondary hæmorrhage. Years ago he had taught that such hæmorrhages were due to suppuration which had extended along the tract of the artery. As the result of Listerism and consequent freedom of wounds from suppuration, he had not during the last five or six years seen cases of the kind.—Mr. PEARCE GOULD asked Mr. Moullin why the upper ligature was placed so far above the wound of the artery, thus leaving the deep epigastric and circumflex to supply blood below it.—Mr. BENNETT inquired of Mr. Symonds whether ligature of the common femoral would not have been preferable to that of the superficial femoral artery, and then why he had ligatured above the aneurysm at all; would not the use of a tourniquet and local treatment of the aneurysm have answered all purposes?—Mr. MANSELL MOULLIN said the aneurysm was situate immediately under Poupart's ligament, and he could not have reached the artery below the ligament. No other artery was ligatured.—Mr. SYMONDS, in reply, said it would no doubt have been better to have selected the common femoral for ligature, and admitted that it would have been better still to have controlled the vessel by a tourniquet, and then to have dealt with the aneurysm; but he did not do this because he thought there was pus in the cavity, and considered that the hæmorrhage might have proved more difficult to control.

Mr. GOODHART read notes of a case of Intussusception of the upper part of the Jejunum, of twenty-one months' standing. Its clinical interest depended upon its long duration and upon the resemblance of the abdominal tumours during life to a floating kidney. The case occurred in the practice of Mr. Sandford Arnott of Brixton. The patient, a girl aged nineteen, had been first seen a year and three-quarters before her death, and was then suffering periodical attacks of vomiting and abdominal pain, with progressive wasting. A knotty irregular tumour was felt in the lower part of the abdomen above the uterus. She then attended the out-patient department at King's College for eight months, and subsequently at University College, suffering from obstinate constipation, fæcal tumours, and what was thought to be a floating kidney. She was relieved by enemata of sulphate of magnesia, but, notwithstanding, her attacks recurred, and in these she was frequently seen by Mr. Arnott. The abdominal tumour never disappeared, but latterly it altered its position, and came to correspond with the situation of the left kidney. It varied in size and shape, some days being decidedly kidney-shaped, and generally it had a curve in its length, the concavity being towards the umbilicus. She was seen by Dr. Goodhart in her last attack, and was then pale and thin, although not appearing extremely emaciated; her mother described her as hardly ever free from sickness for more than a week, the actual attack lasting generally twenty-four to thirty-six hours. Lately she had been sick almost daily. The abdomen being exposed, the existence of a dilated stomach was at once apparent, it occupied the upper half of the abdomen, and its muscular contractions were plainly visible; but below this, in the left inferior quarter of the abdomen, was a second tumour, running from the flank obliquely downwards towards the pubes. This was the mass that had been felt throughout the progress of the case. It was an elongated tumour that underwent slow rhythmic alterations, becoming alternately hard and soft, and was obviously some part of the intestine "in labour." Vaginal and rectal examination gave no additional information. However, it was clear that there was some intestinal obstruction, although there was no sufficient material for determining its exact nature. She had never passed any blood, the evacuations being always of a light-brown colour, and, although she suffered from constipation, it was never such as to resist the action of an aperient. It was arranged that she should be admitted to Guy's Hospital, but before this was accomplished she died, apparently from the exhaustion of the continued vomiting. Mr. Arnott and Dr. Goodhart made an inspection. The dilated stomach occupied the greater part of the abdomen; below, and to its left, in the inguinal region were two or three coils of small intestine—small, but prominent, as if something pushed them up from behind, and on turning them aside a large intussusception was seen; it ran from near the spine into the pelvis, and looked more like rectum in thickness and size, but it proved to be small intestine, the neck of the intussusception being at the commencement of the jejunum. It was about eighteen inches in length, and when further examined was found to be associated with, and no doubt caused by the existence of, large polypoid masses of growth which sprang from the mucous membrane of the small intestine in several parts. In reply to Mr. Bryant, Dr. Goodhart stated that at no time was any blood passed per rectum, and there had been no actual constipation.—Mr. R. J. GODLEE mentioned a case of intussusception that existed without producing constipation. It occurred at the North-Eastern Hospital for Children, and the child passed a large quantity of fæces. Another case happened in University College Hospital many years ago; there were symptoms of intestinal obstruction, which led to the performance of colotomy on the right side, but without any tumour to account for the obstruction being found. Later on abdominal section was performed, still without success. The patient recovered from both operations, and died afterwards, when a long intussusception of the large bowel was discovered.—Mr. BARKER said that in this case there was a tumour of the wall of the bowel that produced obstruction and led to the intussusception.

Mr. A. E. BARKER read notes of a case of Acute Intestinal Obstruction, followed by Acute General Peritonitis, for which he performed abdominal section, releasing the implicated bowel, and thoroughly sponging out the peritoneum, with the result of rapid recovery. The patient was a man aged twenty-three, who had enjoyed good health, with the exception of flatulent dyspepsia, up to Saturday, November 14th, 1885. At 7 P.M. on that day he had a loose motion with a feeling of sickness, and three or four minutes later was seized with a violent pain in the abdomen, and fell down, rolling about on the floor in the most acute suffering. This pain commenced at a point midway between the umbilicus and the right groin. At 7.30 he began to vomit, and continued to do so through the night, and next day, until Monday evening, when Mr. Barker was sent for. At the onset he was seen by Mr. Knaggs of Camden-road, who gave large enemeta with opium internally, and hot fomentations over the abdomen. This treatment was continued with much judgment for the next forty-eight hours, but with no relief. On the contrary, the pain increased, and became general over the whole abdomen, the vomiting continued of a grass-green colour, but never became stercoraceous, the abdomen grew more and more distended, and the centre of acute tenderness shifted to the left side of the umbilicus. The peritoneum also began to fill with fluid, there was complete obstruction of the bowels from the first, and no flatus was passed. No distinct tumour was to be felt anywhere. When seen by Mr. Barker on Monday evening the condition was very grave, and he at once decided to perform abdominal section, regarding the case as one probably of obstruction from a constricting band, or from volvulus of the small intestine. With strict antiseptic precautions, the abdomen was opened in the middle line from the umbilicus to the pelvis, and was found to contain much flaky serum and free gas; the intestines were coated with lymph and moderately distended. The small intestine was now passed through the fingers from below upwards, until the middle third of the jejunum was reached. When this was drawn upon, there came a sudden rush of fluid through the portion held in the fingers, and the next moment there came out a loop of bowel deeply congested and ecchymosed, and distended to about three or four times its normal girth, and containing much fluid. Beyond this loop the gut was distended and moderately congested, but was sharply marked off against the implicated loop by the absence of ecchymoses. The bowel was now passed through the fingers downwards, to make sure that no other obstruction existed, and then the cæcum and vermiform appendix were turned out of the wound and examined with the same object; they were quite sound, though sharing in the inflammatory distension and congestion to a slight extent. The hand was now passed into the abdomen, and every part of it was explored, but nothing further was found. The gut having been carefully cleansed was now replaced, and the whole abdomen was mopped out with carbolised sponges, passed into every recess on long holders. The greatest accumulation of inflammatory products was found in the flanks and pelvis, and required repeated sponging. When the whole cavity had been cleaned the wound was united with seven deep and two superficial carbolised silk sutures in the usual way, and was dusted with iodoform and dressed with salicylic wool, secured with a broad binder. The patient bore the operation well on the whole. He had a good deal of pain in the night, and vomited twice before

Digitized by Google

morning. The vomited matter was no longer bilious, but consisted of watery altered blood. It came up for the last time at 9.30, twelve hours after operation. The patient progressed extremely well from this time, the peritonitis disappearing rapidly. The wound was dressed for the first time on the fifth day, and was then found united by first intention. Five of the stitches were taken out, and the wound was supported by broad strips of sticking plaster applied directly to the skin with salicylic wool and a binder over all. On the seventh day the remaining stitches were removed, and the wound was supported as before. On the eighth day a motion was passed spontaneously, and again on the ninth. These motions were stained with old blood. On this day, owing to an error in diet, he vomited and burst open the upper two-thirds of the wound, in spite of the strapping, and a knuckle of the intestine protruded. On seeing this six hours later, Mr. Barker removed the dressings, cleansed the protruded gut under the spray, wiped out the abdomen and the wound, and replaced the gut. The opening was closed as before, and similarly dressed. The temperature in the rectum rose on the night following to 102°, but beyond this there were no disquieting symptoms throughout convalescence, the patient being able to take light solid food a couple of days later. The wound healed in great part by first intention, but some of it by granulation. In reviewing this case, Mr. Barker dwelt upon the following points:—1. The nature of the obstruction. 2. The performance of abdominal section in the midst of acute general peritonitis. 3. The rapid disappearance of the latter after operation. He pointed out that from a comparison of this with recorded cases there could be no doubt that it was a case of volvulus of the jejunum, a very rare condition. The whole case corresponded closely with the few others on record, only one of which had been operated on. The onset of general peritonitis he regarded as an extra reason for early operation in such cases, and showed that this view was supported by pathological reasoning and clinical experience. The rapid disappearance of the peritonitis, due to the release of the intestine and cleansing of the abdominal cavity, was then commented on, and it was pointed out that the good result was, besides, in great part to be attributed to the judicious treatment of the case from the first with opium and enemata, and the comparative rest that the bowels were then placed in up to the time of operation, which was not delayed a moment after it was evident that other means had failed. That such an operation could only be successful when performed early and under the strictest antiseptic treatment was also averred.—Mr. BRYANT considered that the whole case was most successful, and a brilliant piece of surgery from beginning to end. He also agreed with the diagnosis, and thought that the only other condition that could account for the case would be a band. He asked Mr. Barker to explain how the gas developed in the peritoneal cavity. In his opinion peritonitis was not a contra-indication to abdominal section.—Dr. KINGSTON FOWLER referred to a case that occurred some years ago at the Middlesex Hospital which was the counterpart of Mr. Barker's. To Mr. Hulke, who operated, Dr. Fowler suggested that the right side of the abdomen should be searched with a view to finding the collapsed intestine; this was actually done and the site of obstruction was easily found. It was thought to be a volvulus that had been untwisted suddenly by drawing on the intestine. The patient lived four days and passed several copious motions, but died of syncope without obvious cause. Dr. Fowler opined that it was much easier to handle collapsed bowel, and his suggestion had been followed by Mr. Pearce Gould and Mr. Clutton and others.—Dr. CARRINGTON raised the question whether Mr. Barker's case was not one of acute peritonitis, observing that acute peritonitis and effusion were not common results of acute obstruction. The diagnosis of volvulus rested on the ecchymosed condition of the loop of the bowel and the passage of blood-stained matter. Both these factors might be accounted for on the supposition that acute peritonitis had set up an acute enteritis.—Mr. BARKER, in reply to Dr. Carrington, urged that the lowest four-fifths of the bowel were certainly not inflamed, and the patient at no time passed blood-stained fluid in the motions, or with the enemata; then, again, the work of Mr. Treves showed that acute peritonitis was very frequent—four out of eight cases—in the recorded instances. The intestine was not collapsed below the volvulus, but was slightly distended, which might be attributed to the peritonitis. The mode of onset and the remarkable way in which the symptoms disappeared after operation also favoured the diagnosis of volvulus.

The following living specimens were exhibited:—Mr. R. J. Godlee: A case Illustrating the Effects of Injury of the Cervical Sympathetic; a large (? neuro-fibromatous) tumour was removed from the right side of the neck of a girl aged eight, the pupil on that side was small, dilated but slightly when shaded, not at all with cocaine, contracted to light and in accommodation, dilated with atropine. Mr. R. W. Parker: Congenital Tumour of the Neck in an infant two months old, which almost disappeared during inspiration, being most prominent during the act of crying. Mr. G. H. Makins: Congenital Syphilis in a boy aged seventeen, with thickening and elongation of radii and tibiæ. Mr. C. Ballance: Compound Depressed Fracture of the Skull in the Right Temporal Region; removal of large pieces of bone, recovery.

EPIDEMIOLOGICAL SOCIETY.

Diphtheria.

A MEETING of this Society was held on Wednesday, Feb. 10th, Dr. Walter Dickson, R.N., President.

In a paper read by Dr. D. ASTLEY GRESSWELL on Diphtheria as a Chronic Malady in particular Individuals, with liability in them to Recrudescence, he put forward the following questions: "Is the chronic tonsillar inflammation which is left in particular persons after an attack of diphtheria due to continued sojourn in them of the material cause of diphtheria, and do the violent reactions of the tonsils of these persons to weather changes involve likelihood of rendering them diphtheritically infectious?" He had of late, while prosecuting inquiries into diphtheria in various parts of the country on behalf of the Local Government Board, come across a considerable number of persons who had been suffering from this condition, and he thought of them as having been the centres for dissemination of the virus of diphtheria in as many as six outbreaks of diphtheria. Dr. Gresswell detailed these outbreaks. In one of the outbreaks a boy who contracted diphtheria by personal infection in July, 1883, and who ever since had been subject to sore-throat, seemed to have been such a centre. In another instance a girl had been such a centre. The orphan inmates of an asylum were mentioned as having probably maintained diphtheria in their own persons for several years. In a family in which diphtheria had been repeatedly manifesting itself for some years past, one member seemed to have been an almost constant source of infection. He showed from these examples how the prevalence of diphtheria might be supposed to be sustained in a community. Analogies were drawn between the manifestations of chronic and recrudescent diphtheria and the manifestations of certain other diseases—syphilis, glanders, typhoid fever, &c. Special stress was laid upon the analogy which diphtheria in acute and chronic phases presented to gleet and gonorrhœa. Dr. Gresswell thought of rejuvenescence, as known amongst the cryptogamia, as being a phenomenon of like nature with that of the revival of the activity of diphtheritic and other virus in a person once infected by the virus. Finally, he dwelt upon the unwholesomeness of the dwellings in which these persons have generally lived; and he concluded with an exhortation that our dwellings might be made wholesome, and that the special attention of the therapeutist might be given to those persons who suffer from chronic tonsillar trouble sequent upon an attack of diphtheria.—In the discussion which followed, the President, Sir W. Smart, Dr. Thorne Thorne, Dr. Lawson, Dr. McKellar, Dr. Moir, and Mr. C. E. Paget took part.

SANITARY PROTECTION ASSOCIATION. — The fifth annual general meeting of the members of this Association was held on the 27th ult., when the council congratulated the Society upon the continued increase in the number of members. During the past twelve months there have been 424 first year's inspections at the residences of new members, 456 annual inspections, 282 inspections of works, 72 special inspections, and 30 inspections at Eton. The latter inspections were at the College and masters' houses. The statement of accounts presented showed the total receipts as £2422, and the total expenditure £1948, leaving a balance in hand of £474.

Reviews and Notices of Books.

Practical Bacteriology. By EDGAR M. CROOKSHANK, M.B., F.R.M.S., Demonstrator of. Physiology, King's College, London. London: H. K. Lewis. 1886.

WE warmly welcome the appearance of this very handsome and practically useful book. Its author modestly styles it on the title-page "an introduction to practical bacteriology based upon the methods of Koch," but it is amply sufficient for any worker in this continually extending field of research. The publication of such a work, which supplies a distinct need, serves to remind us of the very great importance which the subject of bacteriology is attaining. It is not so long since the relation between micro-organisms and disease was regarded as hypothetical and visionary. Now we are convinced of its occurrence, for it is supported by an array of demonstrable facts, thanks to the large body of patient and careful investigators armed with the powers supplied by all the technical improvements of modern microscopy. The methods which have been elaborated to determine the presence and distinguish the varieties of bacterial organisms, and to prove their intimate connexion with morbid processes, are as delicate and as trustworthy as any employed in scientific research. But the study demands for its pursuit the devotion of much time, extreme care, and no little skill, and hence it has been pursued by comparatively few. In this country, especially, the bacteriologists form but a slender band, which will doubtless receive many recruits when so excellent a manual as the one before us becomes widely known. Nevertheless we venture to think that the time has come for a public recognition by the higher teaching bodies of the importance of this branch of science. It needs a laboratory specially fitted with appliances solely for its pursuit, whilst those who prosecute the research require to be biologists quite as much as pathologists. The institution of bacteriological laboratories should, then, we think, be seriously advocated, and we may appeal to the Universities to take the lead and found chairs of bacteriology, which should no longer be dependent for its study upon private enterprise, or be expected to form a part of the pathological courses. For just as the pathologist has to extend his range of view far beyond the regions of bacteriology, so also must the bacteriologist pursue his researches outside the limitations of pathology. We confess to a dread lest the progress both of pathology and of bacteriology suffer by the endeavour to combine the two branches of science, simply for the reason that at one most important point—that of the etiology of disease—they necessarily commingle.

It is impossible to avoid such thoughts in the presence of a work like this of Mr. Crookshank's, which shows how vast is the field covered by bacteriology. The style and matter of the book are wholly commendable. It is drawn up on a very systematic plan, and the details of the laboratory are expounded with great care and sufficient fulness to make them useful to all, whether those to whom these methods of research are familiar, or those who may desire to begin this fascinating study. In the first chapter are described the apparatus and material requisite for the laboratory; in the next the methods of examination of bacterial organisms in various media, and in cultivations; then follows a description of the preparation and staining of sections of tissues, the preparation of the several nutrient media and the methods of culture, the subject of inoculation experiments upon animals, and, lastly, the examination of animals so inoculated for the detection and isolation of the bacteria. Mr. Crookshank has certainly succeeded in imparting an enormous amount of information in this part of his work, which makes it just what a laboratory handbook should be.

The second part consists of a systematic description of all known micro-organisms, to which, in the case of the more important, are added practical directions for their detection. A comparatively brief, but interesting and accurate, review of the progress of knowledge concerning bacteria, and especially of their classification, introduces this part. The author adopts, and indeed closely adheres to, the classification given by Zopf in his monograph "Die Spaltpilze." At the same time it is fairly acknowledged that the arrangement of these minute organisms is a provisional one, and that morphological characters often do not indicate specific differences, which are to be sought in the whole life-history of the microbe. Some idea of the degree to which the search for micro-organisms has been carried may be gathered from the simple fact that, besides the eighty-one species described in this chapter, there are no fewer than eighty others which receive notice in the following chapter as having been observed by writers, but either not described or not distinguished as distinct species. The largest number of micro-organisms are to be found amongst the bacteriaceæ, with its six genera and forty-seven species, and to these may be added forty-one other species more or less indeterminate. Amongst the five genera of coccaceæ there are thirty species described, but the indeterminate class contains no fewer than twenty-five varieties of micrococcus and three of staphylococcus. The characters of each variety are clearly and succinctly set forth, the more important—as the bacterium pneumoniæ crouposæ, spirillum choleræ asiaticæ, spirillum obermeierii, bacillus anthracis, bacillus tuberculosis, and bacillus typhosus, &c.—being dealt with in fuller detail, with additional instructions as to the best methods of their detection. As an example of the mode of treating the subject we may cite haphazard the following, p. 131:—

"BACTERIUM UREÆ (Micrococcus ureæ, Cohn).—Cocci 1·25—2 μ in diam., singly or in chains and rods. The rods split up by division into chains of cocci, and the latter are finally set free. The cocci increase further by subdivision, and a jelly-like membrane develops around them. Masses of cocci exist in the form of irregular or rounded lumps. Cultivations after twenty-four hours consist exclusively of rods, after forty-eight hours of cocci-chains, and in fourteen days of zoogloeæ; the cocci transplanted into fresh nourishing solution again grow into rods. These observations point to the existence of a pleomorphic species—*Bacterium ureæ;* and the former nomenclature, Micrococcus ureæ, must be regarded as untenable. They are aerobic; occurring in urine, they set up ammoniacal fermentation, converting urea into carbonate of ammonia."

In the appendix is given an account of the yeast and mould fungi, and also instructions for the examination of air, soil, and water.

A notable feature of the volume consists in the number and excellence of the coloured plates and engravings which abound. They alone deserve careful study, and they are simply invaluable as illustrations of the text. The bold type in which the volume is printed forms also an attraction which is not to be lightly disregarded. In fine, we are fairly justified in the opinion that the work is one which in every respect deserves, and will doubtless receive, a foremost place in scientific literature.

The Life of Sir Robert Christison, Bart., M.D., D.C.L., Professor of Materia Medica in the University of Edinburgh. Edited by his SONS. In Two Volumes. Vol. I.: Autobiography. William Blackwood and Sons, Edinburgh and London. 1885.

THE autobiography of any fairly efficient man covering fifty years of his active life, if well done in a literary respect, could scarcely fail to be of interest. Human life is a far more interesting piece of natural history than we are apt to imagine in these days, when it sometimes seems that to be considered interesting things must be visible only with

Digitized by Google

a microscope or a telescope. The interest of any human life increases of course with the individual qualities of it, and with its relation to others. In the case of Sir Robert Christison we have the life of a man who succeeded in attaining a considerable longevity, and who at any stage of life seemed to be up to his duty, and even his opportunities, and who filled for a long period a large space in the eye of his illustrious city and university, and had played no mean part in the history of British medicine, of medical jurisprudence, and of medical education. In a succeeding volume we shall see more of what others think of Christison; in this, the first volume, we see what he thought of himself, and that is a fine subject for study. Some very worthy men have had an excellent opinion of themselves, and every page of this autobiography justifies us in saying that Christison was one of those men who after careful stock-taking came to a fair amount of self-approval. He was not one of those men who prized popular applause. He doubtless thought with Pope—

> "One self-approving hour whole years outweighs
> Of stupid starers, and of loud huzzas."

And yet a very superficial knowledge of Christison, the professor, the physician, the witness in great cases, the member of the Medical Council, &c., will suffice to show that his high opinion of himself was shared by all good judges, and that in the multifarious subjects in which he took an interest the materials for a judgment were scarcely complete till he had spoken.

It is difficult to analyse the different parts of this autobiography in any notice possible in our space: we must do the best we can. Let us observe the fact that Christison seems to have had an abiding habit of making notes of the events of his life. So it happened that when he had completed fifty years of his professorship, and he could not conveniently climb a high mountain—his favourite recreation,—he bethought himself of finding complete relaxation and of saving his future biographers trouble, in compiling this autobiography, which abounds in everything that is high and good, and which will be read by most medical men, especially Edinburgh men, throughout the world. Lineage from the Vikings; High School contests of scholarship, and the history of High School rivals and contemporaries; the value of school successes as a prognostic of future success in life; the merits of classical *versus* scientific school-work; the Edinburgh University, and its long subjection to the Town Council; his voyages to London in Leith smacks; the London school and the backwardness of medical teaching when Christison came to St. Bartholomew's Hospital; the Paris school, and the charming word-portraits of its chief members, Majendie, Dupuytren, Orfila, and others; the fevers of Edinburgh, which Christison studied so well and took so freely; his six attacks of fever, with the careful observation for that time of a temperature under the tongue of 107°; the stories of Burke and Hare: the fortunate appointment to a physicianship in the Royal Infirmary in 1827, and his devotion to pathological and clinical work—are specimens of the material in which the volume abounds. And when we add that the literary style of the work is of the best, bold, correct, without pedantry, personal, faithful, whether relating a foolish duel in Paris or a contest for an Edinburgh chair, or the contradiction of scientific and legal opinion in courts,—we have said enough to justify an opinion that the book is one of the most valuable contributions to biography which we have recently had to notice, and to warrant us in looking forward with much interest to the second volume.

OUR LIBRARY TABLE.

The Student's Guide to the Practice of Medicine. By M. CHARTERIS, M.D. Fourth Edition. London: J. and A. Churchill. 1885.—The appearance of another edition of this little work shows that it is appreciated by students; and the author has certainly done his best to convey as much information as possible within its limited compass. Its revision has been undertaken upon the basis of the revised "nomenclature," and its value is enhanced by a copious Therapeutical Index and Glossary. The work is trustworthy, and may safely be recommended to the beginner, or used, as intended, for a "guide" to examinations; but it ought not to deter the student from seeking that fuller information which the larger text-books supply. The fear is that our examination system may tend to confine the student within too narrow limits, and that he is liable to be satisfied with a minimum of knowledge. The more excellent the manual for his purpose, the more likely is he to neglect that profounder study which, although beyond the requirements of an examining board, is very essential to the making of a sound practitioner.

Select Methods in Chemical Analysis (chiefly Inorganic). By WILLIAM CROOKES, F.R.S., V.P.C.S., Editor of the *Chemical News.* Second Edition. Rewritten and greatly enlarged. London: Longmans. 1886.—Mr. Crookes, whose discoveries in pure science have added so much to the empire of thought, has in this book conferred a most practical boon upon all who are engaged in chemical work. With labour which can only be appreciated by those whose lives are spent in the laboratory he has tested a large number of the new analytical methods which have been proposed of late years, and has arranged and sufficiently described those which were found to be useful and trustworthy. Of course the book is a compilation, but it is the compilation of a master who brings skill and judgment, and not mere paste and scissors, to bear upon his task; and equally, of course, it is imperfect, for the author has omitted methods which, being universally known, can be found in ordinary manuals. So greatly does the new edition differ from the old that it is correctly described as having been rewritten, but the old lines have been followed, and if the book is larger it is simply because so many new methods have been introduced. All the elements, even the rarest, are included. Thus we find minute directions for the separation of cerium, didymium, samarium, and lanthanum, the author justly considering that no one of them can properly be ignored. Such a work is obviously one for the chemist rather than the physician; but some chapters, notably the three last, which are devoted to general analytical processes, manipulation, and tables, will be of the highest value to all workers in physiological and hygienic chemistry. The description of modern methods of filtration and gas analysis, sufficiently illustrated by woodcuts, would alone render the book valuable to the physiologist. To the chemist it is essential.

St. Bartholomew's Hospital Reports.—The "In Memoriam—Francis Harris, M.D." has been written by Dr. Samuel Gee in his precise, truthful, and learned style. Dr. Norman Moore gives an introduction to "The Book of the Foundation of St. Bartholomew's," which work is very quaint and interesting. Here are a few headings of chapters:—"Of a Woman y take with the palsy"; "A Myracle of a Mayde"; "Of a Childe that receyvyd his Syght;" "Of an howse untouchid yn myddyl of the Fyer"; "Of a certeyn Yonge Woman." Drs. T. C. Shaw, Ormerod, Percy Kidd, V. Harris, S. West, Norman Moore, Habershon, A. E. Garrod, H. H. Tooth, Herringham, Ferguson, Roughton, Duckworth, Bullar, Haig, and Styan, and Messrs. Spicer, Owen Lankester, C. A. Norton, Walsham, and Butlin, contribute articles on various subjects. Dr. W. S. Church's note on the "Six Gifts of

Digitized by Google

Theophilus Philanthropos, or Robert Roole," an appendix to "Our Hospital Pharmacopœia and Apothecary's Shop," vol. xx., p. 279, is full of curious matter.

Royal London Ophthalmic Hospital Reports. Edited by MARCUS GUNN, M.A., F.R.C.S. Jan., 1886.—This, the first part of the eleventh volume, contains the following papers: 1. E. Nettleship on the Pathological Changes in Syphilitic Choroiditis and Retinitis. 2. Arthur Benson on the More Modern Operations for Trichiasis. 3. W. Jennings Milles: The Curator's Pathological Report, embracing the subjects of Detachment of the Vitreous Body, cases of Intra-ocular Sarcoma producing Sympathetic Ophthalmitis, and cases of Sympathetic Inflammation of the Eyeball. 4. W. A. Brailey on Intra-ocular Sarcoma exciting Sympathetic Disease. 5. E. Nettleship: Miscellaneous Observations and Cases. 6. Marcus Gunn on Sympathetic Inflammation of the Eyeball.

The Journal of Physiology. Edited by M. FOSTER. Vol. 7, Part 1.—This part is entirely occupied with a long and valuable paper by W. H. Gaskell on the Structure, Distribution, and Function of the Nerves which Innervate the Visceral and Vascular Systems. The memoir is illustrated with four plates.

Burdett's Official Intelligence.—Mr. Burdett's admirable book reaches its fifth number in the volume for the present year. To such as are at all familiar with the literature of the Stock Exchange it will be unnecessary to say more than that the present volume will fully sustain the high reputation for completeness and accuracy which the work has enjoyed from the first. The book, indeed, stands quite alone in English literature, giving as it does a financial abstract of every joint stock company in the United Kingdom, and a statistical account of every negotiable security, whether British or foreign, that is offered on the Stock Exchange. It is not only thus encyclopædic in its range, but it is equally conspicuous for the fulness and precision of the information conveyed. The author has made excellent use of his position to collect his facts at first hand from those who know them best, and has made them accessible by an excellent system of arrangement and a copious index. A notable feature of this work are the dissertations on financial topics, which form a preface to the statistical matter. These are of much more than merely passing interest. For example, the number now under review contains as clear a *résumé* of the fiscal system of Great Britain, under the title of "Imperial and Local Taxation," as can well be compressed into five-and-thirty pages. Indian finance, again, is made the subject of another essay—less complete, indeed, but still full of suggestion and information for the general reader, who may have Indian securities in his view. Another paper of peculiar interest at the present time is that on "Colonial Loans, Finance, and Development." In a word, whether regard be had to the literary or the tabulated matter, the book will be pronounced excellent by everybody who has recourse to it, and as there is no class throughout the community to whom the judicious investment of savings is a matter of more vital importance than it is to medical men, we gladly acknowledge the service which Mr. Burdett has rendered to them.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—The annual court of governors of this institution was held on the 26th ult., when it was stated that during the past year the in-patients had numbered 479, the out-patients 6015, and the patients attended 28,054. The committee appeal most urgently for new annual subscriptions in order that the income of the hospital, which is now about £2000 per annum less than the required expenditure, may be placed on a firmer and more permanent basis.

VACCINATION GRANT.—Mr. S. A. Jolly, of Puddletown, Dorchester, has received the Government grant for efficient vaccination in his district.

New Inventions.

THE BURROUGHS MODEL MEDICINE-CHEST.

MESSRS. BURROUGHS, WELLCOME, & Co., of Snow-hill, have submitted to our notice their new medicine-chest, which they claim to be compact, portable, of good quality, and moderate cost. Most of the medicines contained therein are in the form of the well-known Wyeth's compressed tablets, consisting solely of the actual drugs. Those which are intended for local effect upon the mouth and throat are compressed quite hard, so as to dissolve slowly, and to have the effect of a prolonged gargle, as, for instance, the tablets of chlorate of potash, to the utility of which we have on a previous occasion directed attention. Those tablets which are intended for internal administration are so compressed as to disintegrate readily. In addition to these tablets, the chest also contains "valoids" of belladonna and aconite, which are stated to represent the activity of the best quality of the drugs in a highly concentrated form, each minim representing a grain of the drug. Another bottle contains "eucalyptine," a preparation of the eucalyptus. The remaining contents of the chest comprise peptonising powders (Fairchild's), zinc ointment, spermaceti ointment,

bandages, antiseptic pads, and a measuring-glass. With regard to the latter, we would suggest that it would be much improved if graduated in drachms, &c., instead of the domestic but unsatisfactory "spoons." The box is neatly made, and forms a really handy and excellent little medicine-chest. It should, however, containing as it does concentrated solutions of such deadly drugs as aconite, belladonna, &c., be provided with an efficient lock and key, instead of the ordinary hasp with which the specimen sent to us is furnished. The bottles which contain the solutions alluded to are of blue glass, and so shaped as to avoid all chance of error; but they might be more obviously labelled with the danger signal of "poison," and their corks might be more efficient. Doubtless, however, these are inadequacies which the designers will remedy before submitting the chest to the profession. The complete contents are:—Tablets of salicylate of soda (5 grs.), Dover's powder (5 grs.), potass. chlor. (5 grs.), bismuth subnitr. (5 grs.), ammon. chlor. (3 grs.), nitrate of potash (5 grs.), bisulphate of quinine (2 grs.), potass. bicarb. (5 grs.), cathartic comp. (U.S.P.), "soda mint." and peptonic tablets, "valoids" of aconite and belladonna, eucalyptine, peptonising powders, zinc and spermaceti ointments, antiseptic pads for wounds, bandages, and a measuring-glass in case. It is certainly difficult to imagine how more could be included within so small a space.

THE LANCET.

LONDON: SATURDAY, MARCH 6, 1886.

A SUMMARY of the measure by which it is now proposed to amend the Lunacy Acts will be found in another column. The main provisions again set forth have been discussed from time to time; in fact, there is no feature of novelty in the Bill introduced by the present Lord Chancellor, and, except that the necessities of procedure required that it should be brought in by a member of the Government, the Earl of SELBORNE might have reintroduced it. In principle we have already expressed approval of the purposes formed, and, speaking generally, of the several means by which it is designed to compass them. There are matters of detail which will require to be discussed later on, but nothing will be gained by criticising clauses of the Bill until it has reached a stage of greater advancement. Indeed, it must be in the House of Commons that the fate of the measure is decided. We are glad to know that the Government is in earnest on the subject of lunacy law reform, and that it is prepared to afford greater protection to the sane, while the prompt treatment of insanity in its earliest beginnings is facilitated by the obvious policy of removing absurd restrictions. The extension of the voluntary system to England is of great importance. As regards the "private asylum question," we think that may be hopefully left to adjust itself, under the influence of a provision that public authorities may—it ought to be *shall*—provide for private needs. Meanwhile, though giving a cordial assent to this Bill as far as it goes, we can bate nothing of our original contention that the whole subject of certifying is in urgent need of a "root-and-branch" revision. The new safeguards to be created by this measure will doubtless be of some service, and in the absence of better help we accept them thankfully; but what is really needed is such a system as should place the treatment of mental disease on a strictly professional footing, by making it a medical function, and permitting the practitioner to act solely as a physician, without loading his actions with the intolerable burden of a legal significance. Medical certificates ought to have no force as legal warrants. Such a force is wholly foreign to their nature and purpose, and alien to the character of those who sign them. Physicians ask nothing from the law in aid of the treatment of the insane. They do not desire more control over their patients than the common law gives every citizen for the protection of his neighbour or himself in case of emergency, and which amply covers all a practitioner needs to enable him to treat a case of delirium or excitement arising from any cause. The requirement of formal certificates which brand the persons named therein as lunatics and disable them from the exercise of legal rights, such as the making of wills and the signing and execution of deeds, is a monstrous demand on a profession which is, or ought to be, exclusively engaged in the remedy of morbid affections, and has neither the time nor the inclination to do dirty work for the law.

THE presidential address recently delivered by Dr. DALLINGER before the Royal Microscopical Society afforded an insight into the extent to which the modern improvements in microscopical technique are enabling the observer to penetrate the mysteries of cell life. The nature and functions of the nucleus have long been subjects of controversy; and we have had opinions ranging from an admission that the nucleus is the most important element in the cell to those which regard it as inert and useless. The remarkable researches of FLEMMING and STRASSBURGER upon karyokinesis have practically determined the question of the importance of the nucleus, besides showing how complex is its structure; and Dr. DALLINGER'S studies, although in the same direction, have carried us a great deal further. He observed the behaviour of the living nucleus in the lowliest monads or septic organisms, and has, by the use of the highest available microscopic powers, thrown a flood of light upon the subject. These organisms multiply ordinarily by fission—a process in which the nucleus shares; but the two last products of a long series of fissions are seen to fuse together, and after a period of rest their investing envelope bursts, liberating numbers of germs. These germs, at first semi-opaque, become within from fifteen to thirty minutes hyaline, and increase in size up to a certain point. The germ now appears devoid of vitality, but in point of fact it is the nucleus itself which has passed into a resting state for the purpose of elaborating its internal structure. A delicate investing membrane is formed, then the protoplasmic substance becomes granular, gradually assuming formed characters in the production of extremely delicate threads, which by a process of weaving or plaiting soon bestow on the whole of the nuclear body a definite structure. Material now forms on the exterior of the nucleus, until the organism finally attains its adult size and begins to move. In the monads observed the flagellum appears suddenly, and can be seen to be derived from the nucleus. Thus, even in these unicellular organisms, we seem to have a sexual process alternating with a process of mere fission. The union of two organisms, their fusion into one, is followed by the production of germs; these germs are the nuclei of the future organisms, and they contain within them the power of developing into the fully formed monad, the production or secretion of the cell-protoplasm being preceded by a series of changes within the substance of the nucleus itself—changes which may be compared with those occurring in the impregnated germ of higher forms of life. Equally interesting are the facts which Dr. DALLINGER observed in the further life-history of these microbes. He says that in about five minutes after the adult stage is reached fission commences, and he has been able to see that this process of self-division is initiated in the nucleus. Indeed, we have here the karyokinetic process reproduced, for the first indications of change are observed in the plexiform structure, which becomes in great part aggregated at one pole of the nucleus; and then ensues the division of the

Digitized by Google

nucleus followed by that of the body-substance, the two nuclei presenting the plexiform structure throughout. When the fission process is at an end and is about to give place to the generative, then the organism takes on amœboid characters and fuses with its fellow. The fusion is complete—cell body and cell nucleus merging into one uninucleated organism; but before this happens the nucleus has lost its plexiform structure and becomes enlarged and milky-looking, finally diffusing through the whole body substance of the globular mass, which is then transformed into a germ sac. The process of generation is completed in about six hours, when the sac ruptures and gives issue to the countless germs whose further development was alluded to above.

A mere bald statement of these discoveries can give no idea of their importance, or of the patient labour involved in them. We are in the presence of the "infinitely little," and have been permitted to witness the process of generation in its simplest manifestation. It seems hardly possible that we can penetrate further; indeed it is questionable whether it is optically possible to produce more delicate instruments than those with which Dr. DALLINGER worked. Nor is it possible to go beyond the facts which he has adduced—as for example, to inquire into the nature of the influence, call it spermatic or other,—whereby from the fusion of two cells a host of potential cells arise, each of which has the properties of its parent, and is destined to undergo the same cycle of changes. But if we are limited by the imperfection of our faculties and instruments, we are yet made aware of a fact which is capable of the widest application—namely, that the cell-nucleus is possessed of inherent powers, which render it the essential constituent of the cell itself; that it constitutes the ultimate germ (and sperm) whence the organism is evolved. Moreover, we can grasp more clearly from these researches the rapidity with which the process of generation is carried on among these microbes, and are more fully impressed than ever with the teeming life that everywhere abounds. As Dr. DALLINGER remarked, "We are no nearer to the solution of what life is," but through him we have had displayed the vital process in its simplest expression. To attain this knowledge he must have devoted hours to continuous observation of one special monad; he must have watched and chronicled every change that it underwent, employing for this means the most exquisite apparatus that can be devised, with the result that biological science has been enriched by a series of facts which a short time ago would have been deemed to rank among the unknowable.

No branch of practical surgery is of more universal importance than that which deals with the arrest of hæmorrhage. Not only is bleeding an almost universal attendant on wounds, and the loss of the vital fluid if carried beyond a certain minimum degree a matter of extreme moment, but the arrest of all oozing from wounded vessels has an important influence upon the process of repair. The question is invested with the highest interest to the student, on account of the remarkable natural processes which participate in the repair of injuries to bloodvessels, and also from the enormous benefits which have accrued to mankind from the improvements which have been introduced into this department of practical surgery, and which stand out as chief landmarks in the history of the art. The introduction of the ligature is undoubtedly the greatest improvement ever made in the treatment of hæmorrhage, and so strong is the faith of surgeons in it that it would be a matter of the utmost difficulty to supplant it by any other measure. Two more modern methods of treatment, however, are destined in all probability very largely to limit the use of ligatures—viz., torsion and forci-pressure. Although torsion of arteries was known to the ancients, it was rediscovered and introduced into practice by AMUSSAT in 1828, and two celebrated French surgeons, VELPEAU and THIERRY, urged its claims, and largely practised it. About the same time FRICKE introduced it into Germany. Slowly it travelled over to England, where it excited little attention until the surgeons of Guy's Hospital—COOPER FORSTER and BRYANT in particular—and Mr. CALLENDER, showed that it was a simple and very trustworthy method of arresting hæmorrhage from even the largest arteries. Its superiority to the old hempen ligature is incontestable; but the introduction of unirritating and absorbable animal ligatures has somewhat altered the terms of comparison between ligature and torsion, and much more closely assimilated the two methods. In each case the separation of the end of the artery is avoided, and a button of tissue at its end is either slowly absorbed and replaced by living tissue or encapsuled by it. As, therefore, the *modus operandi* of the two methods is almost precisely the same, the comparison between them must depend upon the special readiness with which each may be employed. Both are alike rapid, and in dexterous hands certain; but torsion has the great advantage over the ligature of not requiring the aid of an assistant. The surgeon himself seizes the artery and twists it, while for the ligature it is necessary that while one holds the vessel in the forceps another throws the thread around it. A second great advantage on the side of torsion is that in its application the surgeon is entirely independent of others for the preparation of his material. But when using prepared catgut or such-like ligatures, the surgeon is dependent upon the maker of the catgut in the first place, and then upon its having been rendered completely aseptic. Atheroma or advanced calcification of an artery renders it very readily occluded by torsion, although, strange to say, it is even yet to be found in surgical text-books that for torsion to succeed, a healthy state of the artery wall is essential. There is one condition, however, which militates very powerfully against successful torsion, and that is peri-arteritis, or adhesion of an artery to its sheath; in such cases the vessel can be seized together with its sheath and easily ligatured, but torsion is almost if not quite impracticable. Torsion s also inferior to the ligature for the closure of wounded veins.

The case of the smaller arteries is again different; for torsion to succeed, it is important that the vessel be seized cleanly and gently drawn out from its sheath before it is twisted, and the smaller the artery the more difficult does this become. The same condition renders it difficult to surround a vessel cleanly with a ligature, and surgeons are in the habit of seizing a small bunch of tissues around a small artery and including the whole in the noose. There

Digitized by Google

is, however, one drawback to such a step, and it is that the ligature may slip and the bleeding burst out anew. It is just in such cases that forci-pressure is so valuable. Few instruments have done more to simplify operations than the valuable hæmostatic forceps introduced by KŒBERLE and SPENCER WELLS. The same principle had been made use of many years ago by DIEFFENBACH in his "bull-dog" forceps, but the modern instrument is vastly superior to his. The forceps can be used in two or three ways. Thus they are employed to compress strands of tissue previous to their division with a knife, or bleeding points are seized by them and occluded, until by torsion or ligature the wounded vessel is safely closed. But, in addition to this, they are of extreme value as sole hæmostatic agents. When an artery is compressed in this manner its two inner coats break across and curl up inside, while the outer coat has its elasticity destroyed, and is squeezed into a corrugated, flattened band. An internal coagulum speedily forms on the inverted inner coats, and the fate of the compressed end of the vessel is similar to that of the knob at the end of a twisted artery or to an aseptic absorbable ligature and the tissue it includes. Quite small arteries are very quickly occluded by such forceps, but when the vessels are larger it is necessary to observe two precautions. The first is to remove the forceps with great gentleness, in order that in so doing the compressed outer coat may not be opened out through the tendency of the tissue to adhere to the steel. The second is not to remove the forceps too quickly, but to wait until the blood has had time to begin the formation of the internal coagulum. The best way of employing this hæmostatic agent, in such a case as the excision of a tumour or the amputation of a breast, is to seize each artery as it spouts with a pair of forceps; then, when the excision is completed, and the surgeon has satisfied himself of the sufficiency of the operation, and that there are no other bleeding points requiring attention, the forceps should be carefully removed one by one, in the order in which they were applied. By adopting these precautions it is usually unnecessary to employ any other means for the arrest of hæmorrhage unless a considerable artery is wounded. Similarly, in an amputation, when the main vessels have been picked up and twisted or tied, if these pressure-forceps are applied to every point which bleeds when the tourniquet is loosened and removed, and then these forceps are carefully removed in the order in which they were applied, all the vessels will be found securely sealed in the great majority of cases. The arrest of hæmorrhage in operation wounds has been in this way reduced to the greatest simplicity, and not the smallest advantage has been the adoption of methods which can be employed by the surgeon unaided.

While, therefore, the aseptic ligature, properly prepared and applied, is a thoroughly trustworthy means of treating hæmorrhage, we would limit its application to the cases of large arteries in which torsion is inapplicable, to cases of hæmorrhage from smaller vessels not quickly arrested by forci-pressure, and to the case of wounds of large veins In the case of large and medium-sized arteries, where torsion is not specially contra-indicated, we believe it to be superior to the ligature, and in the vast majority of cases of bleeding from small vessels forci-pressure is the most simple, expeditious, and efficient means for its arrest which the surgeon has at his disposal.

THE metal tin, though long known, for it was used in the manufacture of bronze, has not entered to any large extent into the Pharmacopœias of this, or, so far as we know, into those of any other country. The word "bedil," which is translated "tin" in the Old Testament, "stannum" in Latin, and *κασσίτερος* in Greek, is not certainly to be identified with that metal, and, according to ROSCOE and SCHORLEMMER, it is doubtful whether the metal which the Phœnicians are said to have brought from the Cassiterides, whose exact locality was unknown to HERODOTUS, was really tin. It is certain, however, that the metal was known to PLINY, that after CÆSAR'S conquest it was obtained from the Cornish mines, and that DIODORUS SICULUS describes its conveyance to a small island named Iktis, the topographical features of which, as described by him, correspond accurately with those of St. Michael's Mount in Cornwall.

Most authors hold with ORFILA that tin has no toxic properties, since it is but slightly attacked by a solution of hydrochloric acid of the strength in which this acid exists in the gastric juice, and hence can only be absorbed in small quantity. According to Dr. PATENKO of St. Petersburg, who has lately devoted himself to the study of the toxic effects of tin, it has been administered in England in the metallic state, in accordance with instructions given by Dr. ALSTON, who published some lectures on materia medica in 1770. These instructions are that the patient should take a purgative of senna and manna on a Thursday before a new moon; on the following day an ounce of metallic tin is administered in four ounces of syrup; on Saturday half an ounce more tin is administered in two ounces of syrup, and the same quantity on Sunday; on Monday another purge of senna and manna is given. The success of the remedy, if it ever prove successful, has been attributed by some to the presence of arsenic, which is always present in ordinary tin; whilst MM. CAHOURS and SOLYET consider that an active compound, distannethyl, may be formed in the intestine and become the active agent. Other experiments have shown that the injection of the protochloride of tin into the jugular vein of a dog, in doses not exceeding five grains dissolved in ten parts of distilled water, causes death with tetanic symptoms in from one to fifteen minutes, or if ingested, vomiting, debility, and death. On post-mortem examination the gastric mucous membrane, and even that of the duodenum and jejunum, exhibited thickening and ulceration.

M. PATENKO'S researches, pursued in Professor VULPIAN'S laboratory, were confined to the metal itself and to the bichloride. He commenced by giving to two dogs three grains of chemically pure tin in powder once daily with the food, and continued its administration for six weeks. No indications of any injurious effects were observed; on the contrary, the animals preserved excellent appetites, and were lively and gained in weight. It was incidentally shown at the necropsy of one of the dogs that the metal had not caused the expulsion of numerous ascarides with which it was infested, nor of a tænia serrata. The urine contained no tin, nor was any found in the brain, liver, spleen, or

Digitized by Google

kidneys. The powder was present in the fæces. It did not therefore appear to be absorbed.

The administration of the bichloride of tin gave different results. The animals experimented upon were frogs, guinea-pigs, and dogs, and it was injected subcutaneously, thrown into the peritoneal cavity, and introduced into the stomach. When subcutaneously injected it caused, in small and diluted doses, local anæsthesia, which augmented and extended when larger quantities were employed. Strong solutions caused gangrene, which penetrated deeply, destroying not only the whole thickness of the skin, but subjacent organs, such as the liver and stomach. Injections made into the peritoneal cavity exhibited its caustic properties, but no special peculiarities. Injected into the veins, in doses not exceeding three-fourths of a grain, death rapidly followed, but the immediate cause of death was not apparent, and has not been ascertained, though it was probably due to the action of the agent on the central nervous system and upon the muscles. The action on the stomach was not marked; even when given in rather large quantities for some time with the food, it only caused indigestion. On the whole, therefore, the observations of Dr. PATENKO confirm those of previous experimenters, and show that the metal has no poisonous action, but that the bichloride acts essentially on the central nervous system and the muscles.

WE have somewhat recently commented on certain views which Dr. GRESSWELL has enunciated in connexion with the recurrence of diphtheria in families and with its appearance in individuals without apparent chance of its having been contracted from any recently acute case; and, as will be seen from our summary of the proceedings of the Epidemiological Society, these views were at the last meeting of that Society discussed at some considerable length. Any carefully considered opinions connected with the etiology of diphtheria are worthy of notice, for the disease is one about the causation of which little that is definite is known; and all who have had the opportunity of perusing the reports which Dr. GRESSWELL has prepared on diphtheria for the Local Government Board will at least give him credit for painstaking investigations into the matters concerning which he writes.

The special view to which we now advert is that diphtheria, instead of being merely an acute infectious fever, may become chronic and be marked with periods of infective recrudescence. Thus, persons have often been met with who, whilst suffering from this so-called recrudescent diphtheria, have apparently been the starting-point for the fresh infection of a large number of persons hitherto healthy, and indeed for a fresh outbreak of the disease in a community; and it has been found that the persons who have acted as the originators of such outbreaks have themselves been sufferers from diphtheria some months before, and that what has apparently been in them nothing but a slight attack of tonsillitis has developed infective properties leading to a diffusion of the original malady in a marked form. So, also, children who have been apparently quite cured of their diphtheria, and whose fauces have assumed a healthy appearance, have some months after been found with diphtheritic patches about their tonsils, and they have then acted as centres of infection to others. It is of course somewhat difficult to say whether such cases are due to renewed infection, or whether they result from a renewed vitality of the original infection, but from the number of instances in which these sets of conditions have been observed Dr. GRESSWELL is inclined to the latter view, and he has taken occasion to support his opinion by reference to a considerable number of cases which he regards as somewhat typical examples of the occurrences referred to.

The analogy of other diseases is also quoted in support of this view. Thus, syphilis is cited as a disease which first appears as an acute disease and then in a chronic and recrudescent phase, and this without there having been any chance of renewed infection. Ague and its periodic recurrences, and the relapses of such diseases as relapsing fever and enteric fever are quoted as bearing upon the point. Glanders, again, is referred to as being acute on the one hand, or chronic and associated with active states when infectiveness reappears on the other hand. The relation of gleet to gonorrhœa is also spoken of in the same connexion, and a further analogy is found in certain phases of the development of protoplasmic molecules. It is finally suggested that the recrudescence of disease in the cases referred to is nothing but the rejuvenescence of a specific parasitic organism after one of those stages of rest which may be observed in the life history of so many organisms.

During the course of the discussion on Dr. GRESSWELL'S paper it was pointed out that many of the phenomena of diphtheria to which he had adverted might be explained in a very different way; but we do not refer to the question with the object of supporting one set of views or the other. We have rather drawn attention to the paper in order that other observers who are likely to have practical acquaintance with diphtheria in all its phases may have an opportunity of testing the validity of the view which has been formulated. Any step in the direction of acquiring accurate information concerning the various phases which this obscure disease exhibits, or of getting rid of views as to it which will not bear the test of experience, will help towards the solution of a difficulty which is very generally felt.

Annotations.

"Ne quid nimis."

THE HOMES OF THE WINDSOR POOR.

THE complaints we have raised concerning the housing of the poor at Windsor promise to bear fruit. As we explained at the time in our special report on the subject, the grievance is of old standing, but till recently it has always been successfully hushed up. The Rev. Arthur Robins has for more than ten years agitated this question, and consequently he became one of the best-abused men in Windsor. There were interests at stake which the necessary improvements might compromise; and many efforts were made to conceal the truth from both the Royal Family and the public. This, however, was no longer possible after the publication of our report minutely describing some of the slums of Windsor particularly as the matter was then taken up by the press generally. The *Standard* and *The Times* gave great prominence to the grievance, the provincial newspapers reprinted all the information, and even some Canadian and Australian

Digitized by Google

papers protested against the shameful condition of the Royal borough. We need scarcely remark that, in such a campaign, the partisans of sanitary reform early elicited the full sympathy of Her Majesty. Indeed, the entire Royal household and also the household troops are naturally at one with us in the desire to see the poor of Windsor profit to the full by the sanitary legislation which till now has remained almost a dead letter in this historic town. The force of outside public opinion having thus fairly turned the tide, many of the notable inhabitants who but a short time ago protested that the complaints were grossly exaggerated are now loud in their demands for reform. The indignation meetings which were to be held against us are all forgotten; even the Rev. Arthur Robins, who, it was suggested, deserved to be thrown into the Thames, may soon be recognised as a public benefactor. In any case, the Bier-lane district, which he has so long denounced, is at last definitively condemned. Mr. Richardson Gardner, M.P., recently presented a scheme to the corporation for rebuilding the whole of this slum. He proposed to raise, we believe, some £50,000 in £5 shares; and the company to be formed will be under the patronage of all the influencial residents in the neighbourhood, including two Royal princes, whose names, however, we are not as yet at liberty to mention. The vile houses, constituting the courts leading into Bier-lane, will be pulled down, including the rag shop and the slaughter-house that stand within a stone's throw of the Castle walls. Modern dwellings will be built in their stead, and these, it is maintained, will yield a fair interest on the capital invested. Already there are five good new cottages in Bier-lane, which, though rented at only 4*s*. 6*d*. a week, are, financially speaking, a sound venture. The work which will now be done might have been undertaken long ago, seeing that at present there seems little or no resistance. It must nevertheless be acknowledged that the storm we have succeeded in raising by means of the press has materially contributed to bring about this result; for the land can now be obtained at a reasonable price. Some time ago a gentleman offered to buy four or five hovels, but could not do so because the owners were making about 40 per cent. out of this low-class property. Now the cry is so strong, and the prospect of the intervention of Parliament so far probable, that it would not be safe to ask any exorbitant price for the land. The district therefore will be bought up and rebuilt, and thus the Alsatia of Windsor, where both the cholera and small-pox epidemics first broke out, will be swept away. Model cottages and houses, built, if possible, in a style to match with the grand old Castle which will tower above them, are to be completed in time for the Queen's jubilee. The work of regeneration must not, however, stop here. Close to the Castle and near the station, Bier-lane is the most obvious eyesore of Windsor; but there are other equally vile hotbeds of dirt, dilapidation, and demoralisation. The defects of South-place are, from a sanitary point of view, even worse than those of Bier-lane. Yet some idea of this latter district may be gathered from the fact that the material—window frames, doors, bricks, planks, rafters, &c., which constitute the twelve or fourteen houses of Red-lion-row, Bier-lane—only realised at auction the sum of £20. This same property produced in rents £100 a year; thus again showing that the worst property is often the most remunerative, and that nothing but an awakening of the public conscience can bring about the purification of these wretched dwellings, where unscrupulous speculators are able to profit by poverty, crime, and vice to extort exorbitant rents.

MR. COOPER FORSTER.

WE much regret to have to announce the death of this well-known and distinguished surgeon, who expired at his residence in Upper Grosvenor-street on Tuesday last from the effects of an attack of enteric fever. Mr. Cooper Forster left London on Jan. 21st for Cannes, where he arrived two days later, and where he stayed until Feb. 16th. He then went to Nice, remaining there four days, and subsequently to Mentone, which latter town he left for home on Feb. 23rd. We understand that when he left London he was in good health, and that on Feb. 13th he wrote a letter to Dr. Wilks from Cannes in which he did not in any way allude to the state of his health. We are informed, however, that on Feb. 3rd or 4th, on returning from a walk of some distance, he felt unwell and vomited, and from that date he gradually became worse. He expressed great dislike to the foreign food and manners, and his appetite not returning, Mr. Forster decided to come home at once, and accomplished the journey from Mentone, one of thirty-six hours, without stopping and without taking other nourishment than a biscuit and a bottle of soda-water. He sent for his old colleague and friend, Dr. Wilks, on the morning after his arrival. Dr. Wilks found him in a state of collapse, with rapid jerky breathing, and a temperature of 103° F., and on the following day called in Dr. Habershon, who also remained in attendance till the end. On Sunday Sir James Paget and Mr. Jonathan Hutchinson met the above-named gentlemen in consultation, but unfortunately Mr. Cooper Forster never rallied, and died from exhaustion on Tuesday, in the sixty-third year of his age. Mr. Cooper Forster, who was President of the College of Surgeons last year, had retired from practice on the very day on which his office as president expired, having that afternoon given orders for the removal of the plate from his door. Mr. Forster, during his stay in the Riviera, had stopped at hotels in the towns he visited. The funeral takes place at Kensal-green to-day (Saturday), leaving Grosvenor-street at 1.30 P.M.

PASTEUR ON HYDROPHOBIA.

THE total number of cases that have now been treated for the prevention of hydrophobia amounts to 350. The first 200 of the cases appear to have been submitted to the preventive inoculations more than two months ago. M. Pasteur asserts that statistics prove that in the majority of cases of hydrophobia in man the disease develops within sixty days of the receipt of the bite of a rabid animal. Consequently he claims that his treatment has been most successful, seeing that not a single case submitted to him, within a reasonable time after the bite, has developed any signs of hydrophobia. We confess that such a conclusion is in every way reasonable: it is reasonable, not so much from the statements as to time, as from the circumstance that so large a number is dealt with. It appears to be inconceivable that of 200 cases of certified bites from rabid dogs not one should be followed by hydrophobia if the treatment be not assigned as the cause of the immunity. We could explain away the immunity if only a few cases were concerned, but hardly, we think, where so large a number of individuals have been bitten more than sixty days ago, and yet without any becoming the subject of hydrophobia. Only one case, which Pasteur unwillingly treated, has succumbed to the disease. This was the case of a girl who had been bitten thirty-seven days before he saw her. Symptoms of the disease appeared ten days later, and, if the case proves anything, it goes to support M. Pasteur's opinion, for the fatal result occurred well within the period above mentioned as the most probable time for the appearance of the disease. In science, and especially in medical

Digitized by Google

science, caution at all points must be exercised; but if the success hitherto achieved by the Professor be maintained and strengthened by the further experience of a few more months, the method will prove a boon to humanity, a gain to science, and justly merits the applause of the human race. M. Pasteur announced his intention last Tuesday of endeavouring to overcome diphtheria by measures similar to those adopted against small-pox and hydrophobia.

A NEW FRAUD IN MILK.

A LETTER which has lately appeared in one of the morning papers states without exaggeration a risk to which the milk-supply of London and other towns is exposed. The Health Exhibition of 1884 made all the world familiar with the ingenious and useful cream separators, in which, by centrifugal action, cream is separated from milk in a few minutes. The process is an excellent one. The cream is, as we have found by recent analyses, of good quality; while the skim-milk—for so we must call the residual milk,—not having had time to undergo the lactic fermentation, is sweet, palatable, and a most valuable food. Considering the high price obtained for the cream, whether as cream or butter, the skim-milk ought to be sold at a very low price, and if properly described, say as "separated milk," it would be a boon in all households, and particularly in poor ones. But the very fact that this skim-milk is so like ordinary milk suggests the possibility of a fraud which is only too likely to be adopted by unscrupulous tradesmen. In the letter to which we have referred, "A Consumer," who evidently knows what he writes about, expresses his belief that this skim-milk is mixed by the vendors with ordinary milk, and, sold at 3*d.* or 3½*d.* per quart, yields a much better profit than genuine milk at 5*d.* The question, then, arises—How is this new fraud (for a fraud on the consumer it obviously is) to be met? Unfortunately the answer is by no means easy. Even if, as "A Consumer" suggests, a raid were made on the stations where such skim-milk was known to be delivered, it would be difficult to prove that it was destined for fraudulent purposes; and once inside the premises of the vendor, who can say what becomes of it? It will perhaps be said that such an admixture can be detected by analysis, as the removal of cream and the addition of water are. But unfortunately the analyst cannot detect any one of these frauds unless they are practised to an extent that a skilful tradesman can easily avoid. Milk is not an article of constant composition, but a variable mixture, and the public analyst is therefore compelled, in order to avoid the risk of injustice, to take as his standard the very poorest milk. The limits at present approved are, as is well known, fat 2·5 per cent., and solids not fat (casein, sugar, and ash) 8·5 per cent. This is a very poor milk indeed, poorer than should be sold except with special description and at a lower price. But down to these limits the wily milkman may water, skim, or add skim-milk, and laugh at the public analyst. We suppose he could be convicted if the inspector saw the water added, but even this seems doubtful, as in the case we have supposed the analyst would be unable to prove adulteration by certificate. The only difficulty in the case arises, as we have on previous occasions pointed out, from the absurd state of the law. After the Food and Drugs Act came into operation it was found that it was powerless to prevent the fraudulent addition of water to spirits. Pure brandy is not pure alcohol, and there was no rule by which any judge could decide how much water brandy might naturally contain. Accordingly a second Act was passed defining the quantity of water to be allowed in brandy and other spirits, and since then there has been no difficulty at all. We hold that in the same manner limits of strength should be assigned by Act of Parliament to milk. The fat should be 3 per cent. and the other solids 9 per cent., and it should be the duty of the vendor not to sell any milk below these limits. The watering or skimming of milk would then be no offence in the eye of the law, and we believe that a considerable strain upon the consciences of many tradesmen would in this way be avoided. The public would then be sure of getting milk of moderately good quality. They would be saved from fraud because they would have no right to expect anything better, and such milk would, in fact, be sufficient for the uses of life. Richer milk would of course be sold in addition, and those who wanted it would be prepared to pay for it.

CRIMINALS SOBERED AND MADDENED, AND MIXED.

THE effect of prison discipline on the minds of convicts is governed by the ordinary laws of nature. Some half-mad brains are sobered and rendered sane, while sound minds give way under the strain of monotonous misery. Unless a proper classification of prisoners be made, and suitable changes are carried out from time to time with a view to avoid evil associations, most disastrous consequences must ensue. The Howard Association, always on the alert for good work, has done well in taking up the subject of classification of convicts in Irish prisons and criminal asylums. We would, however, suggest that, if the best practicable results are to be obtained, it will be essential to keep quite distinct two totally different matters, which seem just now to be in some peril of confusion. The corruption of morals regretted by chaplains is a different matter from the preservation of sane minds and the recovery of the insane desired by doctors. They are things apart, though not necessarily antagonistic. We are not in the least degree disposed to endorse the proposition that it would be better to keep criminals in solitary confinement rather than allow them to associate lest their morals should be further debased. We doubt whether it is ever justifiable to shut a man up with the demon of his own thoughts as his sole companion. Better put him out of his misery at than once than do that. If no better scheme can be devised to send the sobered criminals back to their cells lest they should be corrupted by association we would prefer to let morals run the risk of being debased in convict life. There ought, of course, to be no sane convicts in criminal lunatic asylums, and no lunatics in ordinary prison gangs; but beyond making this separation we do not desire to see the hobby of the advocates of "the separate system" rampant in the prisons of Ireland or elsewhere.

HYALINE DEGENERATION.

Dr. H. STILLING, of Strasburg, has (Virchow's *Archiv*, Bd. 103, Hft. 1) adduced evidence to show that so-called hyaline degeneration may pass on to amyloid degeneration, regarding the former as an early stage of the latter. To test this point it was necessary to show that in recent cases of amyloid degeneration areas of hyaline change are present, and that a transition between the two forms can be traced; and also to establish the fact that hyaline degeneration is met with in those diseases which are known to give rise to waxy degeneration, the hyaline replacing the waxy form in cases where the chronic disease has been cut short by some intercurrent affection. Stilling's researches were conducted upon the spleen, as being the organ which is the earliest to undergo amyloid change; and he employed for the detection of that morbid material, and distinguishing it from hyaline, the iodine and sulphuric acid reaction mainly, various other staining reagents being used for the tissues. He says that he has quite abandoned methyl-violet as a test for waxy disease, because it has the property of reddening colloid, and

Digitized by Google

is not so delicate in the detection of waxy material as iodine is. Details are given of a case of phthisis, where the spleen showed a combination of amyloid and hyaline change; and a number of other cases of acute and chronic disease, where the hyaline product was found, are referred to. Hyaline degeneration in the spleen is found in the walls of the arterioles as well as in the follicles themselves. It commences in the former in the muscular coat, destroying the fibres and their nuclei; not invading the intima, but sometimes involving the adventitia. In the follicle, bands and wedges of the material separate the lymph-corpuscles; and the change is most marked in the centre of the follicle, where it commences by the swelling and transformation of the protoplasm of the cells. Stilling regards it as a deposit, and not as a metamorphosis, and proceeds to point out the striking similarity, not only in appearance but in distribution, that this hyaline change bears to waxy degeneration of the same organ. The diseases in which the hyaline deposit was found were, with two exceptions, of the same class—viz., chronic inflammation of bone and joints, and chronic inflammatory (tubercular) disease of the lungs—as those in which waxy disease occurs; the only distinction being that the hyaline change occurred in cases of shorter duration than the amyloid did. In one case the spleen appeared to be amyloid, but it did not yield the characteristic tests of that degeneration, and was found to be the seat of abundant hyaline changes. It is possible that the involvement of arteries in the change has something to do with its subsequent progress; but an explanation of the difference between the hyaline degeneration of tubercle and that which seems to be only the precursor of amyloid disease is, Stilling thinks, to be found in the lack of vascular supply in tubercle, as compared with that of the regions affected by amyloid degeneration. The degenerative process in a tubercle is thereby arrested at the hyaline stage.

LONDON WATER.

RECENT comments in the London daily press on the purity of London water call for some notice from us, as they are liable to lead to dangerous misconception. It is well known that for years past there has been considerable divergence of opinion between Dr. Frankland, who has analysed the water officially, and Messrs. Crookes, Odling, and Tidy, who have done so on behalf of the water companies. We have no intention of entering into this controversy. Dr. Frankland frequently finds fault with the water, while the other distinguished chemists cannot speak too highly in its praise. Thanks to the constant pressure of public criticism, the water of London has improved very greatly of late years. Not only have more suitable intakes been adopted, but far more attention has been paid to filtration, and, even if not as ideally perfect as the London companies represent, the water-supply of London is now fairly satisfactory. We can never think a sewage-polluted river like the Upper Thames a good water-supply, but we suppose it is for the present the best available, and the companies are certainly now trying to make the best of it. But it would be folly to ignore the risks of such a supply simply because they cannot be accurately measured. The most noxious forms of impurity are not revealed by chemical analysis or even with any approach to certainty by the so-called bacteriological method. The transmission of cholera by water is a question illuminated at present by only a feeble and doubtful light, but it would be madness to ignore the possibility that a water, safe at ordinary times, may become deadly when certain minute organisms float in it. We are safe enough in our water-supply just at present; but should we or ought we to feel safe if cholera raged in the Upper Thames Valley? We might not suffer, but who can be certain that we should not? Gravest of all, to our minds, is the risk, however slight, that if cholera were here some chance unforeseen pollution might introduce the seeds of death into the river in the immediate neighbourhood of the intake of one or more of the great companies. Little can be done before the summer, and we can but hope that that useful sanitary lesson, another cholera epidemic, may be spared us; but we cannot too often repeat that the disease may come with the summer; and if it show its face in the Thames Valley the authorities will be criminal if they do not watch the sources of our water-supply as they have never been watched before. Let them remember the fearful doubt, to say the least, that attached to the water of East London in the last epidemic.

THE QUEEN AND THE MEDICAL PROFESSION.

WE announced last week that Her Majesty had signified her gracious intention of laying the foundation stone of the new building about to be erected for examination purposes on the Thames Embankment. We hail with satisfaction and gratitude this new proof of the interest which the Sovereign takes in the progress of medicine, and in the prosperity of its recognised corporations. There will be a peculiar fitness in the performance of this Royal function, at the present conjuncture, because it will serve to mark with Royal favour the endeavour of the Royal Colleges to achieve by self-help a large measure of that reform which has been denied to them by successive Parliaments. Looking to the history of medicine, it is manifest that the art of healing and the enterprise of its professors have uniformly owed more—far more—to Royal favour than to Parliamentary aid or patronage. The first English writer on Medicine was Richardus Anglicus, who flourished at Oxford about 1230; but contemporary with him, dying in 1241, was Nicolas de Ferueham, and this physician King Henry III. called to his court and made his domestic counsellor, with a large salary. From that time down to the present year of grace the most distinguished physicians and surgeons of the day have almost uniformly been employed by the Sovereign and practised under Royal favour. We all know how much the illustrious Harvey owed to the encouragement extended to him by Charles I., who was personally interested in some of his experiments. Since the days of Linacre, who was successively physician to Henry VII., Henry VIII., Edward VI., and the Princess Mary, and who, with the aid of Cardinal Wolsey and by favour of Henry VIII., in 1518, founded the College of Physicians, that body has enjoyed Royal favour, and now, when its President is the favoured physician of Victoria, Queen of these realms, in 1886, there is an especial interest, which the whole profession will feel, in the august commencement of new and appropriate buildings for the use of the joint Colleges. We trust no pains will be spared to make the occasion worthy of its significance and place in the annals of English Medicine.

FIERCE DOGS.

ANOTHER instance of a horrible set on a child by a dog has been brought before Mr. Newton at the Marylebone Police-court. The dog was the property of a solicitor, and was taken out by his servant, who called on a Mrs. Luck with the dog (a fox terrier). It soon seized her child by the cheek, and was only detached with difficulty, taking a large piece of the flesh, and seizing the elbow of the mother, who rescued it. The solicitor denied his liability, and the magistrate refused to order the dog to be destroyed. He warned the owner (whose liability for compensation in this case is to be tried in another court) that he would be held responsible for the future behaviour of the animal. Dogs that can behave as this one did have a very questionable *raison d'être*. We have scarcely ever read of a more outrageous attack, and the law ought to be more efficient.

CLINICAL SOCIETY OF LONDON.

THE last meeting of this Society was of a remarkably interesting character, from the number of papers read and living specimens shown. For full details of the proceedings reference should be made to the report. Dr. Goodhart read the notes of a case and exhibited the specimen of an extremely rare form of intussusception occurring at the upper part of the jejunum in the very neighbourhood of the duodenum. During life the case appeared to be of the most obscure kind; the stools were never known to contain blood, and actually there was no complete obstruction of the bowels, for the patient continued to pass motions throughout the whole course of the case. The swelling due to the intussusception appears at one time to have been regarded as a movable kidney. Mr. Barker's paper placed on record a remarkable success in abdominal surgery; but some doubt appears to exist as to the precise nature of the case, which the author regarded as originating in volvulus of the upper part of the jejunum. The facts of the case may well be interpreted on Mr. Barker's theory, and it would be exceedingly difficult to prove that his supposition was not the right one. On the other hand, it should not be forgotten that minute ulcerations of the duodenum and other parts of the intestine may occur without the examiner being able, even after death, to discover the perforation. The rapid improvement that followed the operation of abdominal section, though in favour of the author's interpretation, might also be explained on the assumption of a slight extravasation of intestinal contents. The intense form of peritonitis, its wide extent and mode of onset, are at least as consistent with the notion of perforation as with that of volvulus, even though it be borne in mind that several of the recorded cases collected by Mr. Treves of volvulus of the region in question were accompanied by severe peritonitis. In Mr. Barker's case the intestinal obstruction appears to have been complete, and if the volvulus were the cause of this, it seems unusual that the bowel below the obstructed portion should not have been collapsed. On this feature, however, there must rest some doubt. It is possible that the absence of collapse below the seat of obstruction might have been due to peritonitis, causing tympanites, though it may be difficult to realise that a bowel collapsed in the first instance should subsequently become inflated by the action of a serous inflammation.

THE BRAIN SURGERY OF THE STONE AGE.

MR. VICTOR HORSLEY gave an interesting lecture on Wednesday last in the Botanical Theatre of University College, at a meeting of the Medical Society of that institution. After showing how the earliest implements used for cutting purposes were made either of shell or stone, and having briefly described the mode in which the Bronze age succeeded the Stone age through the utilisation of copper alloyed with tin and was followed by the iron and steel periods, Mr. Horsley discussed the evidence that existed as to the extent in which brain surgery existed amongst the inhabitants of the caves and villages of the Stone epoch. By means of the lime-light he showed photographs of skulls which had various kinds of holes. Some of these perforations had admittedly been produced by the pick-axe of the finder. The skulls were from "finds" chiefly in the lower and middle thirds of France, and being found buried beneath the floor of caves side by side with stone implements, the inference was drawn that they belonged to the Stone epoch. Other holes in the skulls were either made soon after death for purposes of embalming, or were else the witnesses of an unsuccessful surgical operation. There was again a third class of holes which were clearly the result of primitive kinds of trephining; for there were evidences in the smooth and rounded character of the edges, the presence of hard osteophytes and even of prolonged suppuration in the form of osteoporotic material, that some of the perforations had been made during life, and the patient had lived long after their production. Most of these specimens belonged to individuals who had been young at the time of operation. The majority of the holes were situate in the parietal region, and, as Mr. Horsley showed, over Ferrier's "motor area." The author also believed that such trephinings had been done for cases of some kind of epilepsy. Altogether the lecture was very interesting, and afforded scope for much ingenious hypothesis, of which Mr. Horsley freely availed himself.

THE CEREMONY ON THE THAMES EMBANKMENT.

THE hour at which Her Majesty the Queen will graciously lay the foundation stone of the new Examination Hall on the Embankment, on Wednesday, March 24th, will be at or about 11 o'clock A.M. We believe that the space at the disposal of the two Colleges on this occasion is limited. Indeed, a circular has been issued to the Fellows of the College of Surgeons requesting them to state whether they wish their names to be included in the list of Fellows desirous of being present, from which list the places available for witnessing the ceremony will be assigned by drawing lots. The Fellows of the College of Physicians, not being so numerous a body, will, we believe, have the opportunity of being present should they wish. We fear, however, from the above intimation, that the space will be very limited indeed, and that large numbers of practitioners, to say nothing of students, will be greatly disappointed at not being able to attend on so important an occasion, when Her Majesty bestows a high and rare honour on the medical profession. We understand that only some thirty or forty of the gentler sex will be enabled to be present to witness this gracious act of the first lady of the land.

THE SANITARY CONDITION OF EAST GREENWICH.

AT an inquest held in the board-room of the Greenwich Union, on Feb. 26th, by Mr. E. Arundel Carttar, several facts transpired which pointed to the defective sanitary state of the neighbourhood. The subject of the inquiry was the cause of death in the case of a young woman named Gibson, who died nine days after her first confinement. The friends of the deceased were disposed to attribute the fatal illness to carelessness on the part of the doctor in charge of the patient, inasmuch as they alleged that the unfortunate woman succumbed to inflammation of the lungs consequent on catching cold through the bedclothes getting wet whilst a vaginal injection was being used. The case illustrates well the readiness with which an erroneous conclusion may be arrived at, and how ignorant the ordinary mind is of the care which is required in selecting the premisses for an argument which are true in themselves. In the first place, the injection before mentioned was employed because the patient was feverish and had abdominal pain, and because the lochia had become offensive; in fact, there was quite sufficient evidence to warrant the medical man in assuming the patient had puerperal fever; and, secondly, it was exceedingly improbable that the temporary dampness of the bed would of itself induce acute pneumonia. The post-mortem examination revealed a small rent in the perineum (the late stages of the labour had been unusually rapid), a small portion of placenta adherent to the uterine wall, and acute general peritonitis, most marked in the pelvic region. The questions then occur—How did the infection take place? Was it autogenetic? Was it communicated by the doctor or nurse? Or had the sanitary conditions of the house and neighbour-

Digitized by Google

hood anything to do with its causation? In support of the latter proposition, it may be stated that the same tank supplied the watercloset and the house generally, including drinking-water for the residents. The apparatus intended to regulate the flushing of the closet was out of repair, and had been so for some time. There was an accumulation of excreta in the pan of the closet, which was only periodically and partially removed by throwing slops down. The roadway in front of the house was not paved, not even macadamised, and in this condition it is said to have been since the houses were built some two years since. Furthermore, the houses are situate on marshy soil at or below the level of the Thames bed. It was given in evidence at the inquest that diphtheria had been rife in the locality—in such severity, in fact, as to occasion a special investigation by the authorities. No wonder, then, that under such circumstances puerperal fever should arise and assume a grade of fatal severity. Although the actual source of the disease in the case under consideration was not traced, enough facts were adduced to lead the jury to entirely exonerate the medical man from all blame, and to point out the necessity for a complete examination into the dangers threatening the public health of the district. At the same time, it is a matter of paramount importance that it should be generally known that no person who has recently been in attendance on a case of infectious or contagious disease—such as puerperal fever, erysipelas, or diphtheria—is justified in entering the chamber of a parturient woman; and medical men cannot be too careful as regards their direct personal responsibility, nor too anxious in shielding their patients from the harm that may arise from the carelessness or ignorance of others.

DENSITY AND MORTALITY.

THE late Dr. William Farr was one of the first to call serious attention to the constant relation between density and mortality. The arbitrary boundaries, however, of our large English towns place the greatest difficulties in the way of calculating, even approximately, the relative density of town populations, measured by the number of resident inhabitants per acre of the town areas. The English census, moreover, gives no information from which more trustworthy statistics of density can be calculated. The Scotch census, however, gives not only the number of apartments in each tenement, but also the number of inhabitants found resident therein. These facts supply the basis for far more trustworthy statistics of density than any that can be obtained for England. Dr. James B. Russell has recently turned these facts to very good account in a report he has recently issued on the Vital Statistics of the City of Glasgow. Dr. Russell remarks that "if we could ascertain the cubic contents of every dwelling-house or room we should get to the heart of this element of density in the physical circumstances of the inhabitants of towns." The information he has been able to obtain from the Scotch Census Report, however, goes a long way towards supplying really trustworthy density figures. It appears from Dr. Russell's interesting table that there is a very close relation between mortality and the number of inhabitants per inhabited room. This table gives the mean annual death-rate in the ten years 1871-80, the persons per acre of area, the rooms per tenement, the persons per room, and the percentage of population living in tenements of one room and of five rooms and upwards, with the average number of persons per tenement of these two classes, in each of the eight principal towns of Scotland. These figures prove conclusively that, whereas mortality bears no very constant relation to density of population measured imperfectly by persons per acre, its relation to density measured by persons per inhabited room is very clearly marked. It appears, for instance, that the number of persons per room was equal to 1·87 in Dundee, 1·91 in Greenock, 1·98 in Paisley, and 2·05 in Glasgow; and, further, that the mean death-rate rose steadily in the same order to 25·7, 27·4, 27·8, and 28·6 per 1000 respectively in these four towns. In the other four of the eight towns the mean death-rate ranged from 21·7 in Aberdeen to 23·2 in Edinburgh; the persons per room in these four towns ranged, but not in quite the same order, from 1·31 to 1·67. It is probable that these slight inequalities in the parallelism between mortality and density, measured by the number of persons per inhabited room, would disappear if account could be taken of the size of the rooms. The value of these statistics of density of population in the Scotch towns emphasises the desirability for urging that at the next English census measures should be taken for obtaining information relating to the housing of the people similar to that which was obtained at the last census for Scotland.

THE REGULATION OF SUB-LET HOUSES.

IN a recent monthly report, Dr. Dudfield, medical officer of health for Kensington, draws attention to a decision which may affect the several codes of bye-laws which have during the past few years been drawn up as to houses let in lodgings. One clause of the model code issued by the Local Government Board gives power to the authority to summon the landlord to attend at the office of the authority to "supply the information necessary for the registration of the house," and to give certain particulars as to the total number of rooms, the number occupied by members of more than one family or let in lodgings, the manner of use of each room, and the number, age, and sex of each of the occupants of the several rooms used for sleeping. A certain landlord having failed to appear, he was summoned for neglecting to comply with this first bye-law, but his counsel contended that the regulation was *ultra vires*, for although the authority had power to make regulations for fixing the number of persons who may lawfully occupy the house, &c., yet they had, under the Act, no power to compel the attendance of a landlord at their offices. Sir James Ingham sustained the objection of the defendant, but at the same time he observed that the question was too important to be settled by him, and that a case should be stated for a superior court. We trust that this advice may be acted upon in order that the matter may be finally settled. But in the meantime we may point out that Dr. Dudfield has, in his district, always felt that the best way of supplying such information as the authority could act on, was to direct the several sanitary inspectors to obtain the necessary details as the result of an actual inspection of the premises concerned, and he looks with but little concern to any adverse final decision which may be arrived at. In short, if the clause be found to be illegally imposed on landlords, Dr. Dudfield thinks that an even more efficient method of arriving at the end in view is still available.

PUBLIC HEALTH IN VICTORIA.

THE last report of the Central Board of Health of Victoria contains considerable evidence of sanitary progress in the colony. Such matters as food adulteration, infant life protection, calf-lymph vaccination, and the provision of sanatoria for infectious diseases are receiving much attention, and a proposal has been made to the Government to appoint at least one inspecting medical officer on the same lines as the appointments connected with the Local Government Board at home. Improvements are also proposed at the quarantine station, but the record of work in connexion with the quarantine laws can hardly be regarded as affording a happy illustration of that system. Thus, small-pox is quarantined in Victoria, and the healthy as

Digitized by Google

well as the sick are subjected to that process. A single case of small-pox arrived in the R.M.S. *Rome*, and all the passengers were quarantined, the detention apparently lasting for at least fourteen days. The result was unfortunate, for we read that shortly after the release of the vessel a case occurred at Carlton, and then a number of other cases occurred in and around Melbourne, and a few in country districts. Had the colony, after isolating the solitary sick person and resorting to such disinfection as was practicable, trusted to vaccination as a protection, the probability is that the disease would not have spread, and the vexatious detention, which the result shows to have been useless in so far as preventing the extension of the disease is concerned, would have been avoided. The adoption of the true measures for the prevention of infectious diseases is, we believe, always more or less hindered by resort to the old quarantine system, and nowhere has its abandonment been followed by such fortunate circumstances, as regards the promotion of public health, as in the mother country.

WHAT WILL THE BOARD SAY?

"MR. CHILDERS informed Mr. Thorold Rogers that the Metropolitan Board of Works were charged with carrying out the recommendations of the Royal Commission on the Pollution of the Thames, and he had called on the Board to say what they had done in the matter." This is satisfactory as far as it goes. The Board, which created the nuisance, and which for so many years has ignored the condition upon which power was entrusted to it, ought, after its signal defeat before the Royal Commission, to have taken instant and vigorous action to remedy the proved evil, and to avert the danger to which during the coming summer the metropolis will be exposed. We can only hope that a prompt and satisfactory answer can be made to the pertinent inquiry of the Home Secretary. But we cannot pretend to be sanguine. As far as we know, all that has been done is the carrying out of some experiments on precipitation at Crossness, the nature of which has not, we believe, been published, and a disinfection of the sewage, which is as illusory as it is expensive. We know what the answer ought to be. It ought to be that all known schemes had been carefully studied, the expense of each computed, and some one or two chemical processes selected which could at the shortest possible notice be adopted at the present outfalls, and that in addition one or more alternative schemes had been prepared for taking the sewage lower down the river and there purifying it, as the Royal Commissioners advised. The public ought to know as soon as possible what the Board has and has not done, and we trust Mr. Thorold Rogers will renew his question at no distant day.

EXCESSIVE PAROCHIAL ECONOMY.

THE frugality of parochial guardians, as a class, has by this time become proverbial. The tendency in itself is in the right direction, and we have nothing to say against it as a generally safe guide for practice. It may, however, be too implicitly followed, and of this we are reminded by a recent example. The Honiton board have lately had to consider the re-election of their medical officers, and are disposed to reduce the present salaries of these gentlemen before admitting them to a further term of office. We congratulate the board on the moderation with which they have recommended the adoption of this step. At the same time we must admit that their proposal itself does not seem to us equally reasonable. The prevailing commercial and agricultural depression is said to necessitate the proposed reduction. It has also been stated that the medical officers have provisions at a cheaper rate now than formerly; and, further, that the abolition of tolls has diminished their expenditure. We do not wish by any means to disregard the present unfortunate condition of trade, or to discountenance needful and just economy; still we cannot, on examination, accept the conclusion of their arguments. It would surprise us very much to learn that the salaries in question will bear diminution, even in consideration of the circumstances above mentioned. There seems also to be good reason to doubt the reality of the supposed profit on expenses which these hard times are said to have introduced. Road expenses continue, though the toll-gate is no longer a means of exacting them. Depression in agriculture, again, affects the payment of medical bills in a degree probably quite equal to its effect on the incomes of landlords, farmers, and the county population in general. The medical officers of Honiton can, of course, best judge for themselves as to the bearing of the proposed reduction on their own finances. We do not consider that a satisfactory objection to the present rate of remuneration has been brought forward, and the Board of Guardians will, we hope, see that in their proposal rather too much has been made of the necessitous condition of the country.

DELAY AND DISEASE AT TOULON.

THE Mayor of Toulon, the Prefect of the Var, and the engineer of the town of Toulon have been on a deputation to Paris. They had interviews with M. de Freycinet, President of the Council of Ministers, with the Minister of War, the Minister of Commerce, and the Minister of Public Works. They pleaded the absolute necessity of at once carrying out sanitary works to prevent the recurrence of cholera and other epidemic diseases in the great maritime fortress they represented. But, in answer to this most urgent and justifiable request, they were informed that the Budget Commission had decided that no large and new public works should be undertaken before the year 1888, As the project for the draining &c. of Toulon will, it is estimated, cost £48,000, it enters the category of new and important public works, and therefore cannot be sanctioned. The same technical objection could not, however, be raised to the dredging and improvement of that portion of the port assigned to trading vessels. It is probable that harbour works of this description, involving an outlay of £8000, will be undertaken this year; but that little or nothing will be done to remove the numerous sources of infection which render the town of Toulon a disgrace to modern civilisation. Abandoning for the moment the project of drainage for the entire town, the Mayor of Toulon besought M. de Freycinet to facilitate some temporary measures. such as the roofing over of certain ditches which serve as sewers, and notably the ditch that receives the drainage of the town slaughterhouse. M. de Freycinet promised to support a vote of credit for this object, and admitted that the State should contribute half the sum, as Toulon is an arsenal town with but small resources of its own. Thus the matter stands. When we consider the insanitary condition of Toulon, its high death-rate, and the fearful havoc created by the cholera epidemic, we are compelled to urge that the decision of the Budget Commission should not stand in the way of saving innumerable and valuable lives. Typhoid is endemic in Toulon, small-pox is now exceptionally prevalent, and military and naval recruits must be quartered on the summit of the mountains, or in forts built out at sea, to prevent the outburst of epidemics in the regiments. To check extravagant public works, many of them mere embellishments of an ornamental description, is probably a financial necessity in France; but where public health is concerned it has been demonstrated over and over again that prudent expenditure is the truest economy.

THE QUEEN AND THE ICE ACCIDENT AT WINDSOR.

WE are glad to hear that the Queen has manifested great concern with respect to the fatal accident that has recently occurred on the ponds adjoining Cumberland Lodge, Windsor Park. The whole administration and condition of this Royal domain demands immediate inquiry. To our knowledge, complaints were recently made with regard to the absence of adequate means for saving life at the Virginia Water. It was suggested wheels might be affixed to a flat-bottomed boat, so that it might be pushed forward to rescue anyone falling in the water. Should the ice break, oars could be substituted for the poles employed in punting the boat on the ice. This simple and inexpensive request was, however, cast aside, though precisely two hours after the letter containing this petition had been forwarded to the competent authority a man who was skating fell into the water in one of the deepest parts of the lake. Luckily he was a good swimmer, and succeeded in saving his life. Perhaps if he had been drowned the authorities would have seen the necessity of taking some measure of precaution. This is in keeping with several other grievances for which Windsor and its neighbourhood has become too notorious. Under such circumstances pressure emanating from the highest quarters and supported by public opinion is needed, and will not, we are convinced, be withheld.

THE DARENTH SMALL-POX CAMP.

AN important decision was last Tuesday given in the case of Fleet *v.* the Metropolitan Asylums Board. This was an appeal by Mr. Fleet, a resident and owner of property in the neighbourhood of the Camp, against a previous refusal to grant an injunction to restrain the defendants from continuing the use of the Camp for cases of small-pox. The appeal was heard before Lord Justice Cotton, Lord Justice Bowen, and Lord Justice Fry, and each of the learned judges agreed that the appeal must be dismissed. Lord Justice Cotton, in delivering judgment, pointed out that "the legal question to be decided was whether there was an appreciable injury to the healthiness of the plaintiff's property. The plaintiff must make out that there was real danger, otherwise, however much they might feel the hospital to be an annoyance, they could not get an injunction." The only important question raised was whether the hospital could be a source of danger through infection aerially conveyed, but on this point the "expert" evidence was so contradictory that the allegation was held to be not proven. Lord Justice Bowen's remarks deserve further consideration than we fear they are likely to receive. He said, "a court of justice was not a fit place for the exercise of inductive logic. Life was short, and it was impossible to give endless time to the examinations of a scientific theory for the benefit of one set of litigants. No doubt sooner or later science would discover and assert with confidence whether infection does blow across the hills and valleys, but he declined to be driven into the scientific question or to forecast the future." With the exception of Mr. Power's investigations concerning the Fulham Hospital and those of a few health officers whose districts contain or are in proximity to small-pox hospitals, the whole question has been relegated to the lawyers. There has as yet been no other thought about the whole matter than whether one or another person has suffered pecuniary loss; the loss of life, which has undoubtedly occurred in the neighbourhood of small-pox hospitals, and which is far more important than loss of money, has not been deemed of sufficient consequence to warrant a complete inquiry by either of the hospital-providing boards. But even if the subject be considered purely from the monetary point of view there is no question that the necessary investigation could have been conducted at a mere fraction of the cost to which the London ratepayers have been put through the inaction of these authorities. We would commend Lord Justice Bowen's remarks to their consideration.

PITY THE POOR PEERS!

ACCORDING to the Earl of Limerick, who seemed to speak feelingly, the Lords of Parliament assembled in their own Chamber are in a pitiful predicament. Their lordships' feet are in a cold bath, while their "lordships' heads are swimming in an atmosphere of a very different kind." Now, as the Earl warned his brother peers, with practical truthfulness, this state of things is of benefit to no one except their lordships' doctors. The Lord Chancellor was able to corroborate the statement of the noble Earl by the evidence of his own experience at the bar of the House. He (Lord Herschell) had spent much time in that building and had never returned home without a headache, which he had never experienced in his practice before other tribunals. Their lordships laughed when the advocate who had pleaded before them, now their chairman, made this avowal. There was just a little tremulous irony in their merriment, which seemed to suggest that perhaps a part of the headache might be due to the tribunal rather than to the building in which it sat. However this may be, we heartily pity the poor peers with their feet in a cold bath and their heads swimming, and we wish them well out of their troubles, even though their lordships' gain should be our loss. There is this great practical difficulty about the ventilation of the two Houses of Parliament: The chambers must needs be large enough to accommodate all those who are entitled to assemble within them, although it rarely happens that anything like the full number is reached. The buildings must be kept warm, and there must not be draughts. We confess that it has always appeared to us a mistake to place edifices so large as those required for the accommodation of Parliament under a complicated system of artificial heating. It would be better and easier to subdivide the work considerably, and enforce the maintenance of a common temperature on the officials responsible for the heating and ventilating of both Houses. The air supplied to the chambers and corridors is deprived of its freshness before it is allowed to mix with the contained atmosphere, and it is actually impure air the members of the two Houses inspire. Only those who have spent many consecutive hours, night after night some four days a week through long sessions, know how terrible the infliction actually is. Not only the peers, but the members of the lower House of Parliament deserve the pitiful sympathy of their fellow-men in relation to their sad experience in this matter of deficient or defective ventilation.

THE EVERTON MURDER.

ON the 15th ult., Michael Lavelle, aged sixteen, was tried before Mr. Justice Day at the recent assizes held in Liverpool, for the wilful murder of a man named Maxwell Kirkpatrick, by striking him behind the right ear with a wooden roller, such as is used in timber-yards. It was noticed that the prisoner held the weapon in both hands. The deceased was knocked down and rendered insensible by the blow, but in about five minutes he recovered sufficiently to be able to walk home with assistance, the man who aided him noticing that blood was flowing from his right ear. After reaching home the deceased called upon a medical man, who advised him to return at once and go to bed. He did so, and when visited by the doctor shortly afterwards was found to have become unconscious, continuing in that state until his death, which took place on the following morning, between sixteen and seventeen hours after receiving the fatal blow

Digitized by Google

At the trial, Dr. Ellis, the deceased's medical attendant, stated that there was no external evidence of fracture, nor was there any wound. He remained with deceased during the whole time of his illness, with the exception of a brief interval, and subsequently made a post-mortem examination. It was then found that the inner table of the temporal bone was fractured to the extent of three inches, and that the cause of death was compression of the brain, there being a clot between it and the membranes at the seat of the injury. The prisoner was found guilty, with a strong recommendation to mercy, and sentenced to death. An official communication has, however, since been received at the gaol in which he is confined to the effect that the execution will not take place—presumably on account of the youth of the prisoner. It would be interesting to know whether any consultation was held, and the question of an operation considered. It is possible, seeing how the locality of the injury was indicated by the hæmorrhage from the right ear, that the case might have been a suitable one for trephining. Assuming the facts as above stated to be correct, the removal of the clot might have been successfully accomplished, and if there were no other fatal injury the deceased's life might have been saved. It is most important in all cases involving so serious a charge as murder or manslaughter that the advice of a second practitioner should be sought, and that the post-mortem examination should be made in the presence of some surgeon skilled in medico-legal investigation. It is possible that this was done in Lavelle's case; but it would be more satisfactory to have the matter placed beyond doubt. The published reports of the case contain no record of such proceeding.

EXPERIMENTAL AORTIC REGURGITATION.

BY lacerating the aortic valves by the aid of instruments passed into the aorta through the carotid artery, M. François Franck has been able to study the immediate and remote effects of this experimental form of aortic regurgitation. In some cases death supervened rapidly, especially when the heart was diseased previously. If the animal survived, the arterial tension, at first lowered, mounts again, and the heart becomes hypertrophied and its vascular activity is increased. According to M. Franck the excessive work of the heart is not to be solely attributed to the aortic reflux, but also to an irritation of the sigmoid region, on the ground that slight lesions or a superficial irritation of this region give rise to similar hypertrophy. He also explains the danger of syncope of cases of aortic incompetence by the excessive and prolonged distension of the cardiac cavities, as well as by the depression of the arterial tension of the brain.

HEARING, READING, AND THINKING.

THE interesting address of Mr. Goschen to the students of the London Society for the Extension of University Teaching gathered together from twenty-five or more centres of the metropolis, with the Lord Mayor in the chair, was an embodiment in a general way of the pithy Baconian principle: "Reading makes a full man, conversation a ready man, and writing an exact man." It is by a combination of these three that all-round intellectualism is to be gained. Mr. Goschen defined a lecturer as a condensing machine: "He condenses for the benefit of his audience the result of his own reading." But condensation of intellectual food means more or less indigestibility. Thus, teaching by lecture falls short of that fulness of illustration which is necessary to the entire grasp of the subject. It is a far better training for the lecturer than his audience. The colloquial method of teaching tells more to the advantage of the hearers than the oratorical. Students of medicine who estimate the advantage to themselves of the set lecture compared with the colloquial demonstration on such subjects as anatomy, physiology, or pathology, or, still more, on practical medicine and surgery, will form a correct idea as to which is the better method of teaching. Within the past quarter of a century a great change has come over our medical schools, the demonstrative and colloquial teaching replacing the oratorical. But whatever the method, it is, after all, the close and unwearied application of the student himself that gives the real mental training, and the more difficult the subject to the individual the better the training. When the present Bishop of London, at the time he was Head Master of Rugby, was examined before the Royal Commission on Public Schools, he gave as his reason for retaining Greek as an essential element in the highest education that of all subjects it was the most difficult, and therefore formed the best mental training. Every student has the equivalent of Greek in the subject which is the most difficult for him to acquire. If he masters this, he need not despair of the rest; and when in after-life new and complex problems present themselves in the practice of his profession, the training which the mastery of his most difficult subject afforded him will best fit his mind to solve these.

GRANULAR MATTER AND DILATANCY.

A PRINCIPLE of granular matter, named "dilatancy," having a very wide application, formed the subject of an interesting lecture at the Royal Institution by Prof. Osborne Reynolds. It can be easily understood that the aggregate interstitial space in a pile of shot may undergo considerable variations in amount between a maximum and minimum. A convenient mode of measuring the variation in the amount of interstitial space was suggested by Prof. Reynolds in the form of an indiarubber-bag containing sand, in which the interstitial space is occupied by water; the variations in the amount of water could easily be determined by a kind of manometer in communication with the interior of the indiarubber bag. If the bag be filled with water and sand so that the water was at a certain height in the manometer it was found that certain amounts and directions of pressure on the bag caused a fall in the height of the water in the projecting tube, evidently showing that the interstitial space in the bag had become augmented. It is well known that in walking on certain sands at the seashore the parts around each foot impression become dry-looking, whilst that under the foot gets wetter than it was; Prof. Roberts perceives in this phenomenon an illustration of the dilatancy of granular matter.

SANITARY INSPECTION IN WATERFORD.

SOME difficulty has arisen in Waterford in connexion with payment for medical services under the Labourers Act. The work in question consists in the sanitary inspection of newly-erected cottages. Its amount varies considerably in accordance with the plan adopted in building, and doubtless with the distance to be traversed by the inspector in different cases. We learn, for example, that in one district there are several cottages under the same roof, a matter which must somewhat facilitate their examination. A more distinct plan of structure necessarily implies a greater outlay of time and energy. There seems to be no fixed tariff in Waterford or its neighbourhood for the settlement of such professional claims, and it is evidently very desirable that some common agreement on this head should be brought about. We are informed that in Youghal £1 was the fee allowed for examination of a cottage, and in Drogheda 5*s*. The practitioners of Waterford have adopted the mean between these sums (10*s*.) as their profes-

Digitized by Google

sional charge, while the union board of that town are divided between the latter sum and the Drogheda minimum, the majority being in favour of allowing the lesser fee. The inspection of a house, even a cottage (which, be it remembered, includes in the groundwork the most important area from a sanitary point of view) is an occupation which not only takes up a considerable amount of time, but calls for skill of a superior order for its correct performance. In many cases 10*s.* would not be an excessive fee, and it might not, indeed, in some cases sufficiently pay the inspector. A maximum of 5*s.*, except in consideration of steady employment in this way and of local facilities as to distance and the like, we should consider too low. From want of an intimate knowledge of the special circumstances, we cannot enter at length into the dispute between Waterford and its sanitary advisers, but there is much to be said, in our opinion, for the retention of the rate of payment requested by the latter, while, on the other hand, some reduction may very well be made where the cottages are contiguous or are under the same roof.

THE SALE OF POISONS.

WE are glad to find that the question of the sale of poisons is likely to occupy the attention of the Legislature at no distant date. On the 26th ult., in the House of Lords, the Earl of Milltown asked what steps it was proposed to take in the matter, and reminded the Government that last session a Bill dealing with the subject was introduced in the House. He alluded to circumstances which had recently occurred as showing the extraordinary facility with which persons absolutely unknown to vendors might obtain the most deadly poisons. Earl Spencer stated that the question was under consideration, and he hoped in a few days to be in a position to make a definite statement as to the intentions of the Government.

A CONSTANTINOPLE PHYSICIAN ON HOSPITAL ADMINISTRATION.

DR. PARDO, of Constantinople, writing in the *Gazette Médicale d'Orient*, complains of the condition of the hospitals connected with the various powers represented at the capital of the Ottoman empire. Reports of hospitals in other civilised countries, though they by no means always describe matters as being in a fully satisfactory condition, still serve to expose defects and to let the light of public opinion shine upon the condition of the buildings and the conduct of the officials, in a way which is impossible in an Oriental city. He hints that appointments to the staff ought always to be made by *concours*, and a strict system of control and inspection instituted and maintained. As to the *concours*, however, he does not seem to be hopeful about its feasibility in consequence of the difficulty of obtaining a competent and impartial jury. Again he ventures an opinion that "the practitioner—and all are practitioners here—should not perform operations except where absolutely necessary and of acknowledged utility, leaving bold enterprises to the great masters of the art, who possess all the requisite qualities, immense knowledge, and ability, which justify them in assuming responsibility." Two cases of hazardous operations of which he was witness are mentioned: one could not even be completed for lack of instruments and of intellectual resource on the part of the operator. The hospitals ought to be built, furnished, and regulated according to all the most improved methods, or there should be no hospitals at all (!); a double set of buildings being required, so that all in turn may lie empty, and be disinfected for six months every year. Dr. Pardo once communicated his views to an ambassador whose hospital he was attending, and was answered somewhat sarcastically by an intimation that the only way to achieve the desired result would be for the ambassador to give up his two palaces for the purpose, to which the doctor retorted: "I would not refuse your excellency if they were in the best hygienic condition, but they leave much to be desired in that respect." With regard to lunatic asylums, if the picture Dr. Pardo gives of what he has seen is not "ancient history," a very searching inquiry should be made by trustworthy inspectors as to the conduct of these establishments.

THE BIRMINGHAM MEDICAL SCHOOL.

FAITHFUL to the motto on their municipal arms, "Forward," our brethren in the Midlands are making great and successful strides in the reorganisation of their medical school, which has attained an unprecedented degree of prosperity. The increasing number of students has not unnaturally been influenced by the powerful attraction of the General and Queen's Hospitals united for purposes of instruction under a clinical board, over which Sir James Sawyer presides. The pupils also have access to the wards of the spacious Borough Asylum, the superintendent of which, Mr. E. B. Whitcombe, has lately been appointed clinical lecturer in Lunacy and Mental Diseases in connexion with Queen's College. Soon after Mason Science College was established, Mr. Oliver Pemberton projected a scheme for its alliance, in the interests of medical education, with the old Queen's College. The plan won general assent, and has now been in successful working for some years. In chemistry and physiology, botany and physics, the Birmingham medical students have at their disposal the great resources of Mason College; while anatomy and physiology, medicine and surgery, materia medica, pathology, diseases of women, and ophthalmology are taught at Queen's College. To Dr. Alfred H. Carter belongs the credit of having initiated a complete reorganisation of the anatomical department, which is now in a high state of efficiency under the direction of Professor Bertram Windle, with Dr. Hogben as his principal assistant, and Dr. Foxwell, Mr. Haslam, and Mr. Jordan Lloyd as demonstrators. The Anatomical Museum has been enriched and rearranged at great expense and labour; and the same work is now in hand for the materia medica and the pathological departments. It is only just to add that the large class of students have shown themselves worthy of the increased advantages placed at their disposal, by steady and very good work. Their junior medical society at Queen's College is a model of organisation and useful activity.

INDUBITABLE CONGENITAL TUBERCULOSIS.

AN eight months' fœtus was taken from a cow, the subject of advanced tuberculosis, by Dr. Johne. The placenta and uterus were free from tuberculous lesions, but in the lower lobe of the right lung a nodule the size of a pea was detected containing four caseous centres. The bronchial glands were congested and also tuberculous. The liver contained numerous grey granulations. Microscopically the tubercular structure was confirmed; masses of epithelioid cells with giant corpuscles containing tubercular bacilli were discovered.

FALSE CERTIFICATE OF A SUICIDE'S DEATH.

FALSIFICATION of death certificates, even when prompted by a wish to avoid wounding the feelings of relatives, is a very serious matter, in foreign countries as much so as here. Two St. Petersburg practitioners who attended a girl who had poisoned herself with opium yielded to the entreaties of the parents and gave a certificate that the cause of death was "heart disease," and so of course no difficulty arose about the burial. The case, however, he

Digitized by Google

recently come before the law courts, and in spite of the defence set up that the certificate was not an official document, but intended solely for the use of the statistical department, the two doctors were condemned to two days' imprisonment and a fine of ten roubles (£1).

A NEW journal dealing with forensic medicine, criminal anthropology, and law is being brought out in Lyons under the title of *Archives de l'Anthropologie Criminelle et des Sciences Pénales.* The editors are MM. A. Lacassagne, Professor of Forensic Medicine; R. Garraud, Professor of Criminal Law; Henry Coutagne, Chef de Travaux of Forensic Medicine; with Dr. A. Bournet as secretary. The journal will appear six times a year. The first number contains the following articles:—1. Report on Criminal Law and Penal Sociology, by M. Garraud. 2. Practice of Judicial Medicine in France, by M. H. Coutagne. 3. Indecent Assaults on Little Girls, by M. Lacassagne; also a critical review of foreign works by M. Bournet, and varieties.

ON Tuesday evening Sir Joseph Fayrer gave a lecture at Exeter Hall to the members of the Young Men's Christian Association. The subject of the address was "The Natural History, Habits and Diffusion of Cholera, and what might be done to prevent or mitigate it." The lecture was attentively listened to, and appeared to be much appreciated by an intelligent audience. Lord Fortescue proposed and Sir H. Pitman seconded a vote of thanks to Sir Joseph for his excellent discourse.

IT is stated that there is no foundation for the rumour recently current to the effect that the Government have resolved to accept Mr. Stansfeld's motion for the 16th inst. for the repeal of the Contagious Diseases Acts. The subject has not yet been before them. Mr. Stansfeld has obtained first place on the date mentioned, and will proceed with his motion in due course.

ON the 1st inst. the death occurred of Dr. Daniel Elias of Southport. The deceased, who was about fifty years of age, had been in practice in Southport for twenty-eight years, and was well known and highly respected by all classes. He was one of the honorary consulting medical officers of the Southport Infirmary, but resigned the post a few days prior to his death.

THE corner stone of the new College Buildings of the London Hospital will be laid on Tuesday next, March 9th, at 3 P.M. The new Home for Nurses in connexion with the hospital will be open for inspection during the afternoon.

MR. EDWARD FREEMAN, D.C.L., has consented to allow himself to be nominated for the office of Lord Rector of Edinburgh University in November next.

THE next annual meeting of the Italian Ophthalmological Association is to be held at Genoa in September.

THE DEAD DOGS.—At the meeting of the Enfield Local Board on the 25th ult., the medical officer reported that a large quantity of decomposed dogs was placed in heaps upon a farm in the district. A member of the board stated that the milk in his dairy was tainted whenever the heaps were turned over or moved, and that it was only lately that disinfectants had been used. About 750 bodies per week are sent down, but as many as 1200 have been received. A committee was appointed to be present at the next turning over of the heaps.

Pharmacology and Therapeutics.

HYPNONE.

IN a recent number of the *Bulletin Général de Thérapeutique*, Dr. Dujardin-Beaumetz and Dr. G. Bardet give an account of the physiological action and therapeutic uses of a substance to which they propose to apply the term "hypnone." It has many names, the best known being acetophenon; but although they may be useful as indicating its chemical composition, they are ill-adapted for the requirements of the practical physician. It is made by distilling together a mixture of benzoate and acetate of lime. At ordinary temperatures it is a clear, colourless liquid; but on exposure to even a moderate degree of cold it is converted into a mass of beautiful crystals. It is simply a laboratory produce, and as yet has not been manufactured for commercial purposes. Its price is somewhat high; but as the dose is small this is a matter of little importance. It has a most persistent characteristic odour, so that few patients would care to take it unless enclosed in capsules. Its physiological action is very marked, and there is reason to suppose that we are in possession of a hypnotic only second to urethan. In cases of simple insomnia, unattended with pain, its action is marvellously prompt, and there are absolutely no after-symptoms, such as nausea, headache, or constipation, which so frequently follow the administration of opium or morphia. It has as yet been but little used in this country, but the reports so far are said to be most favourable. We owe a debt of gratitude to Dr. Dujardin-Beaumetz for giving us this new remedy.

RUSSIAN DIURETICS.

The Russians have great faith in diuretics, and therefore many drugs of this class are popular as household remedies. Some of these, such as foxglove, were in use amongst the peasants long before they were admitted into the category of even extra-pharmacopœial remedies prescribed by professional men. Dr. S. A. Popoff has recently made some researches on the action of certain household diuretics, communicating his results to the recent congress of Russian doctors. Cloud-berries (Rubus chamæmorus) are almost unknown in scientific medicine, though a paper on their diuretic quality was written in 1856 in German by Dr. Trinkovski, who recommended them in hydrocephalus. Dr. Popoff prepared infusions, decoctions, and tinctures, and also an acid which he believes to be the active principle, and found, by experiments on animals, that considerable increase in the urinary secretion was produced by the administration of any of the preparations by the mouth, under the skin, or into the veins. This occurred also when the spinal cord and the splanchnics were divided, and when the animal was under the influence of curare. There was no alteration in the blood-pressure, and but slight palpitation of the heart. The only cases in which any slowing of the heart occurred were those in which a solution of the acid was introduced directly into the jugular. Nikanoroff's experiment of causing defibrinated blood to circulate through the kidney, first alone and then containing the acid in solution, was tried, and the amount of blood flowing out of the renal veins determined, but no positive results were thus obtained. The author has no doubt that the cloud-berry acts by directly stimulating the renal tissue without acting on the heart or circulatory system. It has thus, he says, an effect similar to that of antihydropin (tincture of black-beetles), which is well known in Russia and prescribed frequently, but this latter has the more powerful action of the two.

AFRICANA PARONYCHIA PATINIOSIA.

Dr. Crescencio Garcia, in a note communicated to a Mexican medical journal, mentions the employment of the above-named plant (which grows abundantly in some parts of the country, especially in marshy localities) for the treatment of malarial fevers. He says that he believes that it is almost always beneficial, to some extent even in cases of a pernicious character. When he was a youth he experienced the benefit of it himself during an attack of tertian ague of a choleraic type. The leaves and root are generally made into a decoc-

Digitized by Google

tion, and large quantities drunk by the patient during the pyrexial attack. Dr. Garcia himself prescribes definite acid and alkaline preparations, and though he does not claim for Africana the power of superseding other febrifuges, he finds it very useful as an adjuvant.

BRUCINE.

Brucine seems to be endowed with local analgesic properties of a marked order. The burning sensation imparted to the tongue by certain spices can be relieved, according to M. Mays, by the application of a solution of brucine to the part in the proportion of 5 per cent. It has been employed to assuage the pain occasioned by the presence of ulcers on the tongue and gums. Rubbing the back of the hand with a 2 per cent. solution causes a decided loss of sensibility in the part. The pain resulting from friction with croton-oil is said to be relieved by a 5 per cent. solution; as also that of pruritus vulvæ and the result of a sinapism.

WITHANIA SOMNIFERA.

This solanaceous plant, widespread along the shores of the Mediterranean, is said to possess hypnotic properties. Dr. Trebut has essayed to verify these assertions and isolate the active principle. An alcoholic preparation gave excellent somniferous results in various subjects suffering from emphysema, alcoholism, and phthisis. An alkaloid has been extracted, absurdly called somniferine; its sulphate is crystalline; to it is due the hypnotic effects; it does not dilate the pupil.

DIURETIC PROPERTY OF CUCUMIS CITRULLUS.

Various preparations, chiefly compounded with honey and sugar, are made of the Cucumis citrullus in the south of Russia, where it has great reputation as a diuretic. It has not as yet been used by medical men, but only as a popular remedy. Dr. S. A. Popoff, who has been making experiments with it, found that when the syrup was introduced into an animal's veins, urine poured out of a cannula inserted into the ureter for several minutes.

COCAINE IN VAGINAL OPERATIONS.

Dr. Yakub has successfully employed a 20 per cent. solution of cocaine in two gynæcological operations, kolporrhaphy, or, to it give a less alarming name, suture of the perineum and vagina, and the removal of a papilloma from the posterior wall of the vagina. The solution was applied five or six times, and complete local anæsthesia produced. Both the wounds healed by first intention.

THE LUNACY ACTS AMENDMENT BILL.

THE principal objects of the Lunacy Acts Amendment Bill are:—1. To furnish safeguards against the improper confinement of persons as lunatics. 2. To put a stop to the system of single patients, except in the case of lunatics so found by inquisition, and to prevent the establishment of any new licensed houses. 3. To give facilities for the medical treatment of persons who desire to submit to treatment and of idiot and imbecile children. 4. To enable public asylums to be provided for the reception of lunatics not paupers. 5. To give increased powers to the Court for administering the property of lunatics. 6. To make certain amendments in detail with a view to the consolidation of the Lunacy Acts.

The Bill adopts in the main the recommendations made by the Report of the Select Committee on Lunacy Law in the year 1878. The following clauses are selected from the Act as being most likely to prove interesting to the medical profession:—

I. The power of an "officiating clergyman" and overseer to confine a pauper patient is taken away. A report upon every private patient is to be sent to the Commissioners in Lunacy within a month after the patient's reception as a lunatic, and a visit is to be made to the patient as soon as possible. At the end of three years after the reception of a patient, and at the end of every subsequent year, a special report is to be made on his case. If no report is made, the order for his detention comes to an end. If the report is not satisfactory, the patient is to be visited, and, if it is thought proper, discharged.

II. Any person may apply to the Commissioners for authority to have a patient medically examined with a view to his discharge if his detention should prove improper. Encouragement is given to the relatives of a pauper lunatic to take charge of the lunatic by allowing the visitors of the asylum to pay for the lunatic's maintenance whilst under the care of his relatives. Power is given to the Commissioners to make inquiries as to persons who are treated as lunatics in charitable and religious establishments and in the houses of persons who derive no profit from the charge.

III. Persons who, though not of unsound mind, are desirous of submitting to medical treatment may be received as boarders in hospitals and licensed houses.

IV. Persons not paupers may be received in county and borough asylums upon special terms, and the justices of counties and boroughs are authorised to provide accommodation for lunatics not being paupers, either by enlarging existing asylums or by establishing new asylums. Justices are also empowered to purchase licensed houses.

V. Power is given to the Court to appoint a committee of the estate only of a person who, upon inquisition, is found capable of managing himself, but incapable of managing his affairs. Although under the existing law a person may be deprived of his personal liberty upon an order signed by a relative and two medical certificates, there is no power (except in cases under £2000 or £100 a year) to protect and administer his property without the expensive procedure of an inquisition. This is amended by giving power to the judge in lunacy to exercise all the powers over the property of a person confined under order and certificates, or incapacitated by age or infirmity, which he could exercise upon inquisition.

VI. Miscellaneous amendments: (*a*) As to the letters of patients; (*b*) amendments as to licensed houses; (*c*) amendments as to asylums: (*d*) The provisions for the registration of hospitals where lunatics are received; (*e*) power to retake lunatics escaping into Ireland, Scotland, or England. Power has also been taken to amalgamate the lunacy departments if it is found expedient to do so.

1. (1) This Act may be cited as the Lunacy Acts Amendment Act, 1886, and shall come into operation on the 1st of January, 1887. This Act shall not extend to Scotland or Ireland.

2. (1) The justices of every county and borough shall appoint out of their own body as many fit and proper persons as they shall deem necessary to exercise the powers conferred by this Act upon justices of the peace in relation to orders for the reception of lunatics not being paupers.

3. (1) Except in cases of urgency, no person, not being a pauper or a criminal lunatic, and not being a lunatic so found by inquisition shall be received or detained as a lunatic in any asylum, hospital, or licensed house, or as a single patient, without an order under the hand of a judge of county courts, stipendiary magistrate, or justice of the peace having jurisdiction in the place where the lunatic is. No relative of the person applying for an order under this section, or of the lunatic, or of the husband or wife of the lunatic within any of the degrees of kindred included in the term "relative," as defined by this Act, shall be capable of making such order. (2) The order shall be obtained upon a private application by petition, accompanied by a statement of particulars and by two medical certificates on separate sheets of paper, under the hands of two duly qualified medical practitioners. (5) The petitioner shall undertake that he or someone specially appointed by him will visit the patient once in every six months. (7) One of the medical certificates accompanying the petition shall, wherever practicable, be under the hand of the usual medical attendant, if any, of the alleged lunatic. Where the person to whom the petition relates has been received under care and treatment under an urgency order, neither of the medical certificates accompanying the petition shall be signed by the medical practitioner who signed the certificate accompanying the urgency order. (8) Nothing herein contained shall prevent a consultation between the persons signing the certificates at any time or place before the signature thereof. (9) Upon the presentation of the petition, the judge, if satisfied with the evidence of lunacy appearing by the medical certificates, may forthwith make an order thereon, or may appoint a time, not being more than seven days after the presentation of the petition, for the consideration thereof, of which appointment notice (unless personally given to the petitioner) shall be sent to the petitioner by post. (11) The petition shall be considered in private, and no one, except the petitioner and the persons signing the medical certificates shall, without leave of the judge, be present at

Digitized by Google

the consideration thereof. (12) The judge, if not satisfied with the evidence of lunacy appearing by the medical certificates, may make such further inquiries as he may think fit, and may take evidence on oath, and may visit the alleged lunatic. (13) The judge may make an order on the petition or dismiss or adjourn the same for any period not exceeding fourteen days. (14) Every judge, and all persons admitted to be present at the consideration of any petition, shall be bound to keep secret all matters and documents which may come to his or their knowledge, except when required to divulge the same by lawful authority. (18) No order under this section shall authorise the taking or reception of a patient after the expiration of seven clear days from its date. (19) A copy of the petition shall be sent to the Commissioners or Clerk of the Visitors by the clerk of the asylum, superintendent of licensed house, or person having charge of a single patient, upon the admission of a private patient.

4. (1) In cases of urgency an alleged lunatic (not a pauper) may be received and detained upon an urgency order, accompanied by one medical certificate. (2) The medical practitioner must in such a case have examined the alleged lunatic not more than three clear days previously to the reception of such person. (3) An urgency order may be signed before or after the medical certificate. (4) An urgency order shall, if possible, be signed by a relative or by the husband or wife of the alleged lunatic. (6) An urgency order may be made as well after as before the petition has been presented. (7) Shall remain in force for seven days from its date.

6. No medical certificate accompanying a petition for an order for the reception of a private patient, or accompanying an urgency order, shall be signed by the petitioner or person signing the urgency order, or by certain relatives, or by the assistant of such person.

18. Gives power to justices to order payment of remuneration to medical practitioner for examination of alleged lunatic, whether pauper or not.

38. All letters from patients to be forwarded to the Lord Chancellor or Commissioners unopened.

39. There shall be posted up in every asylum—(*a*) The right of every patient to have any letter written by him forwarded to the Commissioners or Masters in Lunacy. (*b*) The right of every private patient to request a personal and private interview with a Visiting Commissioner or Visitor.

51. The committee of management of any hospital may grant to any officer or servant incapacitated by illness or age, who has served not less than fifteen years and is not less than fifty years old, a superannuation allowance, not exceeding two-thirds of his or her salary.

COURSE OF INSTRUCTION AT HASLAR.

THE sixteen gentlemen who recently obtained commissions as surgeons in the Royal Navy having joined Haslar Hospital, the eleventh session of the Naval Medical School was opened on the 1st inst. Among those present were the Commander-in-Chief, Sir George O. Willes, K.C.B.; Sir John Watt Reid, M.D., K.C.B., Director-General of the Medical Department of the Navy; Inspector-General Dick, R.N.; Captain Colomb, R.N., H.M.S. *Duke of Wellington;* Deputy Inspector-General Mortimer, R.N.; Brigade Surgeon Codrington, A.M.S.; Mr. Giffard, R.N., Secretary to the Commander-in-Chief; Fleet Surgeon Maclean, R.N.; and Flag-Lieutenant Floyd, R.N.

Fleet Surgeon Walter Reid, M.D., who conducts the course of instruction, delivered the opening address. He pointed out the advantages to those entering the Naval Medical Service of a residence at Haslar Hospital, with its many naval associations and surroundings, and gave an outline of the course that would be carried out during the session.

At the conclusion of the address the Medical Director-General thanked the Commander-in-Chief for being present; and Sir George Willes, speaking in response, welcomed into the naval service the gentlemen who had just entered, and offered them some friendly advice, of which, after fifty years' experience of naval life, he knew the great value.

The opening ceremony over, all present adjourned to the mess-room, where the visitors were entertained at luncheon by the officers of the establishment.

THE MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

AT a meeting held on Feb. 26th, the Central Committee of the Association of Members of the College of Surgeons passed the following resolution: "That the Association of Members of the Royal College of Surgeons, believing that the proposal to increase largely the number of Honorary Fellows of the College would in no way tend to a solution of the questions now pending between the Council and the Members, determines to resist the adoption of such a scheme as being detrimental to the best interests of the College, its Members and Fellows."

At the same meeting a sub-committee was appointed to consider and report to the Central Committee such alterations in the existing charters of the College as it may seem advisable to draft, in view of the presentation to the Privy Council of the petition now in course of signature by the Members of the College.

LONDON SANITARY PROTECTION ASSOCIATION.

AT the fifth annual general meeting of this Association, held last Saturday, in their offices, 1, Adam-street, Adelphi, Mr. Robins, F.R.I.B.A., read the report of the Council, which congratulated the members on their numbers, now exceeding 1000. The report gives a long list of country mansions inspected by the engineers during the year, also a list of important buildings in London and the neighbourhood, including amongst others the London Lock Hospital, St. Thomas's Hospital (part of), Grove Hall Asylum, Bow, and Bethnal House Asylum. The general character of the houses inspected was as insanitary as ever, only 5 per cent. being found in perfect order, and 9½ per cent. (in addition) in fairly good order, whilst in 60 per cent. foul air was escaping directly into the houses, and in 21 per cent. sewage was partly retained underground by leakage or choking of pipes.

In moving the adoption of the report, the Chairman said that their system was one of practical testing. The engineers continued to use the "smoke rockets," and found them very useful.

Mr. Timothy Holmes, honorary treasurer, having read his report—showing the receipts (including balance brought forward) to be £2422, and expenditure £1949, leaving a balance of £473, against which are outstanding claims to the amount of about £200—congratulated the Association on the progress which had been made, which he had no doubt would have been much more rapid but for the very satisfactory state of the public health. He alluded in feeling terms to the death of the founder of the Association, Professor Fleeming Jenkin, who had been his own personal friend.

Mr. C. S. Loch, of the Charity Organisation Society, in seconding the adoption of the report, said it was hopeless for them to try to persuade the labouring classes of the importance of keeping their houses in a good sanitary state unless a good example were shown by the class above them.

The report was adopted unanimously, after which all the outgoing members of Council were unanimously re-elected, and the meeting separated after the customary votes of thanks.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5925 births and 4217 deaths were registered during the week ending February 27th. The annual death-rate in these towns, which had steadily increased in the preceding four weeks from 22·1 to 24·4 per 1000, was last week 24·2. During the first eight weeks of the current quarter the death-rate in these towns averaged 23·1, and was 1·6 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 13·1 in Derby, 17·9 in Leicester, 18·1 in Bradford, and 19·3 in Halifax. The rates in the other towns ranged upwards to 28·9 in Manchester, 29·4 in Preston, 30·0 in Plymouth, and 30·5 in Blackburn. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased in the previous four weeks from 360 to 425, declined again

Digitized by Google

last week to 385; they included 161 from whooping-cough, 91 from measles, 34 from scarlet fever, 33 from "fever" (principally enteric), 33 from diphtheria, 32 from diarrhœa, and not one from small-pox. These zymotic diseases caused no deaths last week in Norwich, Derby, or Birkenhead; whereas they caused the highest death-rates in Nottingham, Plymouth, and Blackburn. Whooping-cough caused the greatest mortality in London, Portsmouth, and Salford; measles in Oldham, Nottingham, Plymouth, and Blackburn: scarlet fever in Leeds: and "fever" in Preston and Wolverhampton. The 33 deaths from diphtheria in the twenty-eight towns included 20 in London, 5 in Bristol, and 2 in Birmingham. Small-pox caused 1 death in Liverpool, and not one in any of the twenty-seven other large towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had declined in the preceding fifteen weeks from 90 to 10, rose to 15 on Saturday last, and 7 new cases were admitted to these hospitals during the week, against but 1 and 2 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 479, 584, and 639 in the preceding three weeks, further rose last week to 647, and exceeded the corrected weekly average by 181. The causes of 108, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Leicester, Portsmouth, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Salford, Oldham, Hull, and Norwich.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 24·5 and 22·3 per 1000 in the preceding two weeks, rose again to 23·5 in the week ending February 27th, but was 0·7 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 14·1 and 15·3 in Leith and Aberdeen, to 20·8 in Paisley and 31·0 in Glasgow. The 580 deaths in the eight towns showed an increase of 29 upon the number in the previous week, and included 19 which were referred to whooping-cough, 12 to diarrhœa, 6 to "fever" (typhus, enteric, or simple), 6 to scarlet fever, 5 to measles, 3 to diphtheria, and not one to small-pox; in all, 51 deaths resulted from these principal zymotic diseases, against 53 and 46 in the preceding two weeks. These 51 deaths were equal to an annual rate of 2·1 per 1000, which was 0·1 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 17 and 13 in the previous two weeks, rose last week to 19, of which no fewer than 17 occurred in Glasgow. The 6 deaths referred to "fever" showed an increase of 4 upon the exceptionally low number in the previous week, and included 2 in Greenock and 2 in Leith. Five of the 6 deaths from scarlet fever occurred in Glasgow. The 5 fatal cases of measles included 3 in Edinburgh, and 2 in Glasgow; and the 3 of diphtheria corresponded with the number in the previous week. The 12 deaths attributed to diarrhœa showed a decline from the numbers in recent weeks, but slightly exceeded the number in the corresponding week of last year. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 135, 144, and 153 in the preceding three weeks, further rose last week to 159, and exceeded by 34 the number returned in the corresponding week of last year. The causes of 65, or more than 11 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 33·6 and 31·8 per 1000 in the preceding two weeks, further declined to 30·4 in the week ending Feb. 27th. During the first eight weeks of the current quarter the death-rate in the city averaged no less than 32·3 per 1000; the mean rate during the same period did not exceed 23·5 in London, and 18·5 in Edinburgh. The 206 deaths in Dublin last week showed a further decline from the still higher numbers in the previous two weeks, and included 22 which were referred to the principal zymotic diseases, against 26 and 20 in the previous two weeks; 18 resulted from whooping-cough, 2 from "fever," 1 from diphtheria, 1 from diarrhœa, and not one either from small-pox, measles, or scarlet fever. These 22 deaths were equal to an annual rate of 3·3 per 1000; the rate from the same diseases last week did not exceed 2·7 in London and 1·4 in Edinburgh. The fatal cases of whooping-cough, which had been 10 and 16 in the previous two weeks, further rose last week to 18, and exceeded the number returned in any week since the second of this year, when they were 19. The 2 deaths referred to "fever" corresponded with the number in the previous week. Four inquest cases and 3 deaths from violence were registered, and 57, or more than a quarter, of the deaths were recorded in public institutions. The deaths both of infants and of elderly persons showed a considerable increase upon the numbers in the previous week. The causes of 30, or nearly 15 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

INDIA OFFICE.—The Queen has approved of the following admissions to Her Majesty's Indian Medical Service:—Henry Robert Woolbert, George Henry Baker, Thomas Grainger, M.D., Joseph Rosamond Adie, Arthur Charles Younan, Alfred William Alcock, Arthur Rea Edwards, and John Macfarlane Cadell to be Surgeons in the Bengal Medical Establishment.

The Queen has approved of the retirement from the service of the following officer of Her Majesty's Indian Military Forces:—Surgeon-Major Richard Power, of the Bengal Army. The following officers are granted a step of honorary rank on retirement:—Surgeon-Major Edwin Clement Bensley and Surgeon-Major Richard Power, both of the Bengal Army, to be Brigade Surgeons.

RIFLE VOLUNTEERS.—18th Lancashire (Liverpool Irish): David Edgar Flinn, Gent., to be Acting Surgeon.

Correspondence.

"Audi alteram partem."

THE RATIONAL (?) METHOD OF TREATMENT OF HYDROPHOBIA.

To the Editor of THE LANCET.

SIR,—I think it very necessary to give a caution in regard to Dr. Roy's recommendation of the hypodermic injection of snake-poison in rabies. Dr. Roy tells us "that while brooding over our failures it struck him that Nature could not be so improvident and callous as to leave us thoroughly helpless and unprotected"; and so the brilliant idea is advanced that Nature has been good enough to provide against the ills of mad dog bite by sending us blessings in the shape of venomous snakes. Dr. Roy may be unaware that curara has certain, so to speak, physiological properties in common with cobra-venom; and he is possibly unaware also that curara has been recommended as a remedy in hydrophobia—not, it must be confessed, with any very great success. Passing over the crude, and in some particulars incorrect, description of the physiological action of snake-venoms, I come to the extraordinary recommendation that one grain of cobra-venom should be injected every two hours into the tissues of a person suffering from rabies, according to the symptoms observed. In determining the dose of venom to be injected, Dr. Roy states that he has fixed upon the "happy medium," as ten or fifteen grains are injected into the tissues by a good bite. Now, it is impossible for us to determine what quantity is injected into the tissues at one bite; all we know is that about thirteen grains of the liquid venom—which upon drying is reduced to four or five grains—are obtained from a full-grown vigorous cobra by a certain process, and that that quantity represents almost, if not quite, the contents of the poison glands at one time.

The question then arises, What quantity of cobra-venom would be sufficient to destroy the life of a full-grown man? As we have no direct evidence to guide us, we must take such cases as bear upon the subject. There is a case on record (Chevers's Medical Jurisprudence) in which one krait —a snake having poison glands of a much smaller capacity

Digitized by Google

than those of the cobra—killed three men and seriously poisoned a fourth, one after the other. Supposing the glands to have contained eight grains of the liquid venom—an excessive estimate, seeing that the animal was only three-quarters grown—the last man mortally bitten could not have received more than two grains at the very utmost, sufficient to prove fatal in less than eighteen hours. The Indian Snake-poison Commission, of which I was a member, showed that a dog weighing 17 lb. could be killed by the hypodermic injection of one-sixteenth of a grain of dried cobra-venom, equal to about one-third of the fluid venom, in thirty-two hours. It is therefore highly probable that the smallest fatal dose of liquid cobra-venom does not exceed two grains, and that is giving the very outside limit.

Now for the next point. Everyone practically acquainted with the subject knows that cobra-venom is a cumulative poison. After the injection of a grain into the tissues of a full-grown man no symptoms would be manifest in two hours, so two grains would certainly be injected—an undoubtedly mortal dose.

Would it not have been better for Dr. Roy to have put his theory to the test first in the case of the lower animals. Mad dogs are by no means uncommon in India, and, fortunately, we are not tied down by any foolish restrictions. At any rate, such an experiment as he recommends in the case of the human subject would be utterly unjustifiable in the face of the facts set forth, and in the absence of any successful experimental investigations on the lower animals.

I am, Sir, yours truly,

Goalundo, Bengal, Jan. 29th, 1886. VINCENT RICHARDS.

LUNACY IN THE DOMESTIC CIRCLE.

To the Editor of THE LANCET.

SIR,—The Lunacy Laws, which are about to be consolidated and amended by Acts of Parliament, introduced by the Lord Chancellor, who is the State guardian of lunatics, as he is of minors, recognise, as heretofore, but two conditions of mind. These are lunacy and sanity. The intermediate state, of which medical practitioners are fully cognisant, displays itself in the form of eccentricities, often innocent, but sometimes malign, and is not recognised by law till the subject is so lost to self-control as to be unable to resist breaking the law. Nor is it as a rule admitted, if the crime falls short of something very heinous, that this intermediate state divests an individual of responsibility. The great dramatist so depicted his ideal in "Hamlet" that experts of the present day are divided in opinion as to whether he intended the madness to be feigned or real. A nineteenth century jury would in all probability in such a case realised acquit a murderer on the ground of insanity, while in the absence of murder they would on similar evidence to that of the dramatist pronounce the person sane. There are many "Hamlets" at large in society, causing as much remorse in their family circle as Hamlet is represented to have done, yet equally difficult to pronounce insane. Some of these will not be recognised as insane till they become murderers. Many of the criminal lunatics have passed through the intermediate state recognised by medicine, but not admitted by law. Most people can point to friends or acquaintances a little "touched." The peace and happiness of many a domestic circle are marred by such ones. So long as these remain innocent they may be fairly left to themselves, but something is needed to enable relatives to have control exercised whenever the want of mental balance threatens to lead on to such disregard of moral and social order as is often seen. The line between the individual of one false idea and the lunatic is indefinable. The false impression in the sane should be transient, while in the insane it is persistent. It may not be easy for the law to take cognisance of such a one, "nor stands it safe with us to let his madness range." If, however, a medical man certifies that a person is of unsound mind, he renders himself liable to an action at law, in which a jury may take a different view, and thus the medical man may be subjected to heavy costs and damages. In the proposed amendment of the Lunacy Laws protection should be given to practitioners certifying to the best of their ability and belief, or they will evade the responsibility, and leave lunatics to the care of their friends.

I am, Sir, yours obediently,

March 1st, 1886. GENERAL PRACTITIONER.

"THE CORPUS LUTEUM."

To the Editor of THE LANCET.

SIR,—The leader in your issue of January 30th, on the above subject, raises some old questions of great importance, which are not yet finally settled, though the facts upon which their settlement depends are known; they are as follows:—A corpus luteum is a structure developed in the higher mammalia for the purpose of closing, in a round-about way, the wound of the ovary caused in the process of extrusion of an ovum; the plicated yellow membrane developing ultimately into connective tissue and a cicatrix. The complicated method of this process has probably some additional purpose which is not at present clear. A corpus luteum is a corpus luteum or it is not one—that is to say, there is no such thing as a false one. Again, all corpora lutea are of menstruation, or more correctly, of ovulation, and the great question raised is, in what way does the corpus luteum, when impregnation occurs, differ from the corpus luteum when impregnation does not occur? The answer is that while there is often a difference in size, there is no such constant difference as to lead us to say with certainty that impregnation has or has not occurred. The only certain difference is in their duration: in the one case the duration of the corpus luteum as a body of characteristic appearance, and not simply a shrivelled mass of connective tissue, is limited to five or six weeks; in the other, if pregnancy is maintained to the full time, to a similar period after parturition, or after abortion if that takes place. The average size of the two, I believe, is frequently the same, and not very large, the average longest diameter not exceeding half an inch; the largest corpora lutea, which sometimes, though rarely, almost equal the ovary in size,[1] and measure from three-quarters to an inch in length, are, with some exceptions, only developed when pregnancy occurs; an exceptionally large corpus luteum without pregnancy is figured by Coste in his Atlas (Plate I[a], Fig. 5), and I have seen one in an ovary removed by Mr. Willett for early cystic disease. It is well known that there may be no corpus luteum at all either with or without pregnancy, and it appears that the corpus luteum is subject to the same variations in extra- as in intra-uterine pregnancy. Coste recognised the difficulty, and, on page 260 of the "Histoire du Développement des Corps Organisés," he answers the question of the possibility of being able to determine, by the characters of the corpus luteum, if a woman had or had not been lately pregnant. "Je crois, pour ma part, à la possibilité d'une semblable détermination,.....mais il ne faut pas oublier que, dans une question aussi délicate, on ne peut avoir recours à ce moyen de conviction que pour les cas où il a une incontestable signification, car il y a des circonstances dans lesquelles on ne peut en tirer aucun parti."

The matter appears to stand thus: we are unable to say, with certainty, in a large proportion of cases, from the characters of a corpus luteum whether pregnancy has or has not occurred, and the value of this as a single criterion for our own information is limited, and for medico-legal evidence quite unreliable. No one, however, who has carefully studied the anatomy of parturition and abortion should have much difficulty in deciding whether a uterus and vagina have undergone one of these processes recently, say, within a month or six weeks of the event, especially in such cases when some complication has caused the death of the patient.—I am, Sir, your obedient servant,

Harley-street, Feb. 9th, 1886. WALTER G. A. GRIFFITH.

"MR. HORSLEY'S CRITICISM OF PROFESSOR SCHIFF."

To the Editor of THE LANCET.

SIR,—Now that Dr. Huggard has made the *amende honorable*, I should be loth to seek a further hearing did I not feel that the importance of Professor Schiff's latest announcement deserves special attention by your readers. Dr. Huggard quotes Professor Schiff (*verbatim*) as saying that although the opinion that the crossed lateral (pyramidal) tract is motor is a very general one, he (Professor Schiff) is going to prove that it has no such function. It

[1] See specimen No. 3072, Path. Series, St. Bartholomew's Hospital Museum.

Digitized by Google

certainly is a very general opinion, and it seems to me that Professor Schiff will have to follow the example of Professor Ptthmllnsprts, in Kingsley's "Water Babies"—i.e., "get up very early in the morning and eat his breakfast overnight" "in order to prove" the contrary; and yet I daresay, like that distinguished person, he too will do it, "at least to his own satisfaction."—Yours sincerely,

Park-street, W., Feb. 26th, 1886. VICTOR HORSLEY.

P.S.—The last paragraph of Dr. Huggard's letter will be fully criticised in my paper in the forthcoming April number of *Brain*.

LIVERPOOL.

(*From our own Correspondent.*)

A YEAR'S PORT SANITARY WORK.

DR. J. STOPFORD TAYLOR, the medical officer of health, has just presented to the Health Committee his annual report on the work done by the officers of the port sanitary authority, 1885. Of a total of 20,894 vessels which entered the port during the year, 4078 were inspected, of which 2841 were British, 3873 were found in fair sanitary condition, and 205 defective. In 72 the forecastles, peaks, deck-houses, or cabins required cleaning, as well as painting or lime-washing; in 12 the bulkheads were defective; in 80 there was deficient ventilation; in 22 the closets were faulty; and in 19 the deck over the quarters occupied by the crew required caulking. The improvements mentioned in former reports continued, and all suggestions of the inspector were readily complied with. The condition of the French, Spanish, Italian, Russian, and Greek vessels had been fairly satisfactory during the year; the German, Danish, Belgian, Dutch, Swedish, and Norwegian continued to be kept in excellent order. The Liverpool-owned vessels were, as a rule, in very good condition, and so also were most of the English ships. The steamers carrying Lascar crews appeared to a casual observer to be crowded and untidy, but on inspection there was sufficient room, and the crews' quarters were in a very fair condition. The Spanish ships had shown a decrease, which might, in a measure, be accounted for by the epidemic prevalence of cholera in Spain.

THE LATE REV. HUGH STOWELL BROWN.

Liverpool has sustained a severe loss in the death of the well-known Baptist minister, the Rev. Hugh Stowell Brown. The deceased was a warm supporter of the local medical charities, whose claims he used to advocate long before the institution of Hospital Sunday, in the establishment of which he took a warm interest, and was from the first a member of its committee.

THE DISPENSARIES.

The annual meeting of the Liverpool Dispensaries was held last week. A resolution to abolish the honorary medical appointments, substituting a paid chief medical officer at each of the three dispensaries, was carried by a small majority. A great change has taken place in the position of these institutions within the last thirty years. Formerly the honorary appointments were eagerly sought and keenly competed for by local physicians and surgeons, who subsequently rose to the highest position. But of late years this has not been so, and there has been comparatively little competition for the honorary offices, although a pecuniary honorarium has been added of forty guineas annually. There is much to be said in favour of the proposed change. It is to be hoped that better accommodation will be provided for the resident medical officers, both present and future, at the North Dispensary, which was built a great many years ago, in which the apartments, especially the bedrooms (if, indeed, they deserve such a name), are simply wretched. It speaks volumes for the patience of the resident medical officers that they have so long endured such a state of things.

THE LORD BISHOP AT THE ROYAL INFIRMARY.

The Right Rev. Dr. Ryle, Bishop of Liverpool, preached on Sunday last in the chapel of the infirmary at the afternoon service. The chapel, which is the gift of a former president, was filled to overflowing by the patients and officials. The musical part of the service was well rendered by a choir of nurses. After the service the bishop visited the wards.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

NEWCASTLE INFIRMARY.

IT was stated at the annual meeting of this institution and some points of which I briefly alluded to in my last letter, that the idea generally prevails that all in-patients are admitted in consequence of being provided with a letter from a governor who is a subscriber to the hospital of two guineas a year, and that these letters are sometimes thoughtlessly given to impostors who, on the strength of them, are without question received into the hospital. This is not the case; no patients are admitted whose cases are not real and generally pressing ones; and, further, it is shown that many are received who have no letter. It is shown in the report that of the 2846 admitted in the past year, only 1294, or less than one-half, were provided with letters. Cases of accident are always received the moment they reach the door. It was also pointed out, as regards the fact of the number of casuals relieved being double that of five years ago, that one cause has had a powerful effect on the increase of late—namely, the large amount of distress which has prevailed in the district. "Hunger and nakedness have produced disease, whilst the sufferers, often clerks and artisans who have once held a respectable position in society, having been long without employment, have not the means of procuring food, much less of applying to their ordinary medical advisers for relief." It was also shown in the report that the financial position of the infirmary is far from being satisfactory, as evidenced by the fact that the annual subscriptions have remained nearly stationary in amount for nearly a quarter of a century, and for the past year have been actually less by about £150 than they were ten years ago. Altogether there was a deficiency of income of over £5000. The infirmary had received from the Hospital Sunday Fund £1916 14*s.* 7*d.*—more than last year by £169 3*s.* 5*d.*

THE MATCH-POISONING MANIA.

The match-poisoning mania appears to be extending in the North. A case is reported from Sunderland in which a young man, aged twenty-two, during some depression of mind from ill-health, attempted to destroy his life. He steeped the heads of a box of matches in some hot tea, which he swallowed. Fortunately the rash act was observed by his father, and immediate steps were taken to counteract the poison, so far apparently with success.

DEATH FROM LEAD POISONING.

An inquest has been held by the city coroner of Newcastle on the body of Eliza Jane Hutchinson, who had died rather suddenly. It was shown that the deceased, a single woman aged twenty-eight, had worked for three years at a white lead factory in Newcastle, and had been under treatment three months ago at the Newcastle Infirmary for lead poisoning. In her last and fatal illness she was seized with sickness, pain in the head and limbs, and then appeared to go into a fit of an epileptic nature, from which she did not recover. The verdict was "Death from natural causes accelerated by the effects of white lead poisoning." It is to be feared that these cases will recur from time to time, unless some means can be devised for doing without female hands in the manufacture of white lead.

NEWCASTLE CLINICAL SOCIETY.

The annual banquet of the Clinical Society took place on the 19th ult. at the Central Station Hotel in this city. Dr. Limont presided, and in addition to being well attended by practitioners in the district, the entertainment was very spirited and successful. Dr. Campbell undertook the onerous and important post of secretary, and he and the other promoters are to be congratulated on the result.

DEATH OF DR. MORRIS, CHESTER-LE-STREET.

Great regret has been felt here in medical circles by the almost sudden death of Dr. Walter Cameron Morris, an active general practitioner at Chester-le-Street. Dr. Morris received a severe chill in the course of his arduous duties, which brought on acute enteritis, from which he never rallied, dying on Feb. 12th, after five days' illness. He was attended by Dr. Drummond of this city, and also by Dr. Wards of Pelton Fell. Dr. Morris held several important public appointments, as well as being ordinary medical

Digitized by Google

attendant to the Earl of Durham and the household at Lambton Castle. He was in his thirty-sixth year, and leaves a widow and two children.

Newcastle-on-Tyne, February 22nd.

EDINBURGH.

(*From our own Correspondent.*)

THE LATE DR. SIDEY.

By the death of Dr. James A. Sidey Edinburgh has lost one of its best-known practitioners, and a citizen of wide culture and marked literary tastes. In addition to his very extensive general practice, Dr. Sidey held the post of Surgeon to the Calton Prison, one of the most extensive penal institutions in Scotland, and one which has of late years undergone great improvement in its sanitary and domestic arrangements under his advice. Striking evidence of the wide respect in which the deceased gentleman was held was forthcoming last Monday on the occasion of his funeral, which was attended by a very large gathering of his professional brethren and of the general public, notwithstanding the extremely inclement weather which prevailed.

SMALL-POX AT QUEENSFERRY.

Some anxiety has been felt in the neighbourhood of Edinburgh during the last few weeks in consequence of an outbreak of small-pox which has occurred in and around Queensferry, a small town about eight miles from this city. The occurrence was the more alarming from the fact that nearly 2000 operatives are employed there in the construction of the Forth railway bridge, a gigantic piece of engineering work, which it will take several years to accomplish. It was feared that the disease might spread rapidly amongst these workmen, and Queensferry become a focus whence its ravages might spread in various directions. By the prompt action of the local sanitary authorities, and especially of Dr. James Hunter, the medical officer in charge of the works, this risk has been obviated; for at an expense of about £500 a floating hospital has been fitted up on board the *Hugomont*, which provides for the complete and early isolation of cases as they arise. The ship has been arranged on the general plan adopted in the floating hospital on the Thames, and is moored in the Firth of Forth at a safe distance from the shore. Arrangements for thorough fumigation and disinfection have also been completed, and it is anticipated that the disease will shortly be entirely stamped out.

ROYAL SOCIETY OF EDINBURGH.

At the last meeting of this Society, Professor Douglas Maclagan, Vice-president, in the chair, several important papers were read relating to physical science. Sir William Thomson dealt with an interesting point in regard to Newton's law of attraction; he finds that in the case of particles of matter at distances of less than ten micro-millimetres from one another the general law that attraction varies inversely as the square of the distance does not hold true, but that a mutual attraction in an enormously increased ratio comes into action. As an explanation of this deviation from the Newtonian law he offers the ingenious suggestion that there are mutual movements established amongst the molecules of the contiguous particles of matter, in virtue of their close contiguity, analogous to those which result in the cohesion of the molecules, of which each of the particles of matter is itself made up; and that this, superadded to the ordinary gravitation of masses of matter, explains the sudden increase in mutual attraction observed when dealing with these minute distances. A paper by Dr. John Aitken on the effect upon climate of the small conducting power of snow was communicated by Professor Tait. Dr. Aitken finds that although the temperature observed on the surface of snow may be several degrees below zero, that registered immediately underneath the snow layer is not below 32°F. This accounts for the fact that advanced vegetation may be found to have taken place under a thick layer of snow; but although the vitality of vegetable organisms is thus preserved by the presence of a layer of snow which prevents radiation of heat from the soil beneath it, such a soil is cut off from the absorption of heat from the sun's rays so long as the covering of snow persists, and as a result there is great retardation of the season in regions where a great thickness of snow must be removed before the sun's rays gain access to the surface of the soil.

Edinburgh, March 2nd.

ABERDEEN.

(*From our own Correspondent.*)

DEAN OF THE MEDICAL FACULTY.

PROFESSOR STEPHENSON has been appointed Dean of the Medical Faculty in room of Professor Brazier, who lately resigned both that office and the secretaryship, which has not yet been filled up. Many graduates and students will have pleasant recollections of Professor Brazier as the kind and genial secretary who was ever willing to give them the benefit of his advice and lend a sympathetic ear to their complaints.

THE PHYSIOLOGY CHAIR.

Mr. J. McGregor Robertson, M.A., M.B., C.M., Muirhead Demonstrator of Physiology in Glasgow University, is a candidate for the Chair of Physiology in Aberdeen University. He graduated with honours in Medicine and Surgery in 1880, and has since then devoted himself to physiology. He has also written a text-book on "Physiological Physics."

MEDICAL OFFICER OF HEALTH FOR THE CITY.

Dr. Matthew Hay, Professor of Medical Jurisprudence in the University, and Dr. Theodore Thomson, Resident Assistant Medical Officer to the South-Eastern Hospital, London, are candidates for the post of medical officer of health for Aberdeen. Dr. Hay's professorial duties occupy him only one hour a day for three months in the year, so that practically he could devote the whole of his time to the work of the sanitary department. In his letter of application, Dr. Thomson says he acquired his special public health training under Dr. Littlejohn of Edinburgh, and during the last two years he has made a special study of the various forms of acute infectious diseases, with their prevention, and the kindred subjects of isolation and disinfection.

ABERDEEN ROYAL INFIRMARY.

In their report to be submitted to the next general meeting of the managers of the Royal Infirmary, the Special Sub-inquiry Committee recommend that the medical staff should be increased by (1) a medical officer for diseases of women, (2) two assistant physicians, (3) a surgeon for diseases of the ear, (4) a medical officer for diseases of the skin, (5) a second assistant surgeon, and (6) two additional house residents, a surgeon, and a physician. The Committee of Management must be sadly perplexed by the number of plans for the reconstruction of the hospital submitted for their consideration. Mr. Saxon Snell has sent in a third sketch plan which shows an extension of the medical side of the present building, a new surgical pavilion, and the adaptation of the surgical side of the present building for clinical and administrative purposes. This scheme provides 236 beds, at an estimated cost of £25,000. The financial problem is not the least of the difficulties in the question of remodelling the hospital, and it must be disheartening to the managers, and more particularly to those specially interested in and working out the proposed changes, to find the income for the past year fall short of the expenditure by no less a sum than £956.

SMALL-POX AT WOODSIDE.

Small-pox has made its appearance among the rag-workers at Woodside, near Aberdeen; but the cases were at once removed to the local epidemic hospital, and so the disease is not likely to spread. Almost every year rags give rise to one or two cases of small-pox among the workers in the rag department of the Woodside Paper Works, but prompt isolation has hitherto prevented an epidemic.

OPERATION FOR CANCER OF THE STOMACH.

At a recent meeting of one of the Medical Societies Professor Ogston gave a short account of an operation which he had performed on a patient suffering from cancer of the stomach. Excision of the pylorus, the seat of the disease, was meditated, but the cancerous affection was so extensive that this was neither advisable nor possible, and Dr. Ogston therefore determined to make a duodenal fistula. A loop of

Digitized by Google

the duodenum was included in the wound in the abdominal wall, and an opening was made into the bowel on the second day. The patient made an uninterrupted recovery; was regularly fed through the opening in the duodenum after the second day; was out of bed in ten days after the operation, and in three weeks left for his home in the country.

Aberdeen, March 2nd.

IRELAND.

(From our own Correspondent.)

DUBLIN HOSPITALS COMMISSION.

THE sittings of the Dublin Hospitals Commission were resumed last Monday, when some of the medical staff of Mercer's Hospital were examined, to reply to the charges made against that institution by Mr. O'Grady, the senior surgeon. Mr. Holmes, Treasury Remembrancer, a member of the Commission, elicited the fact that there were several gentlemen on the Board of Governors who did not contribute a single shilling to the funds of the hospital, which he considered one of the most important circumstances brought out in the inquiry. The inquiry was continued on the following day. The report of the Commission, which has been so long delayed, will be waited with interest.

THE COLLEGES AND THE LORD-LIEUTENANT.

The following address has been presented to His Excellency the Lord-Lieutenant by the President and Fellows:—"We, the President and Fellows of the King and Queen's College of Physicians in Ireland, beg to approach your Excellency on your arrival in this country as Her Majesty's Viceroy. Our College, which derives its existence from charters granted by Her Majesty's royal predecessors, King Charles II. and King William III. and Queen Mary, and which had additional powers conferred upon it by Her Gracious Majesty in 1878, has ever been mindful of the important trust committed to it, and has endeavoured to discharge its functions by furthering the advancement of medical science and by securing a succession of educated physicians for the service of the State. The King and Queen's College of Physicians has at various times rendered its aid and professional advice to the Government in devising and carrying into effect measures dealing with the public health, and now, as at all times, the College will consider it to be its duty, as it is its anxious desire, to afford every assistance to Her Majesty's Government in all matters relating to both curative and preventive medicine." An address has also been presented by the Royal College of Surgeons to the Lord-Lieutenant, welcoming him to the country as the representative of Her Majesty, inviting his favour to the corporation, and expressing the hope that in future years his recollections of Ireland may be of a pleasurable kind.

BELFAST MAIN DRAINAGE.

This scheme will shortly come before a select committee of the House of Commons, and it is generally expected that it will be opposed by a section of the ratepayers. There is no doubt, however, that a drainage scheme of some kind is urgently required, for it is stated that at present the sewers are blocked up by the tide twice every day, while sewer gas is forced up and into dwelling-houses by defective traps. The chief objection against the scheme of the borough surveyor is that the sewage will go back on the slob and cause a nuisance; and Mr. Lanyon, an eminent engineering authority, believes that this result will take place because the discharge of sewage can only take place after half-ebb, and that it will have to force its way out against the higher level of low water. It is, however, asserted that the discharge can take place and be completed during the first half of the ebb, which removes the difficulty suggested. On the whole, the scheme of the Corporation appears a feasible one, and one which it is to be hoped will not be delayed by a futile opposition.

POLLUTION OF THE RIVER LEE.

Last week in the Vice-Chancellor's court application was made to make a consent a rule of court at the relation of the Cork Corporation against the Macroom guardians. The action was instituted for an injunction to restrain the defendants from using any sewer, &c., for conveying sewage into the Sullane, thereby affecting the purity of the water of the river Lee and rendering the same unfit for use and dangerous to the inhabitants of Cork. It appears that the water-supply of Cork is obtained from the Lee, about two miles above the city, and that the towns of Macroom and Massytown are on the banks of the Sullane, one of the tributaries of the Lee. Some time since several cases of typhoid fever occurred in Cork, which were suspected to be due to impure water-supply, and on inquiry it was found that the drainage of Macroom and the other town was conveyed into the Sullane, and the proceedings above referred to were taken to remedy the evil. The Macroom guardians have agreed to carry out a plan by which any further pollution of the water will be prevented.

NATIONAL LYING-IN HOSPITAL.

In addition to the two large maternity institutions, which have performed so much valuable work in Dublin amongst the poorer classes for so many years, a third lying-in hospital was established some time since, and the first annual meeting of the friends of the hospital was held last week. In consequence of the distance at which it is located from the other lying-in institutions, and because of the large suburban district with which it is contiguous, there is no doubt that it will carry out a very useful work, more especially when the hospital is recognised by the various licensing bodies. The master of the hospital is Dr. William Roe, professor of midwifery in the Royal College of Surgeons, who has had great experience in obstetric practice.

The annual meeting of the Dublin Sanitary Association was held last week, and the incoming president for the ensuing year, Dr. Grimshaw, delivered an address bearing on the sanitary condition of the city.

Dublin, March 2nd.

MEDICAL NOTES IN PARLIAMENT.

The Sale of Poisons.

IN the House of Lords on the 26th ult., in reply to the Earl of Milltown, Earl Spencer stated that the Government were now considering the question of the sale of poisons, and in a very short time he hoped to be able to inform the House whether they intended to introduce a Bill.

The Lunacy Acts Amendment Bill.

The Lord Chancellor, in moving on the 1st inst. the second reading of the Lunacy Acts Amendment Bill, stated that it was impossible to exaggerate the importance of the subject with which this Bill proposed to deal, and few would deny the necessity that existed for fresh legislation with regard to it. The provisions of the Bill, which is substantially the same as the one introduced last year by the Earl of Selborne, having been clearly explained, Lord Coleridge, referring to the proposed extinction by degrees of all private asylums, said that he had been of opinion since he had gained any experience in this matter that it was impossible to effect a real and satisfactory change in the lunacy law as long as it remained possible—human nature being what it was—for those persons who kept asylums to have an interest in retaining patients who were placed in their charge. He thought no one with any experience at all could doubt—regard being had to human nature—that to give a medical man an interest in retaining a patient was to subject his moral nature to a strain which few could bear. He trusted that, so far as this Bill went, something would be done to prevent the multiplication of those asylums. He was glad to see that there were alterations proposed in the Bill regarding the present state of the law as to the examination of patients. He thought that some more stringent provisions might with advantage be introduced in the Bill. Especially was this the case with respect to the examination of the lunatic when it was conducted by the magistrates. It should always be conducted with the assistance of a medical man, and after notice to the lunatic himself that he was to be subject to such an examination, in order that he might be given an opportunity of taking part in the proceedings, and of explaining, if he could do so, the circumstances on which his alleged lunacy was founded. He had known of cases where persons had been examined without the slightest idea on their part that they were being examined, and without the slightest expectation on their part that their imprisonment in an asylum was pending. So far as he could see, another useful provision was not to be found in the Bill: According to the present state of the law, the person who put the law

Digitized by Google

in force against a lunatic, however *bonâ fide* he might act, was not protected. He could not help thinking that this state of the law in many instances caused great hardship, the persons so acting being oftentimes subject to actions for heavy damages. He submitted that some provision protecting the person who acted in a *bonâ fide* manner should be inserted in the measure. The Earl of Milltown, Earl Beauchamp, Lord Bramwell, and others having joined in the debate, the Bill was read a second time.

The Lighting and Ventilation of the House.

On the 2nd inst. the Earl of Limerick moved that the evidence of John Percy, M.D., taken before the Select Committee on the Office of the Clerk of Parliaments and Office of the Gentlemen Usher of the Black Rod in session 1869 be laid upon the table, and that the same be printed. The evidence would be of much value in reference to the lighting and ventilation of the House. The motion was agreed to.

The Pollution of the Thames.

In the House of Commons, on the 25th ult., Mr. Childers, in reply to Mr. T. Rogers, said that the recommendations of the Royal Commission on the Pollution of the Thames by the outfalls at Barking Creek and Crossness had been repeatedly under the consideration of the Metropolitan Board, who have charge of the sewerage of London. They have not yet finally reported their conclusions, but he would press the Board for an early answer.

The Lunacy Commissioners' Reports.

In answer to Mr. W. Corbet, Mr. Childers said that the English Commissioners will undertake to have ready by the end of April, for presentation to Parliament, a tabular statement showing the total number of lunatics in various institutions up to the beginning of each year. The Scotch Commissioners expect to be able to present their report in future by the middle of June.

Army Medical Officers.

In reply to Sir T. Lawrence, Mr. Campbell-Bannerman said that no British medical officers had been sent to report on the campaign between Servia and Bulgaria.

Aberdeen University.

On the 2nd inst., in reply to Mr. J. Campbell, who asked the Secretary for Scotland whether he was not mistaken in referring recently to the chair of physiology at Aberdeen as being at present vacant, Mr. Trevelyan stated that he had received a letter from Professor Stirling intimating that he does not propose formally to resign till the close of the present session.

Medical News.

UNIVERSITY OF CAMBRIDGE. — At a congregation held on the 25th ult. the degree of M.B. was conferred on

W. D. Anderson, Trinity.

ST. ANDREWS UNIVERSITY.—The honorary degree of Doctor of Laws has been conferred on

Dr. A. Keiller, F.R.S.E.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 11th ult.:—

Pridham, William F., Cromwell-crescent, South Kensington.

Passed on the 18th ult.:—

Deyns, Charles John, Fenny Stratford, Bucks.

Passed on the 25th ult.:—

Kempe, Charles Edward, Ladbroke-grove-road.
Ward, Stanley Edward, Haverhill, Suffolk.

THE death is announced of Dr. Pleischl, formerly assistant to Professor Oppolzer of Vienna.

ON the 27th ult. Dr. B. W. Richardson delivered a lecture on the "Medical Aspects of the Temperance Question" in the Free Assembly Hall, Edinburgh, in the presence of a large audience.

RATING OF PUBLIC CHARITIES.—A conference of authorities of public charities will be held at Guy's Hospital on the 6th inst. (to-day) at 3 P.M., to consider the best means of promoting the passing of an Act of Parliament to restore to public charities exemption from liability to local rates.

ROYAL INSTITUTION.—Professor Arthur Gamgee, M.D., F.R.S., Fullerian Professor of Physiology, R.I., will on Tuesday next (March 9th) begin a course of six lectures on the Function of Circulation. Dr. John Abercrombie, senior, has been elected a member of the Institution.

ROYAL BERKSHIRE HOSPITAL.—At the forty-seventh annual court of the governors of this institution, held on the 23rd ult., it was reported that the balance of £1933 due to the treasurer at the beginning of 1885 had by legacies and donations been paid off and a small balance left to be carried to the current year. The ordinary receipts amounted to £5710 and the expenditure to £6940. The number of in-patients had amounted to 1038, and out-patients to 1536.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—The annual general court of governors of this institution was held on the 26th ult., when the committee reported that the number of in-patients during the year was 479, as compared with 471 in 1884; and of out-patients, 7132, as compared with 6015. The reliable income of the hospital was about £2000 per annum less than the required expenditure, and they therefore appealed most urgently for new annual subscriptions, which really form the surest portion of income, donations necessarily being of a fluctuating character, and requiring the committee to make extraordinary efforts to meet expenditure. The deficit at present existing was £450, against £420 last year. The expenditure for the past year had been £3562.

HASTINGS HOSPITAL.—An important discussion, reopening the question of the building site of the new hospital, which, after having been before the public for something like thirteen years, was believed to be definitely settled, took place at the meeting of the governors of the institution on the 2nd inst. Notwithstanding the fact that the former edifice has been wholly demolished and the fresh foundations got in, it was proposed that another site be purchased at a cost of £6000 for the purpose of erecting thereon a new hospital. The arguments in favour of the new project were that the ground on which the old infirmary stood could be sold for £15,000, and that the new site would be more open and in every way more suitable. Eventually a vote was taken, when 47 were in favour of the motion and 22 against. The minority demanded a poll.

MEDICO-PSYCHOLOGICAL ASSOCIATION. — The quarterly meeting of this Association was held at Bethlem Hospital on the 24th ult., Dr. H. Rayner in the chair. Dr. Mickle read a paper on "Some Abnormal Forms of Breathing," and a paper by Dr. Savage was also read on the subject of "Drunkenness in relation to Criminal Responsibility," in the discussion upon which latter paper the opposite views held by judges in recent cases were remarked upon as leaving the present legal aspect of the subject in an unsatisfactory state.—The examinations for the certificate in Psychological Medicine will be held as follows: For England, on March 29th and 30th, Nov. 30th, and Dec. 1st, at Bethlem Hospital; for Scotland, in July next (date unfixed), and Dec. 11th, at the Royal Edinburgh Asylum; and for Ireland, on Jan. 22nd, at Dublin. Candidates intending to present themselves for examination must give notice thereof fourteen days prior to the examination. In England, to Dr. Rayner, Hanwell; in Scotland, to Dr. Rutherford, Dumfries; and in Ireland, to Dr. Courtenay, Limerick.

HOSPITAL SATURDAY FUND.—The board of delegates of this fund met on the 27th ult., when it was decided to hold the ladies' street collection on July 17th next, the workshop collection being due and payable, as usual, on and after the first Saturday in September. A statement was submitted by the Secretary, showing that the organisation had, during the twelve years of its existence, distributed £74,271 among the hospitals, dispensaries, convalescent homes, and surgical appliance societies of the metropolis. In 1874, when the fund was started, only £6141 was collected, and six years afterwards there was merely an addition of £11, but in 1885 the receipts had increased to £11,192. The awards advanced from £4494 in the first year to £5250 in the sixth, and £9500 in the twelfth year. The percentage of expenses to awards was £35·20 in the first four years; 18·30 in the second four years; and in the last four years 14·50. The Council was instructed to investigate the working expenses with a view to the reduction of the cost of management without impairing the efficiency of the work done.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BARTLETT, JACOB H., L.R.C.P.Ed., L.F.P.S.Glas., has been appointed Medical Officer for the Sarratt District of the Watford Union.

BLATHERWICK, CHARLES, M.D., M.R.C.S., has been appointed Government Inspector of Alkali Works in Scotland.

BLUMER, F. MILNES, B.A., M.B., has been appointed Medical Officer of Health for the Borough of Stafford.

BROWN, ARTHUR F. F., M.B.Dur., M.R.C.S., has been appointed Medical Officer for the Rochester District of the Medway Union.

CLAY, AUGUSTUS FREDERIC, M.R.C.S., L.S.A.Lond., has been appointed Casualty Surgeon to the Queen's Hospital, Birmingham.

GODDARD, CHARLES ERNEST, L.R.C.P.Lond., M.R.C.S., A.K.C.Lond., has been appointed Surgeon to the Sudbury Village Hospital; and District Medical Officer and Public Vaccinator for No. 2 Harrow Division of the Hendon Union.

MEADOWS, Dr. ALFRED, has been appointed Consulting Physician Accoucheur to the St. George's and St. James's Dispensary.

Births, Marriages, and Deaths.

BIRTHS.

BRACE.—On the 1st inst., at Queen's-gate-terrace, S.W., the wife of William H. Brace, M.D., of a son.

CAMPBELL.—On the 24th ult., at Princes-gate, Liverpool, the wife of W. Macfie Campbell, M.D., of a son.

DEIGHTON.—On the 27th ult., at St. Bernard's, Hills-road, Cambridge, the wife of Frederick Deighton, M.A., M.R.C.S., of a son.

GILKES.—On the 23rd ult., at Carisbrooke-road, Walthamstow, the wife of Norton Gilbert Gilkes, M.R.C.S., of a son.

GRAHAM.—On the 23rd ult., at Sloane-terrace, Sloane-street, Chelsea, the wife of Arthur Graham, L.R.C.S., L.R.C.P.Ed., of a son.

MCKENZIE.—On the 1st ult., at Musgrave-road, Berea, Durban, Natal, the wife of A. McKenzie, M.B., C.M.Edin., M.R.C.S.Eng., of a son.

RINGER.—On the 21st ult., at Lower Seymour-street, Portman-square, the wife of Deputy Surgeon-General Theobald Ringer, Bengal Army (retired), of a son.

SAWTELL.—On the 24th ult., at Stapleton-hall-road, Stroud-green, N., the wife of T. H. Sawtell, M.D.Lond., of a daughter (stillborn).

SPARROW.—On the 23rd ult., at Haslemere, East Southsea, Hants, the wife of Gordon Sparrow, M.R.C.S., L.R.C.P.Ed., of a son.

STAMPER.—On the 26th ult., at Pembroke Dock, the wife of J. Fenton Stamper, M.D., of a son.

VERDON.—On the 22nd ult., at Brixton-road, S.W., the wife of Walter Verdon, M.D., of a son.

WILLES.—On the 28th ult., at Crooms-hill, Greenwich, the wife of William Willes, L.R.C.P., M.R.C.S., of a son.

WILSON.—On the 28th ult., at Roorkee, India, the wife of Surgeon-Major James Wilson, of twins.

MARRIAGES.

BROWNE—DAVIES.—On the 3rd inst., at Lancaster-gate, W., Surgeon-Major Andrew Lang Browne, M.D., Medical Staff, younger son of John Browne, M.D., of Dundalk, Ireland, to Edith Margaret, only daughter of the late Rev. Thomas M. Davies, M.A., Rector of Llanilid-cum-Llanharran, Glamorganshire.

DAVIS—ATKINSON.—On the 2nd inst., at Christ Church, West Hartlepool, by the Rev. H. E. Savage, Edwin Harry Davis, M.R.C.S., L.S.A.Lond., to Mary, daughter of James Atkinson, M.D., of West Hartlepool.

FAULKNER—BEEBY.—On the 10th ult., at St. John's Church, Colaba, Bombay, Alexander S. Faulkner, Surgeon, I.M.S., 19th Bombay Infantry, to Anne W., daughter of the late Rev. W. Beeby.

STIVENS — DRABBLE. — On the 25th ult., at St. Peter's, Bayswater, B. Lyne Stivens, M.D., M.R.C.S., to Isabel Jemima (Bella), only daughter of G. W. Drabble, Esq., of Pembridge-square, and Los Altos, Sandown, Isle of Wight.

DEATHS.

FALWASSER.—On the 4th ult., at Neemuch, Central India, Francis Falwasser, Surgeon-Major, Army Medical Staff, F.R.C.S., fourth son of the late John Frederick Falwasser, J.P., of Sherborne, Dorsetshire.

FORSTER.—On the 2nd inst., at Upper Grosvenor-street, J. Cooper Forster, M.B.Lond., ex-President of the Royal College of Surgeons, in his 63rd year.

MAGENISS.—On the 1st inst., at The Bolton, Peter Magenis, L.R.C.P.Ed., M.R.C.S., formerly of Euston-road.

SIDEY.—On the 24th ult., at Heriot-row, Edinburgh, James A. Sidey, M.D., aged 61.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, March 8.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Frederick Treves: On the Anatomy of the Intestinal Canal and Peritoneum in the Mammalia.
SOCIETY OF ARTS.—8 P.M. Mr. Boverton Redwood; Petroleum and its Products (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Cases of Aneurysm of the Aorta by Drs. W. H. White, F. de Havilland Hall, and Gilbart Smith.

Tuesday, March 9.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Circulation.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. J. Bland Sutton: A case of General Seborrhœa or "Harlequin Fœtus."—Dr. Paul Chapman: On Cardiography, with special reference to the Relation of the Time of Duration of Ventricular Systole to that of Diastolic Interval.—Dr. Hebb: A case of Tuberculosis of the Skin.
ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8.30 P.M. Dr. J. G. Garson: Exhibition of Instruments for Anthropometric Research.—Mr. Arthur J. Evans: The Flint-Knappers' Art in Albania.—Mr. W. H. Penning: Notes on a few Stone Implements found in South Africa.—Mr. Bruce Foote: Notes on some Prehistoric Finds in India.

Wednesday, March 10.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 3 P.M.; and Saturday, 1 P.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Frederick Treves: On the Anatomy of the Intestinal Canal and Peritoneum in the Mammalia.
SOCIETY OF ARTS.—8 P.M. Mr. E. Price Edwards: The Experiments with Lighthouse Illuminants at the South Foreland.
HUNTERIAN SOCIETY.—8 P.M. Dr. Arthur Davies: Four Cases of Cerebellar Disease.—Dr. Turner: On Arteritis.—Mr. Symonds: Histological Characters of Diphtheritic Membrane.
EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Sir Wm. R. E. Smart: Cholera Epidemics in Ships and Fleets.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. A. D. Michael: Life History of an Acarus, one stage whereof is known as Labidophorus-talpæ, and upon an Unrecorded Species of Disparipes.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown by Dr. Bantock, Dr. Barnes, Mr. Lawson Tait, and others. Mr. Lawson Tait: Notes on two cases of Porro's Operation.

Thursday, March 11.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. W. Boyd Dawkins: The Ancient Geography of Britain.
SOCIETY OF ARTS.—8 P.M. Mr. Leon Warnerke: Films and Paper as Substitutes for Glass in Photography.
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Report of Committee on Sympathetic Ophthalmitis.—Mr. Priestley Smith: On Primary Glaucoma in Relation to Age.—Dr. Bristowe: Hæmorrhage into the Brain attended with Optic Neuritis.—Mr. W. H. Jessop: (1) A New Pupillometer; (2) On Herpes Frontalis affecting the Eye.—Mr. W. Adams Frost: A New Model showing the Movements of the Eye.—Mr. W. Lang (for Dr. J. W. Barrett): A New Microtome.—Dr. Argyll Robertson: On the Operation of Central Blepharoraphy.—Dr. L. Werner: On so-called Central Guttate Choroiditis.—Mr. R. Brudenell Carter: Two New Forms of Perimeter. Living and Card Specimens at 8 P.M.

Friday, March 12.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Frederick Treves: On the Anatomy of the Intestinal Canal and Peritoneum in the Mammalia.
CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Roderick Maclaren (Carlisle): Hernia Cerebri successfully treated by closing the opening in the Skull with a Silver Plate.—Drs. Whipham and Myers: On some Chronic Nervous Sequelæ of Small-pox, especially as affecting the Speech (illustrated by living specimens).—Dr. Samuel West: A case of Baruria in a Woman.—Mr. Jonathan Hutchinson: A case of Necrosis of the Lower Jaw from the medicinal use of Phosphorus.—Dr. Ewart will exhibit a Modification of the Binaural Stethoscope suited for Differential Observations.
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Mr. Reginald Stuart Poole: The Discovery of the Biblical Cities of Egypt.

Saturday, March 13.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. Edward B. Poulton: The Nature and Protective Use of Colour in Caterpillars.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

APPLICATION OF IODOFORM IN DIPHTHERIA.

DR. A. F. RICHMOND of Greenock writes to say that he has cured a very severe case of diphtheria by means of iodoform only. It was applied to the patches on the palate and the fauces (with a camel-hair pencil moistened with mucilage) three times a day. The child also inhaled vapour of iodoform whenever he suffered from dyspnœa, and was invariably relieved by it. The vapour was produced at the lowest possible temperature, so as not to change its chemical and curative properties. The child was unable to swallow for two days previously to being seen by Dr. Richmond, and within half an hour of the application of the iodoform he was able to take a little milk, and afterwards continued to drink with ease. The tongue became clean, and remained so. The child cut three teeth during his illness (which lasted thirteen days) and was slightly salivated towards the termination of the complaint. The salivation was, however, only a little more than might take place in a perfectly healthy child when teething. There was no hyperpyrexia, and the muscular nerve-twigs were not affected; consequently he has had no paralytic symptoms, and is now in good health. Dr. Richmond has also been using iodoform with marked benefit in the treatment of various other complaints—viz., phthisis, erysipelas, herpes, burns, and scalds.

Mr. S. C. Biswas.—It has long been recognised that attacks of asthma may be excited by gastric disorder. See Hyde Salter on Asthma, and Sir Andrew Clark in the *International Journal of Medical Sciences*, Part I., just published.

Dr. Charteris is thanked. The matter scarcely needs comment.

PITYRIASIS CAPITIS.

To the Editor of THE LANCET.

SIR,—I should be glad to hear from any of your readers of a remedy, or treatment that would be likely to prove successful, in a case of pityriasis capitis. The patient, a healthy young woman, has had the disease two years, and has been treated almost constantly during that time.

I am, Sir, yours truly,

Lakefield, Ont., Feb. 15th, 1886. WM. CALDWELL, M.D.

"USE OF IODIDE OF POTASSIUM IN ANEURYSM."

To the Editor of THE LANCET.

SIR,—I observe a letter under the above heading in your issue of to-day (p. 431), by Mr. Lawson Tait. I was always under the impression that heroic doses of the iodide in aneurysm were first employed by Dr. G. W. Balfour of Edinburgh.

I am, Sir, yours faithfully,

Manchester, Feb. 27th, 1886. AN EDINBURGH GRADUATE.

THE ABUSE OF PROVIDENT DISPENSARIES.

Medicus writes to the *Manchester Guardian* complaining of the serious injury done by so-called provident dispensaries which have no proper limit of wages in their conditions of membership. We need not say that we entirely agree with our correspondent.

A Surgeon.—Daniel Oliver's little book (Macmillan); Gerrard's Elements of Materia Medica and Pharmacy (Lewis).

CONSULTING PHYSICIANS' FEES.

To the Editor of THE LANCET.

SIR,—Would you oblige an old subscriber by inserting the following particulars in your columns, as I should be glad of your opinion and that of others in the matter.

Mr. A., a clergyman, aged forty (a curate, but with some private means), who has been lately taking duty in the neighbourhood of London, and had consulted me once or twice, called in January to know if, in my opinion, he was in a fit state of health to accept some clerical duty which had been offered him in Edinburgh. I examined him carefully; and as his lungs were perfectly sound, and he had, in short, no organic mischief whatever, but was clearly hypochondriacal, I urged him to go, telling him the bracing climate would probably set him up, and that, in my opinion, the worst thing he could do was to go on doctoring, as I knew he had been taking remedies for the last six or seven months. He then told me the following history, and I use the *ipsissima verba*. On coming to reside near London in July, he went into a chemist's at the West-end, and asked the name of a good consulting physician. He called on the one recommended, and saw him again the next week. Mr. A. then told him that his income would prevent his paying many visits; but would Dr. ——, he asked, see him twice for the guinea? "Certainly," was the reply, "if Mr. A.'s case proved to be a lengthened one." At the end of the fifth visit, nothing being said as to the reduction of the fee by Dr. ——, Mr. A. reminded him of his kind promise. The following is stated to be his reply: "Oh, I have considered the matter, Mr. A., and I am very sorry that I cannot reduce the fee in your case; but I will do this for you—I will give you extra time for the money, and you can pay me half the fee at the time, and let the other half remain for the present." Mr. A., by his own confession, evidently acquiesced in this, feeling, he said, "he was in the doctor's hands." So matters went on until January, Mr. A. going weekly to see Dr. ——, and in a certain week paying two visits. On receiving the Edinburgh offer, he asked Dr. —— about it. The following is the reply stated to be given: "Edinburgh will not do at all for you; it is too bleak, and you would be very liable to have bronchitis. Besides, who is to look after you as I do if you go there? You see, Mr. A., you are only three-quarters well, and the best thing you can do is to reside near and stay until you are quite recovered. Mr. A., as I have stated, then called to see me, to hear my opinion, which I gave him. Mr. A. also stated that Dr. —— wished particularly to see him the next week, as he had altered the prescription. On examining it, I found the change made in the tonic to be syr. zingib. *vice* syr. limonis. On hearing the above, I requested Mr. A., for his own satisfaction, to see one of the first London consultants, and he consented to do so. I need hardly say, my opinion of Mr. A.'s case was corroborated word for word; and I advised Mr. A. to send half-a-guinea to Dr. ——, which was due, and strongly advised him to pay no more visits. The half fee was sent, and Mr. A. received the following letter and enclosure from Dr. ——.

——— street, ——— square, W., Feb. 17th, 1886.

DEAR SIR,—Thanks for your note enclosing half fee. I am very glad to find by your letter that you are so much better in health, though I fear you are quite well [*sic.* Let us hope the word "not" has been accidentally omitted.] I expected to have seen you as usual, in accordance with our agreement. I have asked my clerk to send you the number of half fees still owing, so that there may be no mistake. (You paid the usual fee, £1 1*s.*, up to 31st of August.)—I am, yours very truly, ———.

——— street, ——— square, W.

Items of the Rev. ——'s account with Dr. ——.
From Sept. 10th, 1885, to Feb. 5th, 1886.

26 visits paid	£27	6 0
11 fees paid	11	11 0
	£15	15 0
By cheque	0	11 0
	£15	4 0

Now, Sir, I should wish to ask: (1) Can a consulting physician recover fees? (2) Considering the particulars of the above case (it being remembered, too, that Dr. —— consented to take half fees if the case was a long one), is my patient morally bound to pay the balance of £15 4*s.*, even though he acquiesced in the proposal? I tell him he need not fear being legally sued for the amount; but he does not desire to do anything shabby in the matter.

I enclose my card, but for obvious reasons sign myself at present

Yours obediently,

London, Feb. 19th, 1886. SUBURBAN.

*** 1. A member of the College of Physicians is prevented by the bye laws of his College from taking legal measures for the recovery of fees.—2. Supposing the above to be an accurate account of this matter—it is, of course, one-sided,—the patient is not morally bound to pay the balance.—ED. L.

INCREASE OF POPULATION IN THE EUROPEAN STATES.

ENOUGH is already known of the result of the German census, taken on December 1st last, to enable German statisticians and publicists to institute comparisons and draw inferences as to the relative growth of population in the various countries of Europe. During the last five years the population of Prussia has increased by 3·79 per cent. This is not as high a rate as during the preceding quinquennial periods. During the eighteen years from 1867 to 1885 the population of Prussia had increased by 17·87 per cent., which gives an annual average increase of 0·918 per cent. The annual rate of increase in Austro-Hungary during the eleven years from 1869 to 1880 (no later figures are available) was only 0·49. In Italy the annual increase for the decade 1871–81 was 0·60 per cent. In France (omitting Algiers and the colonies) the annual rate of increase for the fifteen years from 1866 to 1881 was 0·15 per cent. In Great Britain and Ireland, for the decade from 1871 to 1881, the annual increase was 1·01 per cent. In European Russia, including Finland and the Don Cossacks, in the thirteen years from 1867 to 1880, the average annual increase was 1·38 per cent.

Mr. B. M. H. Rogers.—We are acquainted with the facts of the case, and do not see that a charge of injustice can be maintained.

M.B., L.R.C.S.E. has not enclosed his card.

"MONTROSE SANITARY DISTRICT."

To the Editor of THE LANCET.

SIR,—I hope you will excuse the liberty I am taking, but I cannot help thinking you have been rather too severe on the report of my friend, Dr. Lawrence, of Montrose. Perhaps, however, you are not aware of the position we medical officers of health hold in the North Country, nor the salaries we get. We are, with the exception of Glasgow, Aberdeen, and Edinburgh, all in private practice. Dr. Lawrence has the magnificent salary of £12 for looking after the health of a town of more than 16,000 inhabitants. Surely his report at least equals his salary. My salary for acting as medical officer of health and police surgeon is the princely sum of £10, for which I am expected to do all a police surgeon's duties and attend to the health of nearly 16,000 inhabitants.

I remain, Sir, yours truly,

Forfar, Feb. 27th, 1886. WILLIAM F. MURRAY.

*** We entirely concur with our correspondent as to the inadequacy of the salary referred to, but we must hold that if an officer accepts a post involving the performance of certain generally accepted duties, those duties should be performed and the report of the proceedings of the officer should give evidence that they are performed. So also, the fact of the post having been accepted at an inadequate salary should not be urged as a reason to the contrary. In the case in question we would express no opinion as to the duties not having been performed, but we fail to find evidence of it in so far as the report is concerned.—ED. L.

Nux Vomica.—The graduate of a foreign university has a right to use his title, though his degree is not registrable.

Mr. G. V. Eales.—The paper is marked for insertion.

THE PUBLIC HEALTH ACT.

To the Editor of THE LANCET.

SIR,—Some years since I drew attention to the omission in the Public Health Act referred to by Mr. J. E. Johnson-Ferguson in the House of Commons on the 23rd inst., *vide* "Notes in Parliament" in your issue of the 27th ult. In order to provide a remedy, so far as my own district was concerned, I obtained the insertion of the following brief clause in the Birkenhead Corporation Act, 1881:—"80. The provisions contained in section 126 of the Public Health Act, 1875, shall apply to any person, being in charge of any infectious dead human body, who exposes such body."

I am, Sir, yours truly,

Birkenhead, March 2nd, 1886. FRANCIS VACHER.

Owl.—1. The case is one for consideration rather than for absolute gratuitous attendance.—2. Any reasonable sign or indication of a medical residence for the benefit of those in search of it at night is kind, but garishness is to be avoided.

Dr. Illingworth.—We fear we shall be unable to find room for the letter.

A CURIOUS CASE OF TRIPLE PREGNANCY.

To the Editor of THE LANCET.

SIR,—The following case may be sufficiently interesting to place before your readers.

Mrs. T—— was delivered three months ago of a healthy male child. For four days all went well. On the evening of the fourth day intense labour pains set in, and a substance the size of a pigeon's egg was expelled from the vulva. On examination, this proved to be twins, in a perfectly healthy state. The patient made a good recovery, and three months afterwards the first-born child was healthy and well. This was the patient's first pregnancy.—I am, Sir, yours obediently,

Seven Sisters-rd., N., March 1st, 1886. HAYGARTH ADDISON, L.F.P.S.

THE SHEERNESS MEDICAL BENEFIT SOCIETY.

WE have received a very glowing account of the first annual meeting of the above Society. The financial statement contained in the *Sheerness Guardian* is, however, very far from clear, reading as though the medical officers received £4307 19*s.* 4*d.*, which we assume to be not the true reading.

B. M.—1. Our correspondent is well entitled to the fee he mentions; but the case is one of those cross cases which it is not desirable to take into a court. The mere want of concord between two professional men is an unseemliness which should not be exposed. He will do well to take no notice of the slanderous story. 2. A few drops of tincture of opium with hot fomentations are often the best treatment for a rigid os. The more difficult question in such cases is the administration of ergot, which comes in best when the passages are well dilated.

Mr. G. R. Williams is referred to our advertising columns for the only information we possess on the subject.

Surgeon-Major Gray.—Soon.

THE NEW COLLEGE OF SURGEONS AND PHYSICIANS.

To the Editor of THE LANCET.

SIR,—At the ceremony of laying the foundation-stone of the new College of Surgeons and Physicians by Her Gracious Majesty the Queen I think that a portion of the ground around it should be set aside for medical students, so that we might by our numbers show how much we appreciate the great honour conferred upon us by Her Majesty. Admittance could be by tickets issued at the different hospitals; and I am sure the students would willingly pay a small sum for them, which would defray the expenses. If desired, I feel certain it would be possible to form a guard of honour of those students who are members of the Artists' and other Volunteer corps.

I remain, Sir, yours obediently,

Guy's Hospital, March 1st, 1886. A. RAMSEY LACEY.

Zeno of Elea.—The attention of the corporations whose diplomas are held by the individual should be called to the circular.

W. H. O. may refer to an article on the subject in THE LANCET, March 13th, 1875; also to the number for July 14th, 1883, page 88.

H. Rust.—We cannot insert an appeal without authentication.

Dr. Sansom.—If possible, next week.

SAFETY IN DISPENSING MEDICINES.

To the Editor of THE LANCET.

SIR,—The following is a very simple and, I believe, satisfactory way of reducing to a minimum the dangers of dispensing poisons. Over the corks or stoppers of all the poisons put a closely-fitting capsule (it can be made of common strong paper), which must be removed before the cork or stopper, thus rendering two operations necessary before the drug be dispensed. Dispensers, no matter how busy, will find this check but a trifling inconvenience. Extra business is not, in my opinion, the chief cause of these lamentable mistakes being made. It is probably more likely due to the fits of abstraction the mind is apt to fall into, and which must be very great indeed to get the better of this precaution.

I am, Sir, faithfully yours,

March 1st, 1886. SAMUEL CONSTABLE.

Æ.—The question is legal rather than medical; but our correspondent, we should say, has a strong claim on the parties who sent for him, and on one occasion paid him.

T. G. P. should make application to C. P. Wilson, Esq., St. Katharine's Dock House, Tower-hill.

Dr. R. Diaz Barea (Madrid).—Thanks. We will bear the application in mind.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Clinical Lecture
ON
CATARACT.

Delivered at the Eye Infirmary, Newcastle-on-Tyne.

BY C. S. JEAFFRESON, F.R.C.S. ED.,
SURGEON TO THE INFIRMARY.

(*Concluded from p. 437.*)

WE now, gentlemen, come to consider an operation which took the profession by storm, and for many years held its own in almost every clinic in Europe. I allude to Graefe's modified linear extraction. Like everything which originated in the intellect of the illustrious professor of Berlin, it was sure to command the respect and attention of the profession. The enthusiasm with which it was greeted, and the rapidity with which it threw all other operations into the shade, was only equalled by the success which attended his discovery of iridectomy as a means of treating glaucoma. It cannot, however, be said that the former has stood so well as the latter the inevitable test of time and experience. Year by year the various modifications which were made in it told but too inevitably that it was not giving that satisfaction which its first introduction gave promise of. Each operator in succession varied it somewhat, until at last, as De Wecker wittily expressed it, nothing remained of the operation but the knife. With your permission I will more minutely describe this operation, as its various steps may be made the keystone for our future remarks upon cataract operations in general.....

I wish, gentlemen, to point out what I consider — indeed, what are generally now considered — the disadvantages and dangers of this operation. In the first place, if you have accurately followed my description, it cannot have failed to impress you that it is a tedious and difficult operation. The incision is not easy to make with exactitude, and if extending too far into the sclerotic it gives rise to great dangers. The iridectomy requires great care and skill, and, what to my mind is a great drawback, necessitates an assistant. There is not infrequently a troublesome amount of hæmorrhage from the sclerotic and iris, which obliges the operator to wait for its cessation or continue the further steps of the operation in the dark. The exit of the lens is not always easy. The proximity of the wound to the zonula weakens its support, and there is therefore great danger of loss of vitreous at an early stage, and subsequently in the removal of débris from the anterior chamber. An error at any stage of the operation is difficult to rectify, and sometimes brings about complete failure When all the steps of the operation are successfully completed, the after-progress is certainly more rapid and less complicated. There is no flap to suppurate, and the excised piece of iris precludes in a great measure the dangers of iritis and occlusion of the pupil. On the other hand, an eye which is at all prominent is deformed in appearance. All these are serious defects, and, to my mind, constitute serious drawbacks to the practice of the operation. But there is another which is still more fatal, and that is the frequency with which the operation has been followed by sympathetic ophthalmia. Statistics show that the accident occurs in about 2 per cent. of cases. If the absolute truth could be ascertained, I have little doubt that the percentage would be still higher, but there is naturally a desire to pass over this extremely disagreeable subject.

Weaned from the old flap operation and dissatisfied with the new, ophthalmologists began to look on all sides for some operation which would meet every demand and obviate every danger. Like the search for the philosopher's stone, this effort has been and is likely to be fruitless. No operation can satisfy every demand of facility of execution at the moment and freedom from dangers in the subsequent healing. The principle of linearity, once developed, was by some carried *à outrance*. In conformity with the geometrical necessity that an incision in a spherical body to be truly linear must be in one of its meridians in a direction passing through its centre, Kuchler advised and practised a horizontal section through the centre of the cornea. Strange to say, so inclined are some schools to sacrifice practice to theory, he did not lack supporters, although the results, as must have been foreseen, were attended with most destructive results to the eye as an optical instrument. Further attempts were made with slight modifications in the same direction. Giraud Teulon practised an incision which was linear, but higher than Kuchler's, being transported to the vertical edge of the pupil. Perrin made a short rectangular flap. Notta made his incision in a linear direction, but slightly higher. All these operations, gentlemen, are, I think, undesirable; they are exposed to the fatal objection that in a large proportion of cases they lead to adhesions of the iris to the wound, a condition which is dangerous in the extreme, not unfrequently leading to chronic destructive inflammation of the eye. I have never practised them, and I hope no one does in the present day.

We come now to consider another class of operations. These are typically represented by what is called the Belgian operation. They include Lebrun's, Warlomont's, Liebreich's, and De Wecker's (although I do not here speak of De Wecker's last operation). Though differing in minute details, all these operations have this in common, that they hold a medium position between the old flap and the linear operations. Some approach more nearly to one, some to the other; and in proportion as they do so, speaking generally, they partake in a greater or less degree of the dangers of the type from which they spring. I will now briefly describe these operations.....

The description I have given of cataract operations brings us to a period very closely approaching the present day, and for years I performed the Belgian operation in most of the cases which presented themselves to me. I found that as regards suppuration of the cornea the danger was much diminished; on the other hand, I found that complications from iritic adhesions were more frequent, and gradually I carried my incision higher. Many other operators experienced the same difficulties, and followed the same plan to obviate them. De Wecker has lately most persistently and energetically advocated the performance of what he calls his "small median flap." He forms a flap of the upper third of the cornea, keeping well within the corneo-scleral junction so as to form a small conjunctival flap, with which the wound is covered or protected after the completion of the operation. What are his real claims to call the operation his own I don't know; many others seem also to have called it theirs. In Juler's book you will see it described as Anderson Critchett's. The operation which I usually perform, and have performed for some years, is a kind of medium between the Belgian and De Wecker's. (See Fig. 11.) The incision commences on a little lower plane and is carried into a little higher plane than Lebrun's, and it does not reach quite so high as De Wecker's. It lies wholly within the cornea, and does not trench upon the sclerotic or produce a conjunctival flap, unless accidentally the incision is carried too high. No iridectomy is performed unless a prolapse at the time of operation cannot be easily and immediately reduced, or sometimes in cases where there is reason to believe much cortical matter remains in the anterior chamber, in which case a small iridectomy is made, as it much facilitates a clearance of the anterior chamber. In a large proportion of cases, as I shall show you after the lecture, a clear central movable pupil is obtained. In those in which an iridectomy has been performed the shape of the pupil will vary with the amount of iris that has been removed. The advantages of this operation are:—1. Its easy performance. 2. It does not require an assistant. 3. In a large proportion of cases it leaves a clear circular pupil like the old flap operation. 4. It is very little liable to suppuration. 5. It is never, in my experience, followed by sympathetic iritis. 6. It rapidly heals, and is a good operation for persons who cannot remain long under treatment. Its disadvantages are that the incision is sometimes a little small, and the delivery of the lens somewhat tedious. (See Fig. 10.) As a result, generally rather more cortical débris is left in the anterior chamber than is desirable, but this may be removed by careful manipulation. And here, gentlemen, to my mind, an important question arises—To what extent should we carry this cleansing process? Ladies who take the longest time

Digitized by Google

over their toilettes do not always look the best; and in my experience a tedious toilette after a cataract operation sometimes leads to disastrous results. Experience can alone indicate the cases in which it is advisable not to manipulate too much.
